13. ABSTRACT

An iteration method for solving the implicit difference equations associated with three-dimensional nonlinear parabolic differential equations is derived and analyzed. The method is applied to the high Reynolds number laminar viscous flow around a cone at high angle of attack. The requirements which must be met to ensure convergence of the iterations are obtained. In addition, an analysis of the stability of the difference equations is presented and discussed. The numerical results are compared with experimental data for a 10-deg cone at 12-deg angle of attack, and a 5.6-deg cone at 8-deg angle of attack. The agreement is very good.

A description of the associated computer program is contained in the appendices.

FOREWORD

This report is published by The Aerospace Corporation, El Segundo, California, under Air Force Contract No. F04701-73-C-0074. This report was prepared by the Information Processing Division, Engineering Science Operations, at the request of the Reentry Systems Division, Development Operations.

This report, which documents research carried out from April 1970 to December 1972 was submitted for review and approval on 13 September 1973 to Capt. A. Klingler, RSSE.

Approved by

A.R. Sims, Director

SECTION I

INTRODUCTION

In recent years there has been a tremendous increase in numerical solutions for three-dimensional flow problems. This increase has been due to the rapid growth in the storage capacity and speed of computers. The primary effort in computing three-dimensional flows has been in using explicit methods. Explicit methods, although relatively easy to program, consume excessive amounts of computer time due to stability restrictions on step sizes. Even a DuFort-Frankel (Ref. 1) or Crocco (Ref. 2) scheme uses a considerable amount of time when the mesh spacing is small, as is necessary for accuracy with high speed, high Reynolds number laminar flow problems. Therefore, for many flow problems it is desirable to use an implicit technique to solve the governing partial differential equations. Implicit methods have the advantage of being stable, consistent, and accurate for reasonable stepsizes. The major drawback is the size and complexity of the computer program which must be written and the storage requirements due to the necessity of solving large systems of equations. Alternating direction implicit methods (Ref. 3), although reducing the size of the system of equations which must be solved for three-dimensional problems, double the complexity of the computer code which must be developed.

In this report, a method of solving the large system of algebraic equations which result from the implicit differencing of three-dimensional flow equations is developed. For a typical problem, the implicit differencing may result in a system of 6000 or more algebraic equations. A method of solving these equations which does not require excessive computer storage and that yields accurate results is presented. The method is similar to the "predictor corrector" multiple iteration technique described by Rubin and Lin (Ref 4).

The numerical approach begins with an implicit differencing of the system of nonlinear partial differential equations. The nonlinear algebraic

equations resulting from this differencing are first linearized, and the resulting linear algebraic equations are then solved using a Gauss-Seidel (Ref. 5) iteration method. The details of the method are given in Section II for a simple model equation. Because of the necessity of iterating, which results from the numerical approach, the convergence of the iteration should be considered. This question is also analyzed in Section II for the model equation.

In Section III, the numerical technique which is developed is applied to the solution of an approximate system of three-dimensional equations which has been developed to predict the flow fields around cones at high angles of attack. This approximate system of viscous equations has been derived from the steady Navier-Stokes equations by assuming the gradients of the shear stress in the streamwise direction are much smaller than the gradients in the normal and circumferential directions (Ref. 6). The resulting equations are similar to those developed by Lin and Rubin (Ref. 7) to solve the sharp tip, low Reynolds number region for a cone at angle of attack. The resulting system of equations is first order in x and second order in y and ϕ. The convergence and stability of the system of equations are discussed.

Solutions to the system of equations are presented for two cases in Section IV. The first, a 10-deg half angle cone at 12-deg angle of attack and a freestream Mach number of 8; and the second, a 5.6-deg half angle cone at 8-deg angle of attack and a freestream Mach number of 14.2. The conditions for these cases correspond closely to experimental data obtained by Tracy (Ref. 8) and Stetson and Ojdana (Ref. 9). Comparisons of the numerical results with the experimental data are shown.

SECTION II

NUMERICAL TECHNIQUE

In this section, the numerical technique is developed and analyzed. To illustrate the approach, the following three-dimensional partial differential equation is considered:

$$\frac{\partial u}{\partial x} + a\frac{\partial u}{\partial \eta} + b\frac{\partial u}{\partial \Phi} - c\frac{\partial^2 u}{\partial \eta^2} - d\frac{\partial^2 u}{\partial \Phi^2} = 0 \qquad c,\ d \geq 0 \tag{1}$$

This equation is representative of the viscous flow equation. For three-dimensional steady flow, $a = v/u$, $b = w/ur$, $c = \mu/Re\rho u$, $d = \mu/Re\rho ur^2$.

The following finite difference approximation formulas are used:

$$\frac{\partial u}{\partial x} = (u_{j+1,k,\ell} - u_{j,k,\ell})/\Delta x$$

$$\frac{\partial u}{\partial \eta} = (u_{j+1,k+1,\ell} - u_{j+1,k-1,\ell})/2\Delta\eta$$

$$\frac{\partial^2 u}{\partial \eta^2} = (u_{j+1,k+1,\ell} - 2u_{j+1,k,\ell} + u_{j+1,k-1,\ell})/\Delta\eta^2 \tag{2}$$

$$\frac{\partial u}{\partial \Phi} = (u_{j+1,k,\ell+1} - u_{j+1,k,\ell-1})/2\Delta\Phi$$

$$\frac{\partial^2 u}{\partial \Phi^2} = (u_{j+1,k,\ell+1} - 2u_{j+1,k,\ell} + u_{j+1,k,\ell-1})/\Delta\Phi^2$$

where $u_{j,k,\ell}$ is the value of u at the grid point j,k,ℓ.

In addition, in the more general case, a cross derivative term appears. For completeness the difference formula is defined.

$$\frac{\partial^2 u}{\partial\eta\partial\Phi} = [(u_{j+1,k+1,\ell+1} - u_{j+1,k-1,\ell+1}) - (u_{j+1,k+1,\ell-1} - u_{j+1,k-1,\ell-1})]/4\Delta\eta\Delta\Phi \qquad (3)$$

The scheme for solving the differential equation is then completely implicit. To obtain $u_{j+1,k,\ell}$ (solution known at j) a linear system of equations of order K * L must be solved.

The method proposed to solve this system of linear equations is the line Gauss-Seidel iteration method mentioned in Fox (Ref. 5) and Isaacson and Keller (Ref. 10). To be specific, suppose $u^n_{j+1,k,\ell}$ is a guess to the solution of the difference equations where n denotes the iteration number. Then the correction $\bar{u}_{j+1,k,\ell}$ which must be added to $u^n_{j+1,k,\ell}$ to give the solution satisfies, after rearranging

$$\left(-\frac{a}{2\Delta\eta} - \frac{c}{\Delta\eta^2}\right)\bar{u}_{j+1,k-1,\ell} + \left(\frac{1}{\Delta x} + \frac{2c}{\Delta\eta^2} + \frac{2d}{\Delta\Phi^2}\right)\bar{u}_{j+1,k,\ell} + \left(\frac{a}{2\Delta\eta} - \frac{c}{\Delta\eta^2}\right)\bar{u}_{j+1,k+1,\ell}$$

$$= -\frac{\partial u^n}{\partial x} - a\frac{\partial u^n}{\partial\eta} - b\frac{\partial u^n}{\partial\Phi} + c\frac{\partial^2 u^n}{\partial\eta^2} + d\frac{\partial^2 u^n}{\partial\Phi^2} - \frac{b}{2\Delta\Phi}\left(\underline{\bar{u}_{j+1,k,\ell+1}} - u_{j+1,k,\ell-1}\right)$$

$$+ \frac{d}{\Delta\Phi^2}\left(\underline{\bar{u}_{j+1,k,\ell+1}} + \bar{u}_{j+1,k,\ell-1}\right) \qquad (4)$$

If the underlined terms on the right hand side of Eq. (4) are ignored and the resulting equations are solved in the order $\ell = 1, 2, \ldots L$, using the boundary conditions at $\ell = 1$, then the approximate solution denoted by $\bar{U}_{j+1,k,\ell}$ should be close to $\bar{u}_{j+1,k,\ell}$. Taking $u^{n+1}_{j+1,k,\ell} = u^n_{j+1,k,\ell} + \bar{U}_{j+1,k,\ell}$ as a new guess to the solution of Eq. (1) the process is repeated to obtain $u^{n+2}_{j+1,k,\ell}$ and so on until convergence is achieved.

The above method has the advantage that L systems of order K must be solved instead of one of order L * K. This saves time and storage.

A seeming disadvantage is that iteration is required. That is, solving L systems of order K just produces a "guess" to the solution of Eq. (4). To obtain a better "guess" the L systems have to be solved again, etc.

However for nonlinear problems this is not a disadvantage. To solve a nonlinear system of equations, some form of linearization must be done (e.g., Newton-Raphson method) and then iteration is done to obtain an accurate solution. The line Gauss-Seidel method may be used to solve the linear system, and instead of iterating to convergence the first iterate is taken as the next iterate in the nonlinear sequence of iterates. Experience has shown that the convergence of the nonlinear iterates is not severely hindered by not solving exactly for the iterate.

Once the iterations have converged then the method is completely implicit and so the single linear Eq. (1) is stable and consistent. The primary question to be answered is whether or not the iterates converge. To consider the convergence question write the difference equation [Eq. (4)] as

$$u^{n+1}_{j+1,k,\ell} + \frac{c\Delta x}{2\Delta\eta}\left(u^{n+1}_{j+1,k+1,\ell} - u^{n+1}_{j+1,k-1,\ell}\right) + \frac{b\Delta x}{2\Delta\Phi}\left(u^{n}_{j+1,k,\ell+1} - u^{n+1}_{j+1,k,\ell-1}\right)$$
$$- \frac{c\Delta x}{\Delta\eta^2}\left(u^{n+1}_{j+1,k+1,\ell} - 2u^{n+1}_{j+1,k,\ell} + u^{n+1}_{j+1,k-1,\ell}\right)$$
$$- \frac{d\Delta x}{\Delta\Phi^2}\left(u^{n}_{j+1,k,\ell+1} - 2u^{n+1}_{j+1,k,\ell} + u^{n+1}_{j+1,k,\ell-1}\right) = u_{j,k,\ell} \qquad (5)$$

The above equation is a difference equation with difference index n. To determine under what conditions the solution converges as $n \to \infty$ the Fourier series method as presented in Richtmyer and Morton (Ref. 11) may be used. That is, substitute $\lambda e^{i(m_1\ell\Delta\Phi + m_2 k\Delta\eta)}$ for $u^{n+1}_{j+1,k,\ell}$ and $e^{i(m_1\ell\Delta\Phi + m_2 k\Delta\eta)}$ for $u^{n}_{j+1,k,\ell}$. The term $u_{j,k,\ell}$ is ignored since it is independent of n, and

the resulting equation is solved for λ. The iterates will converge if $|\lambda| < 1$. For Eq. (5) the amplification factor λ is

$$\lambda = \frac{-\left(\frac{b\Delta x}{2\Delta\Phi} - \frac{d\Delta x}{\Delta\Phi^2}\right)(\cos m_1\Delta\Phi + i\sin m_1\Delta\Phi)}{1 - \left(\frac{b\Delta x}{2\Delta\Phi} + \frac{d\Delta x}{\Delta\Phi^2}\right)\cos m_1\Delta\Phi - \frac{c\Delta x}{\Delta\eta^2}(\cos m_2\Delta\eta - 1) + \frac{2d\Delta x}{\Delta\Phi^2} + \frac{a\Delta x}{\Delta\eta} i\sin m_2\Delta\eta + \left(\frac{b\Delta x}{2\Delta\Phi} + \frac{d\Delta x}{\Delta\Phi^2}\right) i\sin m_1\Delta\Phi} \tag{6}$$

After some manipulation it can be shown that $|\lambda| < 1$ if $\Delta x < \frac{\Delta\Phi}{|b|}$.

If the values of u at $\ell - 1$ were evaluated at the nth iterate instead of the $n+1^{th}$, this would be the line Jacobi elimination method (Ref. 10) and the convergence criterion would be the same. It is line Jacobi elimination that Rubin and Lin (Ref. 4) studied; however, instead of considering convergence they looked at what would happen if just one or two iterations were carried out. They found that the equations were not quite consistent and for the method to be stable as a marching scheme in x there was a restriction on Δx depending on the number of iterations performed. For one iteration, the stability restriction was the same as the above derived convergence restriction. (Rubin and Lin considered the case where $c = 0$.) The question may be asked why it is necessary to iterate to convergence (which may require four or five iterations) instead of iterating only once or twice. Iterating to convergence produces consistency, and in nonlinear equations it is necessary to iterate several times to obtain an accurate and stable solution to the nonlinear difference equations.

The rates of convergence for the line Jacobi method and the line Gauss-Seidel method have been studied for elliptic problems (Ref. 10) and it has been found that the line Gauss-Seidel method converges twice as fast as the line Jacobi method. The results for the above simple parabolic case are analogous.

If a DuFort-Frankel scheme or a Crocco scheme or some other modified explicit formula (modified to remove the diffusive stability requirement)

is used, there are two convective stability requirements. The above scheme eliminates one convective Δx restriction. For problems which permit very unequal meshes in the two directions, as for many flow problems, this may permit much greater step sizes.

In the next section, the differencing described above is applied to a complicated system of three-dimensional viscous flow equations which have been developed to solve for the flow field around a cone at angle of attack.

SECTION III

APPLICATION TO CONE AT ANGLE OF ATTACK

A. GOVERNING EQUATIONS

The numerical technique which was developed in the previous section will be applied to a complicated system of three-dimensional viscous flow equations which have been derived to predict the flow around a cone at angle of attack. The system of equations has been derived from the steady Navier-Stokes equations by assuming the gradients of the shear stress in the streamwise direction are much smaller than the gradients in the normal and circumferential directions (Ref. 6). The coordinate system used in the development of the equations is illustrated in Figure 1.

The resulting nondimensional equations are listed below:

Continuity equation

$$\frac{\partial \rho u r}{\partial x} + \frac{\partial \rho v r}{\partial y} + \frac{\partial \rho w}{\partial \Phi} = 0 \tag{7}$$

x-momentum equation

$$\frac{\partial \rho u^2 r}{\partial x} + \frac{\partial \rho u v r}{\partial y} + \frac{\partial \rho w u}{\partial \Phi} - \rho w^2 \sin\theta + r \frac{\partial p}{\partial x}$$

$$= \frac{r}{Re} \left\{ \frac{\partial}{\partial y}\left(\mu \frac{\partial u}{\partial y}\right) + \frac{1}{r^2} \frac{\partial}{\partial \Phi}\left(\mu \frac{\partial u}{\partial \Phi}\right) + \frac{\mu}{r} \frac{\partial u}{\partial y} \cos\theta \right\} \tag{8}$$

Preceding page blank

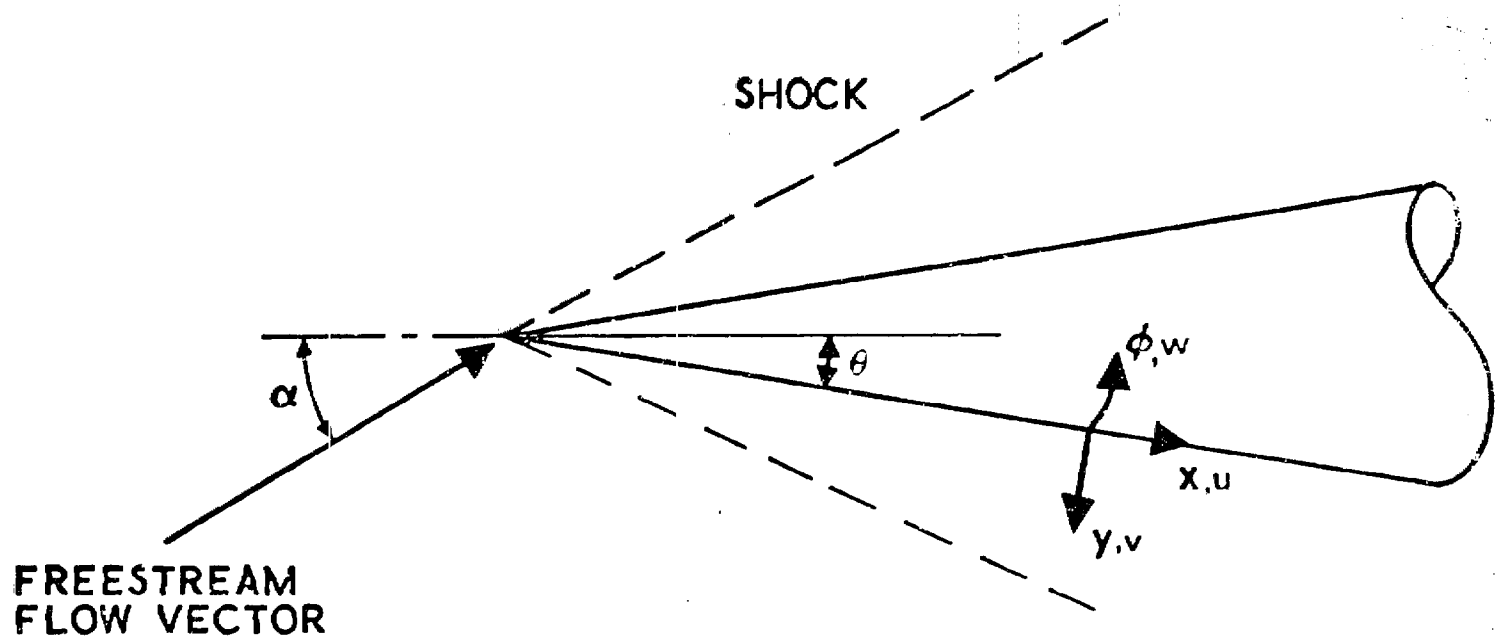

Figure 1. Coordinate System

y-momentum equation

$$\frac{\partial \rho u v r}{\partial x} + \frac{\partial \rho v^2 r}{\partial y} + \frac{\partial \rho v w}{\partial \Phi} - \rho w^2 \cos\theta + r \frac{\partial p}{\partial y}$$

$$= \frac{r}{Re} \left\{ \frac{4}{3} \frac{\partial}{\partial y} \left(\mu \frac{\partial v}{\partial y} \right) + \frac{1}{r^2} \frac{\partial}{\partial \Phi} \left(\mu \frac{\partial v}{\partial \Phi} \right) \right.$$

$$\left. + \frac{1}{r} \frac{\partial}{\partial \Phi} \left(\mu \frac{\partial w}{\partial y} \right) - \frac{2}{3} \frac{\partial}{\partial y} \left(\frac{\mu}{r} \frac{\partial w}{\partial \Phi} \right) \right\} \tag{9}$$

Φ-momentum equation

$$\frac{\partial \rho u w r}{\partial x} + \frac{\partial \rho v w r}{\partial y} + \frac{\partial \rho w^2}{\partial \Phi} + \rho u w \sin\theta + \rho v w \cos\theta + \frac{\partial p}{\partial \Phi}$$

$$= \frac{r}{Re} \left\{ \frac{\partial}{\partial y} \left(\frac{\mu}{r} \frac{\partial v}{\partial \Phi} \right) - \frac{2}{3r} \frac{\partial}{\partial \Phi} \left(\mu \frac{\partial v}{\partial y} \right) + \frac{\partial}{\partial y} \left(\mu \frac{\partial w}{\partial y} \right) + \frac{4}{3r^2} \frac{\partial}{\partial \Phi} \left(\mu \frac{\partial w}{\partial \Phi} \right) \right\} \tag{10}$$

Energy equation

$$\frac{\partial \rho u r h}{\partial x} + \frac{\partial \rho v r h}{\partial y} + \frac{\partial \rho w h}{\partial \Phi} = (\gamma - 1) M_\infty^2 \, r \left\{ u \frac{\partial p}{\partial x} + v \frac{\partial p}{\partial y} + \frac{w}{r} \frac{\partial p}{\partial \Phi} \right\}$$

$$+ \frac{\mu r (\gamma - 1) M_\infty^2}{Re} \left\{ \left(\frac{\partial u}{\partial y} \right)^2 + \frac{1}{r^2} \left(\frac{\partial u}{\partial \Phi} \right)^2 + \left(\frac{\partial w}{\partial y} \right)^2 + \frac{4}{3r^2} \left(\frac{\partial w}{\partial \Phi} \right)^2 \right.$$

$$\left. + \frac{4}{3} \left(\frac{\partial v}{\partial y} \right)^2 + \frac{1}{r^2} \left(\frac{\partial v}{\partial \Phi} \right)^2 - \frac{4}{3r} \frac{\partial v}{\partial y} \frac{\partial w}{\partial \Phi} + \frac{2}{r} \frac{\partial v}{\partial \Phi} \frac{\partial w}{\partial y} \right\}$$

$$+ \frac{r}{Re \, Pr} \left\{ \frac{1}{r} \frac{\partial}{\partial y} \left(r \mu \frac{\partial h}{\partial y} \right) + \frac{1}{r^2} \frac{\partial}{\partial \Phi} \left(\mu \frac{\partial h}{\partial \Phi} \right) \right\} \tag{11}$$

where the perfect gas equation of state is used to relate the density to the pressure and enthalpy

$$\rho = \gamma M_\infty^2 \frac{p}{h} \tag{12}$$

and Sutherland's law is used to relate the viscosity to the enthalpy

$$\mu = \sqrt{h}\ \frac{1+S}{1+S/h} \tag{13}$$

A constant Prandtl number and specific heat will also be assumed.

The above equations are similar to those used by Lin and Rubin (Ref. 7) except the terms associated with $r \to 0$ have been dropped. These terms are important only near the tip at low Reynolds number. We will be interested in solving the higher Reynolds number cases downstream of the tip region. The following boundary conditions at the cone surface are used.

$$u = v = w = 0$$

$$h_w = \text{specified constant} \tag{14}$$

$$\left(\frac{\partial p}{\partial y}\right)_w = \frac{1}{Re}\left(\frac{4}{3}\,\mu\,\frac{\partial^2 v}{\partial y^2} + \frac{1}{r}\,\frac{\mu}{3}\,\frac{\partial^2 w}{\partial y \partial \Phi}\right)$$

The last equation has been obtained from the v-momentum equation using the condition $(\partial v/\partial y)_w = 0$ which is required in order that the continuity equation is satisfied at the wall.

The following difference formulas are used in the $(\partial p/\partial y)_w$ equation:

$$\left(\frac{\partial^2 w}{\partial y \partial \Phi}\right)_w = \left.\frac{\partial w}{\partial \Phi}\right|_{k=2} / \Delta y$$

$$\left(\frac{\partial^2 v}{\partial y^2}\right)_w = 2 v_{k=2} / \Delta y^2$$

and are obtained from Taylor series expansions in the normal direction of $\left.\frac{\partial w}{\partial \Phi}\right|_{k=2}$ and $v_{k=2}$.

The Rankine-Hugoniot jump conditions are applied at the shock boundary. In the body-oriented coordinate system (Figure 1) they are

Conservation of mass equation

$$(u_\infty - \rho_K u_K)\frac{\partial \xi}{\partial x} - (v_\infty - \rho_K v_K) + (w_\infty - \rho_K w_K)\frac{1}{r}\frac{\partial \xi}{\partial \Phi} = 0 \tag{15}$$

Conservation of normal momentum equation

$$\frac{\left(u_\infty \frac{\partial \xi}{\partial x} - v_\infty + w_\infty \frac{1}{r}\frac{\partial \xi}{\partial \Phi}\right)^2}{\left(\frac{\partial \xi}{\partial x}\right)^2 + 1 + \left(\frac{1}{r}\frac{\partial \xi}{\partial \Phi}\right)^2} + p_\infty = p_K + \frac{\left(u_K \frac{\partial \xi}{\partial x} - v_K + w_K \frac{1}{r}\frac{\partial \xi}{\partial \Phi}\right)^2}{\left(\frac{\partial \xi}{\partial x}\right)^2 + 1 + \left(\frac{1}{r}\frac{\partial \xi}{\partial \Phi}\right)^2} \tag{16}$$

Conservation of tangential velocities equations

$$(u_\infty - u_K)\left[1 + \left(\frac{1}{r}\frac{\partial \xi}{\partial \Phi}\right)^2\right] + (v_\infty - v_K)\frac{\partial \xi}{\partial x} - (w_\infty - w_K)\frac{1}{r}\frac{\partial \xi}{\partial \Phi}\frac{\partial \xi}{\partial x} = 0$$

$$(v_\infty - v_K)\frac{1}{r}\frac{\partial \xi}{\partial \Phi} + (w_\infty - w_K) = 0 \tag{17}$$

Conservation of energy equation

$$\frac{(\gamma-1)M_\infty^2}{2} V_\infty^2 + h_\infty = h_K + \frac{(\gamma-1)M_\infty^2}{2}\left(u_K^2 + v_K^2 + w_K^2\right) \tag{18}$$

The subscript K denotes the value of the variable just inside the shock. In order to uniquely determine the six unknowns ξ, u_K, v_K, w_K, p_K, h_K, the above five equations must be augmented with a sixth equation. A one-sided differencing of the continuity equation provides the sixth equation. Full justification and discussion of the above equations and boundary conditions are presented in Ref. 6).

Since the fluid flow is symmetric about the plane $\Phi = 0$ and $\Phi = \pi$, the equations used will be solved for $0 \leq \Phi \leq \pi$ where the symmetry conditions

$$\frac{\partial}{\partial \Phi}(u, v, p, h, \xi) = 0; \quad w = \frac{\partial^2 w}{\partial \Phi^2} = 0 \tag{19}$$

are used at $\Phi = 0$ and $\Phi = \pi$. (Note: $\Phi = 0$ is the windward side.)

The shock distance is to be solved for from the Rankine-Hugoniot jump conditions. In a rectangular y-Φ grid the shock may not fall on a mesh point so that mesh points would have to be moved or added to accommodate the shock. Thus, the transformation $\eta = y/\xi(x, \Phi)$ is made. The resulting equations are then solved for $0 \leq \eta \leq 1$, $0 \leq \Phi \leq \pi$, where $\eta = 0$ corresponds to the cone and $\eta = 1$ corresponds to the shock. The shock distance ξ appears in all the equations and in order to keep the matrix of coefficients obtained from the difference form of the equation in block tri-diagonal form, a sixth equation

$$\frac{\partial \xi}{\partial \eta} = 0 \tag{20}$$

is differenced. Thus the problem to be solved consists of six differential equations, six boundary conditions at each of the positions $\eta = 0$ and $\eta = 1$ and two symmetry conditions at $\Phi = 0$ and $\Phi = \pi$ [Eqs. (7) through (20)] in the six unknowns u, v, w, p, h, ξ.

If initial conditions were known, a marching scheme in x could be used to solve the equations. An explicit method would not work since, as shown by Baum and Denison [Eq. (12)] for the axisymmetric problem, it is not possible to solve for $\partial u/\partial x$, $\partial v/\partial x$, $\partial w/\partial x$, $\partial p/\partial x$, $\partial h/\partial x$, at $M_x = 1$. Even if this difficulty could be overcome the diffusive stability requirement would be too strict. Since the gradients in the normal direction are much larger than in the circumferential direction, the normal mesh will be much finer than the circumferential mesh. Thus a method that is implicit in the normal direction should be more efficient than a modified explicit differencing such as DuFort-Frankel or Crocco. Accurate solutions at each x-station are desired

and since the equations are very nonlinear they require iteration for accuracy. The method proposed in the previous section is most appropriate for this problem.

An alternating direction implicit technique was tried, with iteration to handle the nonlinearities. It was found that near $u = 0$ and $M_x = 1$, the equations for the implicit in Φ step were ill-conditioned and meaningful solutions could not be obtained. The $M_x = 1$ difficulty was overcome by evaluating the $\partial p/\partial x$ term backwards in x in the x-momentum and energy equations. However, the $u = 0$ difficulty remained.

The implicit difference equations [Eqs. (2) and (3)] are substituted into the partial differential equations and a system of nonlinear algebraic equations result. There are many ways to linearize such a system. Since convergence is guaranteed provided the initial guess is close enough, and because the convergence is quadratic, the Newton-Raphson method is used to solve these equations. That is, the nonlinear terms are expanded in a Taylor series and terms higher than first order are dropped. It is known that this iteration procedure converges provided the initial guess is close enough to the solution. It was found that linearly extrapolating the solution at the previous two x stations gives a satisfactory initial guess. To see what linearization does to various terms let $\bar{f}$ represent the increment to be added to the known iterate and the superscript n denote that iterate. A few sample expressions are

$$\frac{\partial \rho u r}{\partial x} = \left(\frac{\partial \rho u r}{\partial x}\right)^n + \bar{u}\,\frac{(\rho r)^n}{\Delta x} + \frac{(u r)^n}{\Delta x}\left(\frac{\partial \rho}{\partial p}\,\bar{p} + \frac{\partial \rho}{\partial h}\,\bar{h}\right) + \bar{r}\,\frac{(\rho u)^n}{\Delta x}$$

$$\frac{\partial \rho w}{\partial \Phi} = \left(\frac{\partial \rho w}{\partial \Phi}\right)^n + \frac{\partial(\rho^n \bar{w})}{\partial \Phi} + \frac{\partial}{\partial \Phi}\left(w^n\,\frac{\partial \rho}{\partial p}\,\bar{p} + w^n\,\frac{\partial \rho}{\partial h}\,\bar{h}\right)$$

$$\mu\,\frac{\partial^2 v}{\partial \Phi^2} = \left(\mu\,\frac{\partial^2 v}{\partial \Phi^2}\right)^n + \bar{h}\left(\frac{d\mu}{dh}\,\frac{\partial^2 v}{\partial \Phi^2}\right)^n + \mu^n\,\frac{\partial^2 \bar{v}}{\partial \Phi^2}$$

The $\bar{r}$ term above is $\bar{r} = \bar{\xi}\,\eta\cos\Phi$, since $x_{j+1}\sin\theta$ is known. The linear system of equations obtained are solved for $\bar{u}, \bar{v}, \bar{w}, \bar{p}, \bar{h}$, and $\bar{\xi}$ using the line Gauss-Seidel method described in the previous section. However, only one iteration of the line Gauss-Seidel method is performed. The approximate solutions so obtained are then used to obtain the next guess to the nonlinear system.

For this flow problem the L systems of equations that must be solved to obtain one Gauss-Seidel iterate are of order 6 * K since there are six variables involved. The matrix of coefficients is of block tridiagonal form. An efficient method for solving such systems is presented in Isaacson and Keller (Ref. 10) and was used by Rubin and Lin (Ref. 4) and also in the present analysis.

B. CONVERGENCE AND STABILITY

The questions of convergence and stability must be investigated for the system of flow equations. To consider convergence, the equations are simplified. First the equations are written in a different form by expanding the derivative expressions and subtracting the continuity equation from the momentum equation and the energy equation. For simplicity it is assumed that $\mu/Pr = 4/3\ \mu = \mu$. The viscosity is assumed to be constant and the shock distance is assumed to be known. Since the iteration is primarily for the Φ derivative terms, then all terms not involving derivatives with respect to Φ exclusively are ignored. The following equations are left.

$$\frac{\partial u}{\partial x} + \underline{\frac{1}{\rho u}\frac{\partial p}{\partial x}} + \frac{w}{ur}\frac{\partial u}{\partial \Phi} - Re^{*}\frac{\partial^2 u}{\partial \Phi^2} = 0$$

$$\frac{\partial v}{\partial x} + \frac{w}{ur}\frac{\partial v}{\partial \Phi} - Re^{*}\frac{\partial^2 v}{\partial \Phi^2} = 0 \qquad (21a)$$

$$\frac{\partial w}{\partial x} + \frac{w}{ur}\frac{\partial w}{\partial \Phi} - Re^{*}\frac{\partial^2 w}{\partial \Phi^2} + \frac{h}{ur\gamma M_{\infty}^2 p}\frac{\partial p}{\partial \Phi} = 0$$

$$\frac{\partial p}{\partial x} + \frac{p}{u}\frac{\partial u}{\partial x} - \frac{p}{h}\frac{\partial h}{\partial x} + \frac{w}{ur}\frac{\partial p}{\partial \Phi} + \frac{p}{ur}\frac{\partial w}{\partial \Phi} - \frac{w}{ur}\frac{p}{h}\frac{\partial h}{\partial \Phi} = 0$$

$$\frac{\partial h}{\partial x} - \underline{\frac{\gamma-1}{\gamma}\frac{h}{p}\frac{\partial p}{\partial x}} + \frac{w}{ur}\frac{\partial h}{\partial \Phi} - Re^{*}\frac{\partial^2 h}{\partial \Phi^2} - \frac{\gamma-1}{\gamma}\frac{w}{ur}\frac{h}{p}\frac{\partial p}{\partial \Phi} = 0 \tag{21b}$$

where

$$Re^{*} = \frac{1}{Re}\frac{uh}{ur^2\gamma M_{\infty}^2 p}$$

To further simplify the analysis, assume that all coefficients of the derivative terms are constant, and that the mesh spacings are constant Δx, Δy, and $\Delta\Phi$ in the x, y, and Φ directions, respectively. After differencing and some rearranging, the line Gauss-Seidel iteration method reduces the difference equation for u at each mesh point to

$$u^{n+1}_{j+1,k,\ell} + \frac{1}{\rho u}p^{n+1}_{j+1,k,\ell} + \frac{w}{ur}\frac{\Delta x}{2\Delta\Phi}\left(u^{n}_{j+1,k,\ell+1} - u^{n+1}_{j+1,k,\ell-1}\right)$$

$$- Re^{*}\frac{\Delta x}{\Delta\Phi^2}\left(u^{n}_{j+1,k,\ell+1} - 2u^{n+1}_{j+1,k,\ell} + u^{n+1}_{j+1,k,\ell-1}\right) = u_{j,k,\ell} + \frac{1}{\rho u}p_{j,k,\ell} \tag{22}$$

with similar expressions for the other equations, where the superscript n denotes the known iterate, the superscript n+1 denotes the next (unknown) iterate, and the right hand side of the equations are at j and so are independent of the iterate.

The convergence of the solution of the system of difference equations represented by Eq. (22) can be determined using the Fourier series method as presented in Ref. 11. The solutions will converge if the eigenvalues of the associated amplification matrix are less than one in absolute value. To

obtain the eigenvalues substitute $u_o e^{im\ell\Delta\Phi}$ and $\lambda u_o e^{im\ell\Delta\Phi}$ for $u^n_{j+1,k,\ell}$ and $u^{n+1}_{j+1,k,\ell}$, and similarly for v, w, p, h; this gives five linear equation in u_o, v_o, w_o, p_o, and h_o, and the eigenvalues of the amplification matrix are those values of λ for which the determinant of the coefficient matrix is zero.

For the above system it has been found in regions of the flow where M_x is near one or less than one, that some of the eigenvalues of the amplification matrix are greater than one, in absolute value, independent of Δx and $\Delta\Phi$. However, if the $\partial p/\partial x$ term in the x-momentum and energy equation are differenced backwards in x, i.e.

$$\frac{\partial p}{\partial x} = \frac{p_{j,k,\ell} - p_{j-1,k,\ell}}{\Delta x} \tag{23}$$

as suggested by Ohrenberger and Baum (Ref. 13), or set equal to zero as suggested by Rubin and Lin (Ref. 14), then convergence criteria can be obtained. Doing either of the above modifications causes the difference expressions representing the underlined terms in Eq. (21) to be independent of the iteration index n. Thus, the first and second difference equations are uncoupled from the rest of the system and are similar to the simple equation in Section II. Therefore $|\lambda| < 1$ if

$$\Delta x < \left|\frac{ur}{w}\right| \Delta\Phi \tag{24}$$

The remaining three equations are studied using the Fourier series method. If the determinant of the associated three by three matrix of coefficients is set equal to zero, it can be found that a third value of λ is the same as the first two above, and so Eq. (24) must be satisfied. The remaining two values satisfy a complicated quadratic equation. To simplify the analysis the first and second derivative terms are handled separately. For second derivative terms only, it can be easily shown that both roots of the

quadratic equation are less than one in absolute value. For first derivative terms only, it can be shown after considerable effort that the two roots of the quadratic equation are less than one in absolute value if and only if

$$\Delta x < \frac{2\,|ur|\,\Delta\Phi}{|w|\left(1+\frac{1}{\gamma}\right)+\sqrt{\left(1-\frac{1}{\gamma}\right)^2 w^2+\frac{4h}{\gamma M_\infty^2}}} \tag{25}$$

The results as represented by Eqs. (24), (25) apply to the simplified linear system Eq. (21). It has been found numerically that the restriction for the actual nonlinear system of equations [Eqs. (7) through (20)] is qualitatively like Eqs. (24), (25). Quantitatively the restriction is similar to Eq. (24).

Once the solution can be obtained at x_{j+1}, the question of whether the scheme is stable for marching in the x direction must be answered. To analyze the stability, the following system is considered.

$$\begin{aligned}
&\frac{\partial u}{\partial x}+\frac{1}{\rho u}\frac{\partial p}{\partial x}-Re^*\left(\frac{\partial^2 u}{\partial\Phi^2}+r^2\frac{\partial^2 u}{\partial y^2}\right)=0\\
&\frac{\partial v}{\partial x}-Re^*\left(\frac{\partial^2 v}{\partial\Phi^2}+r^2\frac{\partial^2 v}{\partial y^2}\right)=0\\
&\frac{\partial w}{\partial x}-Re^*\left(\frac{\partial^2 w}{\partial\Phi^2}+r^2\frac{\partial^2 w}{\partial y^2}\right)=0\\
&\frac{\partial p}{\partial x}+\frac{p}{u}\frac{\partial u}{\partial x}-\frac{p}{h}\frac{\partial h}{\partial x}=0\\
&\frac{\partial h}{\partial x}-\frac{\gamma-1}{\gamma}\frac{h}{p}\frac{\partial p}{\partial x}-Re^*\left(\frac{\partial^2 h}{\partial\Phi^2}+r^2\frac{\partial^2 h}{\partial y^2}\right)=0
\end{aligned} \tag{26}$$

The above equations are differenced implicitly and the resulting equations are studied using the Fourier series technique. The equations are stable if the eigenvalues of the amplification matrix are less than or equal to one in absolute value. The second and third equations are uncoupled from the system. It can easily be shown that they are unconditionally stable.

For the remaining three equations one of the eigenvalues is $\lambda = 1$, and another is

$$\lambda = \frac{1}{1 - 2\,Re^{*}\left[(\cos m_1\Delta\Phi - 1)\,\frac{\Delta x}{\Delta\Phi^2} + (\cos m_2\Delta y - 1)\,\frac{r^2\Delta x}{\Delta y^2}\right]} \tag{27}$$

which is less than or equal to one in absolute value.

Since the first four eigenvalues are less than or equal to one in absolute value, the stability of the system of Eq. (26) depends on the magnitude of the fifth and final one. Three different cases are considered depending on how the $\partial p/\partial x$ term in the x-momentum and energy equations is differenced. In the first case, if $\partial p/\partial x$ is set to zero as suggested by Rubin and Lin (Ref. 14), then the fifth eigenvalue is the same as Eq. (27). Thus, the difference equations are unconditionally stable as a marching scheme in x.

The second case corresponds to evaluating $\partial p/\partial x$ backwards in x [Eq. (23)], as suggested by Ohrenberger and Baum (Ref. 13). If $M_x \geqq 1$ then it can be shown that the magnitude of the eigenvalue is less than or equal to one. However, if $M_x < 1$, which occurs near the cone due to the boundary condition $u = 0$, the following restriction must be satisfied to ensure that the absolute value of the eigenvalue is less than or equal to one.

$$\Delta x \geqq \left(\frac{1}{M_x^2} - 1\right)\frac{1}{2\gamma Re^{*}}\left[\frac{1}{(1-\cos m_1\Delta\Phi)\,\frac{1}{\Delta\Phi^2} + (1-\cos m_2\Delta y)\,\frac{r^2}{\Delta y^2}}\right] \tag{28}$$

The third case corresponds to taking $\partial p/\partial x$ implicitly. For this case it is found that Δx must be twice as big as for the previous case where $\partial p/\partial x$ was evaluated explicitly. This implies that if a different method were used to solve the implicit equations (the proposed Newton-Gauss-Seidel method does not converge when $\partial p/\partial x$ is differenced implicitly as mentioned previously) a numerical solution to the fluid flow equations could be obtained if Δx were chosen sufficiently large. A lower bound restriction on the marching step-size has also been found for certain stiff ordinary differential equations by Curtiss and Hirschfelder (Ref. 15) in order to suppress so called departure solutions. The case here is analogous to the ordinary differential equation case. The departure is characterized by the leeward surface pressure oscillating or rapidly increasing, and has been observed by Baum and Denison (Ref. 12), Rubin and Lin (Ref. 14), and Tyson (Ref. 16). Tyson experimentally found that a large stepsize was necessary to suppress the departure solutions.

SECTION IV

NUMERICAL RESULTS

To demonstrate the validity of the technique, solutions have been compared with experimental data obtained by Tracy (Ref. 8) on a sharp 10 deg half angle cone at an angle of attack of 12 deg. The parameters used in the calculation are given in Table I. These correspond closely to the experimental data. Initial conditions, which would normally come from a solution to the nose region, are needed before an exact comparison can be obtained. Since the nose solution was not available, the following technique was used to generate the required initial conditions. Starting at zero, the angle of attack was slowly increased while marching along the cone until 12 deg was reached at an $x = x_o$. The calculations are then continued at a constant 12 deg angle of attack, and the solution is allowed to relax to the desired sharp cone results. Because of the method used to generate the initial conditions, the calculations are not expected to agree with the data at the same x station. However, the calculation should relax to results which are similar to the data (except the difference in local Reynolds number) as the solution continues downstream.

Table I. Parameters for Tracy's Case

Parameter	Symbol and Value
cone half angle	$\theta = 10$ deg
angle of attack	$\alpha = 12$ deg
freestream Mach number	$M_\infty = 8$
freestream Reynolds number	$Re = 1.1 \times 10^6$/ft
freestream Prandtl number	$Pr = 0.75$
ratio of specific heats	$\gamma = 1.4$
Sutherland constant	$S = 2$
freestream dimensionless pressure	$p_\infty = 0.0112$
static enthalpy at the cone	$h_w = 5.5$

Preceding page blank

Figures 2, 3 show the experimental surface pressure and heat transfer around the cone at $x = 0.33$ ft and the calculated results at $\bar{x} \equiv x/x_o = 8.5$, 25, and 50. The calculated heat transfer results illustrate that at $\bar{x} = 8.5$ the effect of the initial conditions at $x = x_o$ have not yet relaxed. At $x = 25$ and 50 the calculations appear to be approaching a relaxed result and the agreement with the heat transfer data is very good.

In Figure 4, a comparison between the measured and calculated bow shock and viscous layer thickness around the cone is given. The data were taken at $x = 0.286$ ft, the calculated results at $\bar{x} = 50$ are shown. Finally in Figure 5, the calculated velocity vectors on the leeward side projected normal to the streamwise direction are shown. The separated flow region on the leeward side is clearly shown by this figure.

The above results were obtained by evaluating $\partial p/\partial x$ explicitly. Runs were also made with $\partial p/\partial x = 0$ and the results differed very slightly from those presented.

A comparison of actual convergence and stability restrictions with the analytical restrictions for this case is presented in Figure 6. From Eq. (24) with $\Delta\Phi = 10$ deg and taking 1 as a lower bound for $|u/w|$ we see that

$$\frac{\Delta x}{x} < 0.03 \tag{29}$$

is necessary for convergence. Equation (28) implies that the biggest restriction occurs for small u, that is near to the cone. To simplify the expression, suppose that $\cos m_1\Delta\Phi$ and $\cos m_2\Delta y$ are zero. This is not strictly valid; however, we are looking for an approximate answer. Making this assumption may not give us precise quantitative results but hopefully qualitative results will be obtained. For the cases run, $\Delta y << r\Delta\Phi$. The nearest point to the cone that is solved for corresponds to $y = \Delta y$. The functions p and μ evaluated at Δy are approximately constant as functions of x. Also it

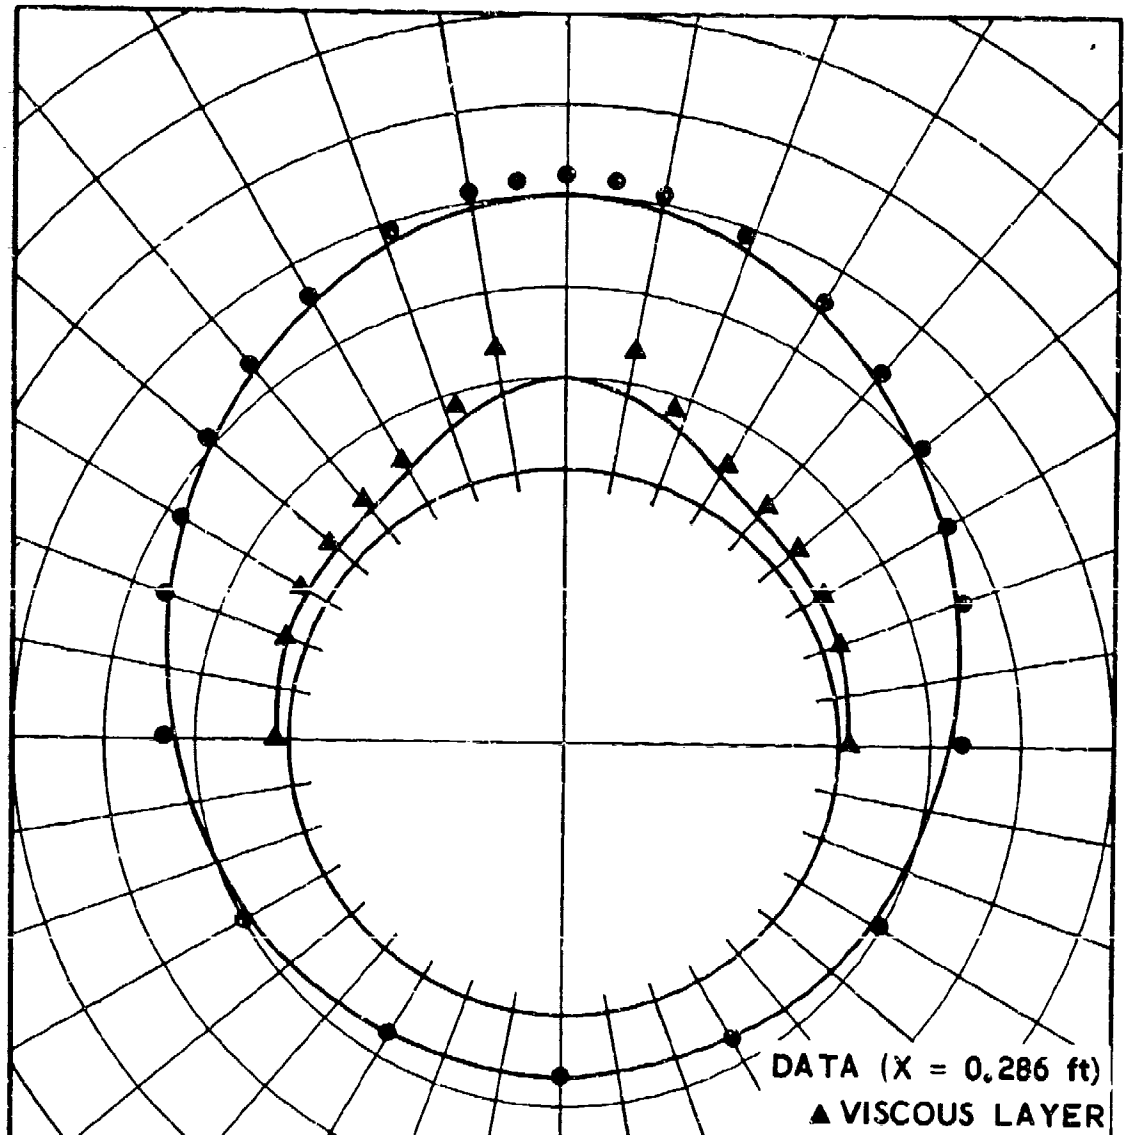

Figure 2. Geometry of the Flow for Tracy's Case, α = 12 deg

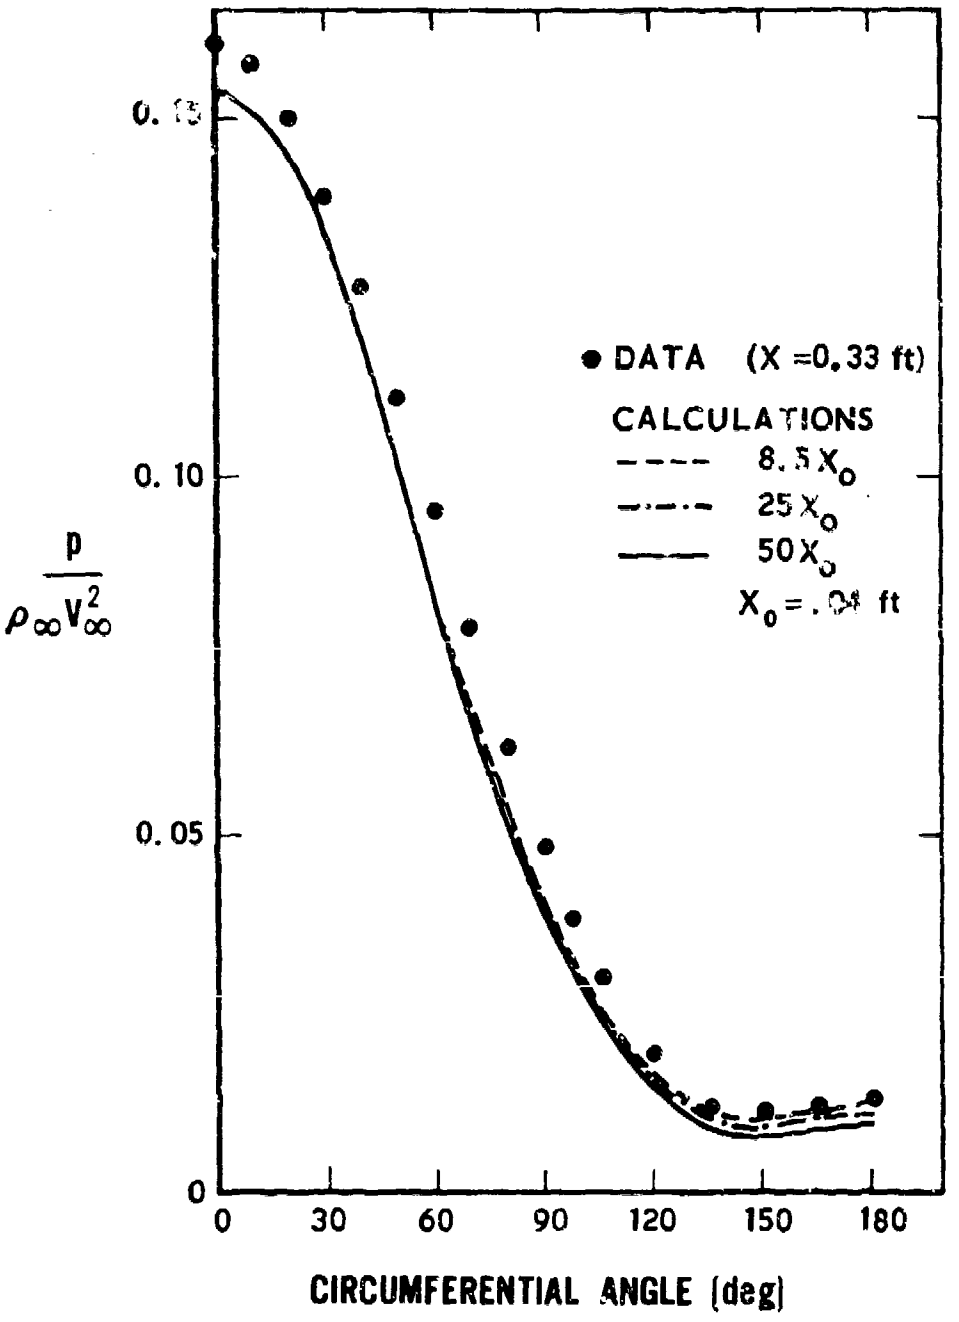

Figure 3. Circumferential Surface Pressure Distribution for Tracy's Case, α = 12 deg

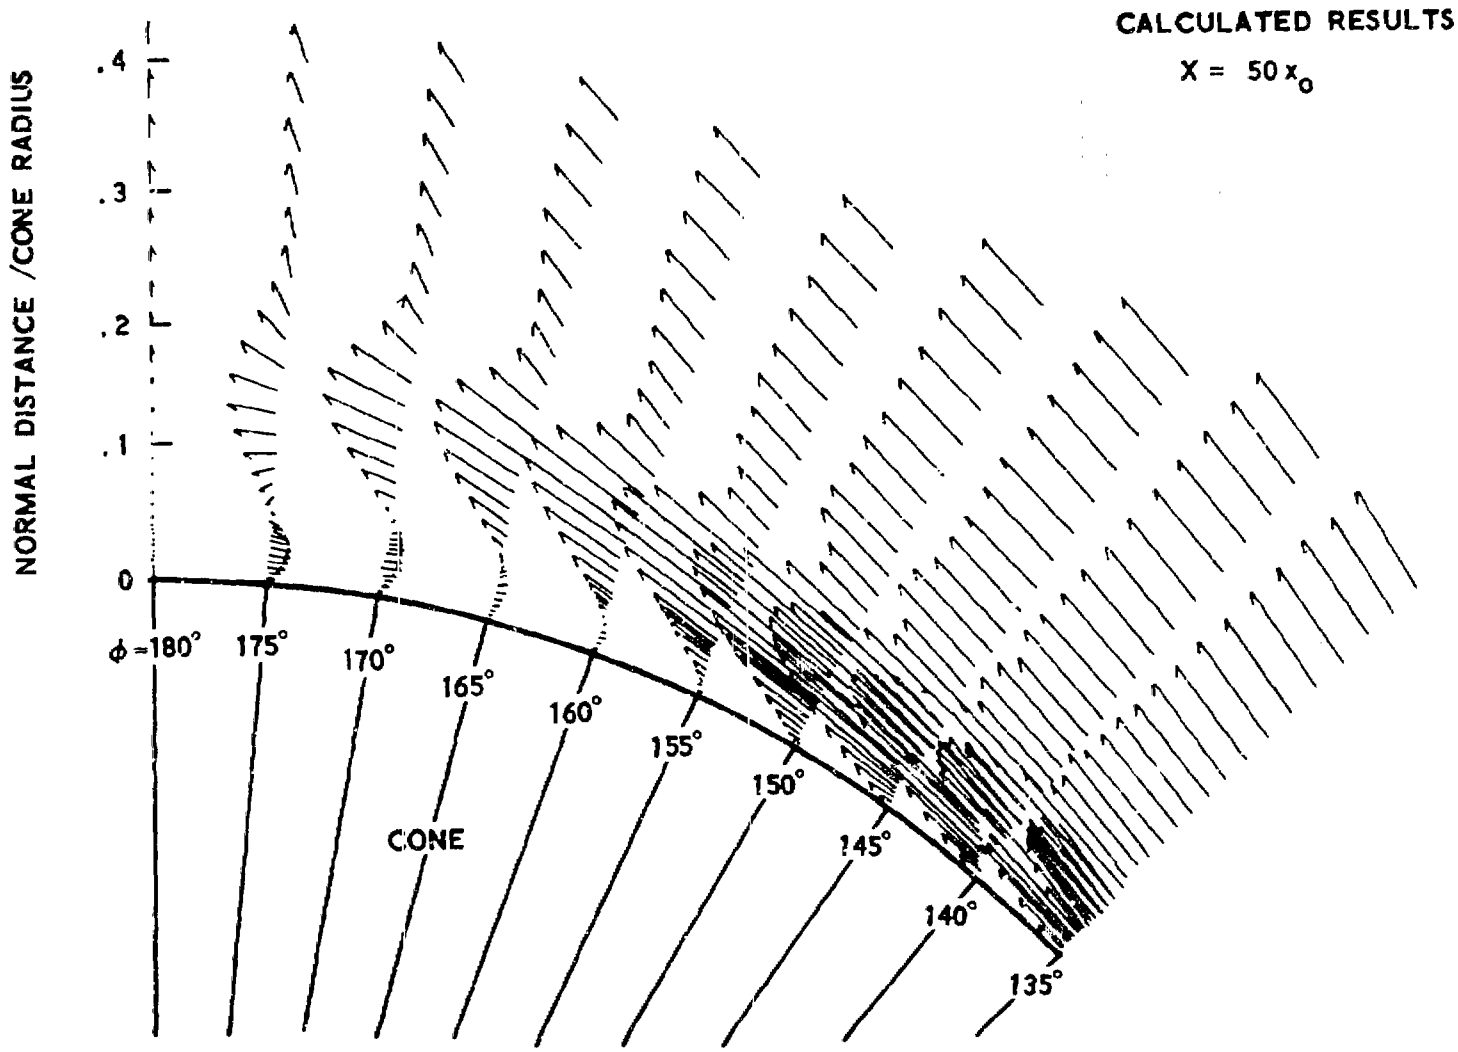

Figure 5. y - Φ Velocity Vector Distribution for Tracy's Case, α = 12 deg

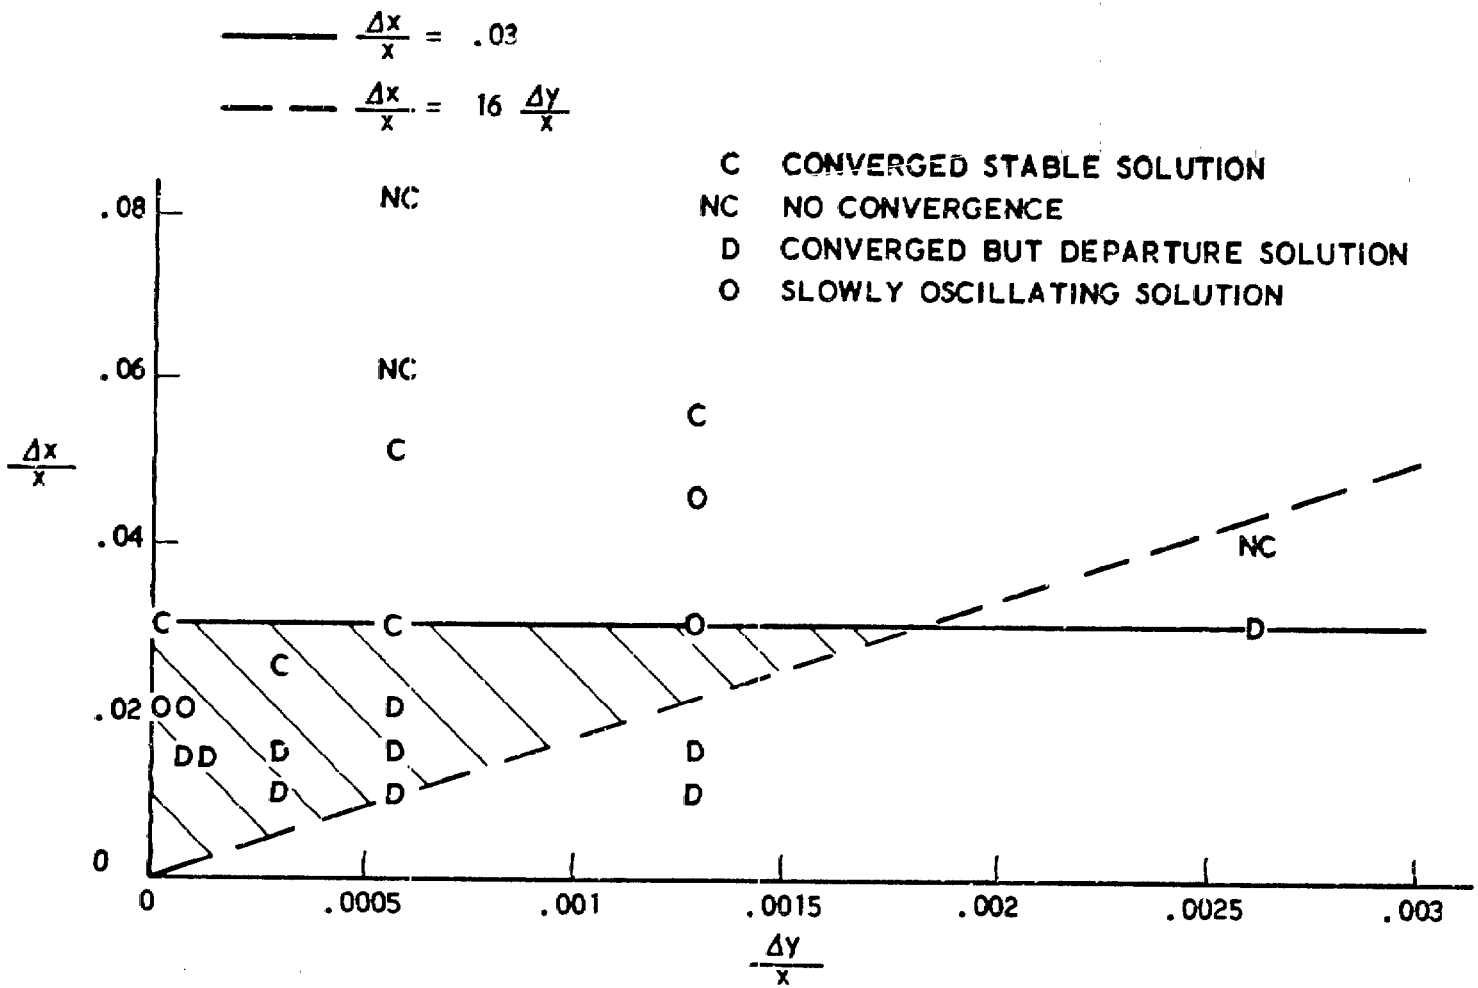

Figure 6. Comparison of Analytical and Numerical Results

has been observed that the ratio $\Delta y/u$ where u is evaluated at $y = \Delta y$ is almost constant as a function of x. Thus Eq. (28) is approximately

$$\frac{\Delta x}{x} = \left[\frac{Rep}{2\mu} \Delta y\right] \frac{\Delta y}{x} \tag{30}$$

where the expression in brackets in Eq. (30) is approximately constant. In addition, since the transformation $y = \eta\xi$ is made, $\Delta y = \Delta\eta\xi$; and since ξ increases approximately linearly with x, then $\Delta y/x$ remains constant as x increases. Equation (30) then implies that for an initially chosen Δy, Δx must increase linearly as x increases. Therefore if Δy is chosen so that Eqs. (30), (29) are satisfied initially, they will be satisfied for all x provided Δx increases proportionally to x.

Tracy's case was run with $\Delta x/x = 0.03$ and a $\Delta\eta$ spacing such that initially $\Delta y/x = 0.0006$. The expression in brackets in Eq. (30) is equal to 16 so that Eq. (30) is satisfied. With $\Delta\Phi = 10$ several different values for Δx and Δy were used to determine how accurate the derived inequalities are. The results are shown in Figure 6. The shaded region is the predicted area where convergent stable solutions should be obtained. The actual region of convergent stable solutions is somewhat different. However, the qualitative results are correct. It was found that increasing Δx slowed down the convergence of the iterative procedure to obtain the solution at an x station until finally it did not converge. Decreasing Δx sped up the convergence but produced solutions that departed as a function of x. Increasing Δy led to departure solution and decreasing Δy led to stable solutions. For a few cases the results for the surface pressure on the leeward side (the most critical for departure) at $\alpha = 12$ deg are shown in Figure 7.

A second case has been run to compare with experimental data obtained by Stetson and Ojdana (Ref. 9) on a sharp 5.6 deg half angle cone at an angle of attack of 8 deg. The parameters used in the calculation are given in Table II. Figure 8 shows the wall pressure distribution on the leeward side at $\bar{x} = 17$. Stetson's case was run with $\partial p/\partial x = 0$. Analysis of the restrictions

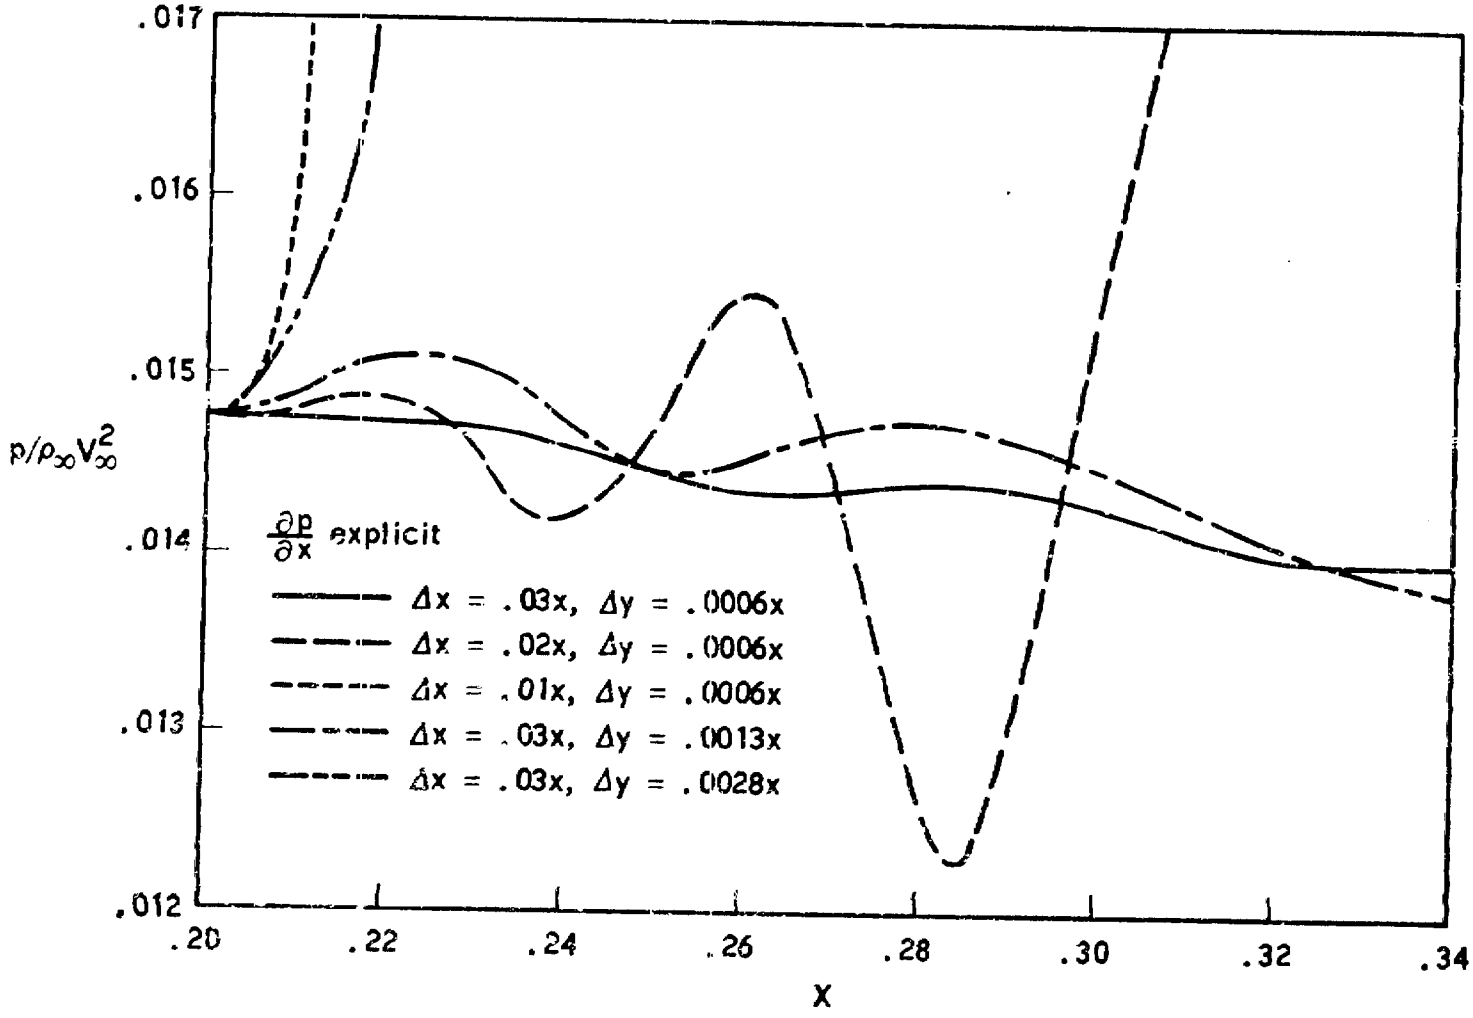

Figure 7. Leeward Surface Pressure for Different Values of Δx and Δy

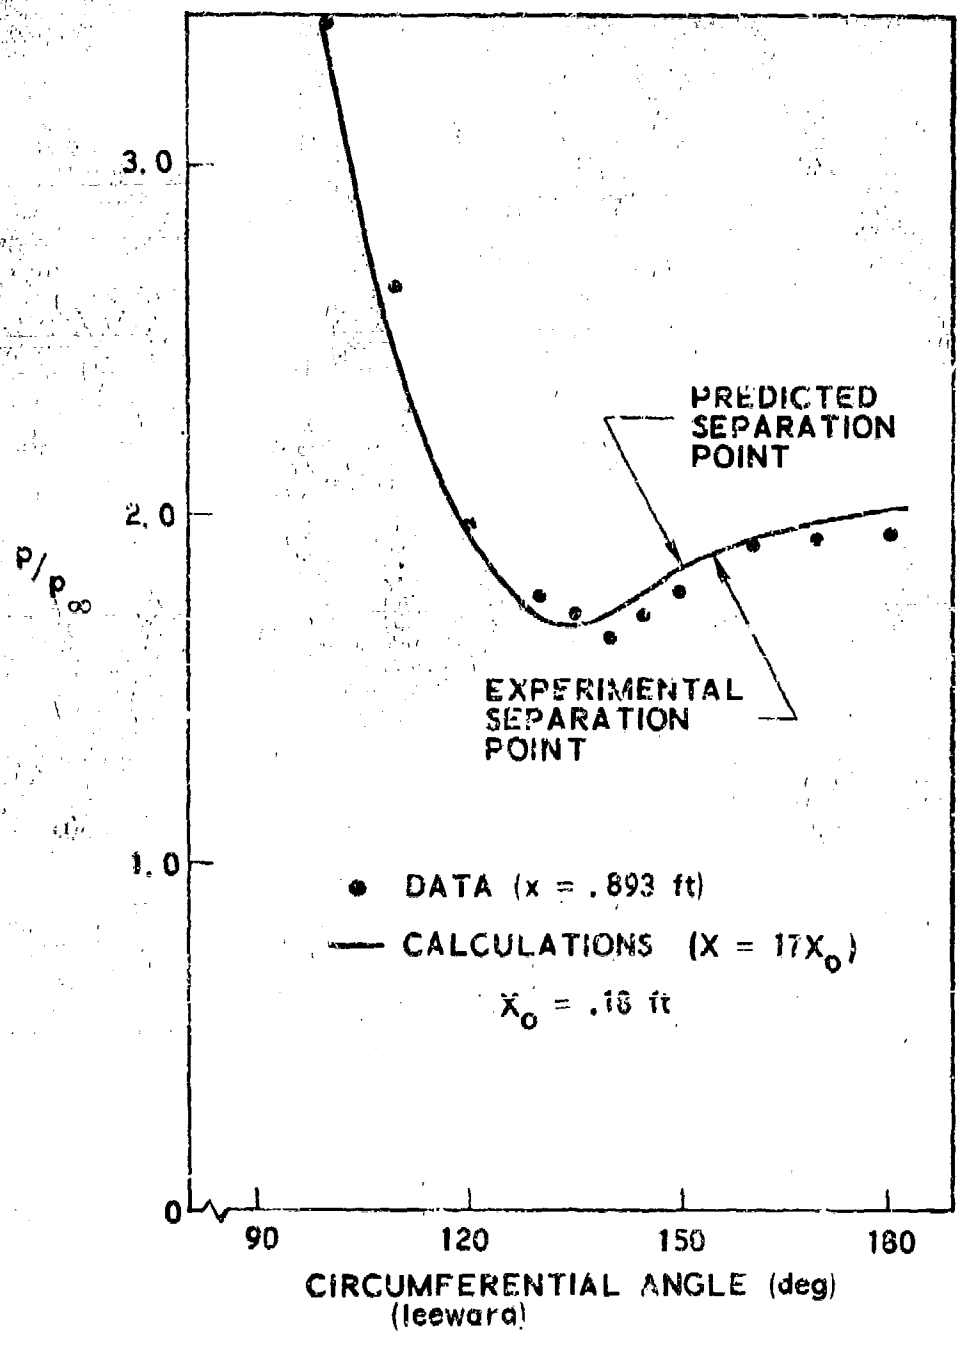

Figure 8. Circumferential Surface Pressure Distribution for Stetson's Case, α = 8 deg

on Δx for $\partial p/\partial x$ evaluated explicitly as was done for Tracy's case led to Δx spacings that were much too small in the sense that too many y mesh points were required and the storage capability of the computer was exceeded. Numerical experimentation verified that the solution could not be obtained for any permissable mesh spacing when $\partial p/\partial x$ was evaluated explicitly.

Table II. Parameters for Stetson's Case

Parameter	Symbol and Value
cone half angle	$\theta = 5.6$ deg
angle of attack	$\alpha = 8$ deg
freestream Mach number	$M_\infty = 14.2$
freestream Reynolds number	$Re = 0.83 \times 10^6$/ft
freestream Prandtl number	$Pr = 0.75$
ratio of specific heats	$\gamma = 1.4$
Sutherland constant	$S = 4$
freestream dimensionless pressure	$p_\infty = 0.00354$
static enthalpy at the cone	$h_w = 32.398$

SECTION V

COMPUTER PROGRAM

A computer program has been developed for the CDC/7600 computer that solves the above equations. Provision has been made for variable grid sizes in both the y and Φ directions and this feature has been used heavily. The iteration logic has been structured so that when the solution along a Φ line converges to the desired number of figures, that line is dropped from the iteration loop. This saves considerable time since a few Φ lines require as many as seven iterations to converge to five figures while most Φ lines require only two or three iterations.

For 50 points in the y direction and 23 points in the Φ direction the program requires 35,000 words of storage. It takes 30 sec to obtain the solution accurate to five figures at one x station. Eleven percent of this time is spent evaluating all the derivative expressions, 33 percent is spent computing the Jacobian coefficient matrix, and 56 percent is spent solving the linear equations. For Tracy's case it took about 120 steps to go from $\bar{x} = 1$ to $\bar{x} = 50$.

For convenience in programming the derivatives were defined as

$$\frac{\partial u^n}{\partial \Phi} = \left(u^n_{j+1,k,\ell+1} - u^{n+1}_{j+1,k,\ell-1}\right) \Big/ 2\Delta\Phi$$

$$\frac{\partial^2 u^n}{\partial \Phi^2} = \left(u^n_{j+1,k,\ell+1} - 2u^{n+1}_{j,k,\ell} + u^{n+1}_{j,k,\ell-1}\right) \Big/ \Delta\Phi^2$$

The right hand side of Eq. (4) became

$$-\frac{\partial u^n}{\partial x} - a\frac{\partial u^n}{\partial \eta} - b\frac{\partial u^n}{\partial \Phi} + c\frac{\partial^2 u^n}{\partial \eta^2} + d\frac{\partial^2 u^n}{\partial \Phi^2}$$

Preceding page blank

where the underlined terms in Eq. (4) have been ignored. It is seen that it is necessary to store only two planes of the solution, one at j and one for the current iterate at j+1. The n+1 iterate is stored on top of the n iterate as it is computed.

SECTION VI

DISCUSSION AND CONCLUSIONS

A method for solving the implicit difference equations describing the three-dimensional flow around a cone at angle of attack has been described and analyzed. These equations which are derived and discussed in Ref. 6 constitute a system of three-dimensional nonlinear parabolic equations. The technique for solving these equations has been shown to be accurate and efficient in both running time and computer storage.

The numerical method is not restricted to steady flow problems but could easily be applied to two-dimensional time dependent calculations.

An analysis of the numerical aspect of departure solutions has been presented. Methods that have been proposed by other authors to suppress the departure solutions have been verified and in some cases qualified. In addition, it has been shown that departure solutions can be suppressed even if the streamwise pressure derivative is included, if the steps ze is large enough.

Results have been compared with experimental data and the agreement is very good.

NK	=	number of y-stations at which initial conditions are specified
NL	=	number of Φ-stations at which initial conditions are specified
MØD	=	.TRUE. or .FALSE. depending on whether the input mesh distribution is to be modified or not. Default is .FALSE.
ITAPE	=	0, no output on TAPE2, this is the default
	=	N, output solution on TAPE2 every Nth x-step

The rest of the input is read using format control.

IREAD (I12)

IREAD > 0 read initial profile from TAPE3, used for restart purposes. The first profile on TAPE 3 at an x station bigger than or equal to X(1) is selected as the initial profile.

IREAD ≤ 0 read initial profile from cards

If IREAD ≤ 0 then the cards with the solution are input

repeat NL times:

FI(L), ZI(1, L) (2E12.5)

FI(L) is a Φ station in degrees

ZI(1, L) is the shock distance at Φ

ET(K), U(K, L), V(K, L), W(K, L), P(K, L), H(K, L), K=1, NK(6E12.5)

ET(K) is a distance from the body (=y not y/shock)

U, V, W, P, H are values of u, v, w, p, h at ET(K), FI(L)

X(J) J=1 or J=1, NJ (6E12.5)

X(J) is an X-station along the body. If J=1 then the rest of the points are obtained using X(J+1) = c * X(J) where c is a constant > 1. X(1) is the position of the initial profile.

The following cards describe v and h at the body:

L (I12)

L is the index of a Φ station

J, VB(J, L), HB(J, L) (I12, 2E12.5)

J is the index of an X station

VB(J, L) is the value of v at the body at X(J), FI(L)

HB(J, L) is the value of h at the body at X(J), FI(L)

This card is repeated with N increasing from 1 to NJ.

If any J stations are skipped then linear interpolation is used to obtain VB and HB at the skipped stations

There then follows a card with another L value and cards with J, VB, and HB. These groups are repeated with L increasing from 1 to NL. If any L stations are skipped then linear interpolation is used to obtain VB and HB at the skipped stations.

If MOD=.TRUE. more cards are needed.

NEWK, NEWL (2I5)

NEWK is a new value for NK, and indicates that the input η distribution is to be changed. If the η distribution is not to be changed then leave NEWK blank.

NEWL as with NEWK but for NL and Φ.

If NEWK > 0

ETNEW(K) K=1, NEWK (6D12.4).

The numbers must increase from 0. The input numbers are scaled by the program to go from 0. to 1. by dividing by ETNEW (NEWK)

If NEWL > 0

FINEW(L) L=1, NEWL (6D12.4)

These are the new Φ stations in degrees. They must increase from 0 to 180 deg.

APPENDIX B

PROGRAM OUTPUT

The namelist input is printed out. If the initial profiles were read from cards then the card images are printed.

The x-stations at which the solution will be obtained are printed.

The input profiles are printed and if the mesh distribution was changed, then the new initial profiles are printed.

The profiles are printed at each x-station as they are obtained. Preceeding each station printout is printed the iteration and convergence history for that x-station. The variables printed are ITER and INS(L), L=1, NL. If all Φ-rays have converged then ITER=0, otherwise ITER=1. If the Lth Φ-ray has converged then INS(L) = 0, otherwise INS(L) = 1.

The parameters read in with namelist are written on TAPE4, followed by the profiles at each x-station. The data are written without format control and can be used to supply initial conditions.

If ITAPE > 0 then the profiles are written on TAPE2 at each ITAPEth x-station. TAPE2 can be set up as the punch file.

APPENDIX C

EXAMPLE PROBLEM

The input necessary to run Tracy's case (see Table I) is given in Appendix D. The sequence numbers on the initial condition profiles are not required, they are included on the sample deck to aid in ordering the cards if they get mixed up.

The output from the program is presented in Appendix E. The solution has been printed at only a few mesh points.

After running much further along the cone the solution profiles obtained would be similar to those shown in Figures C-1, C-2, C-3, C-4, and C-5.

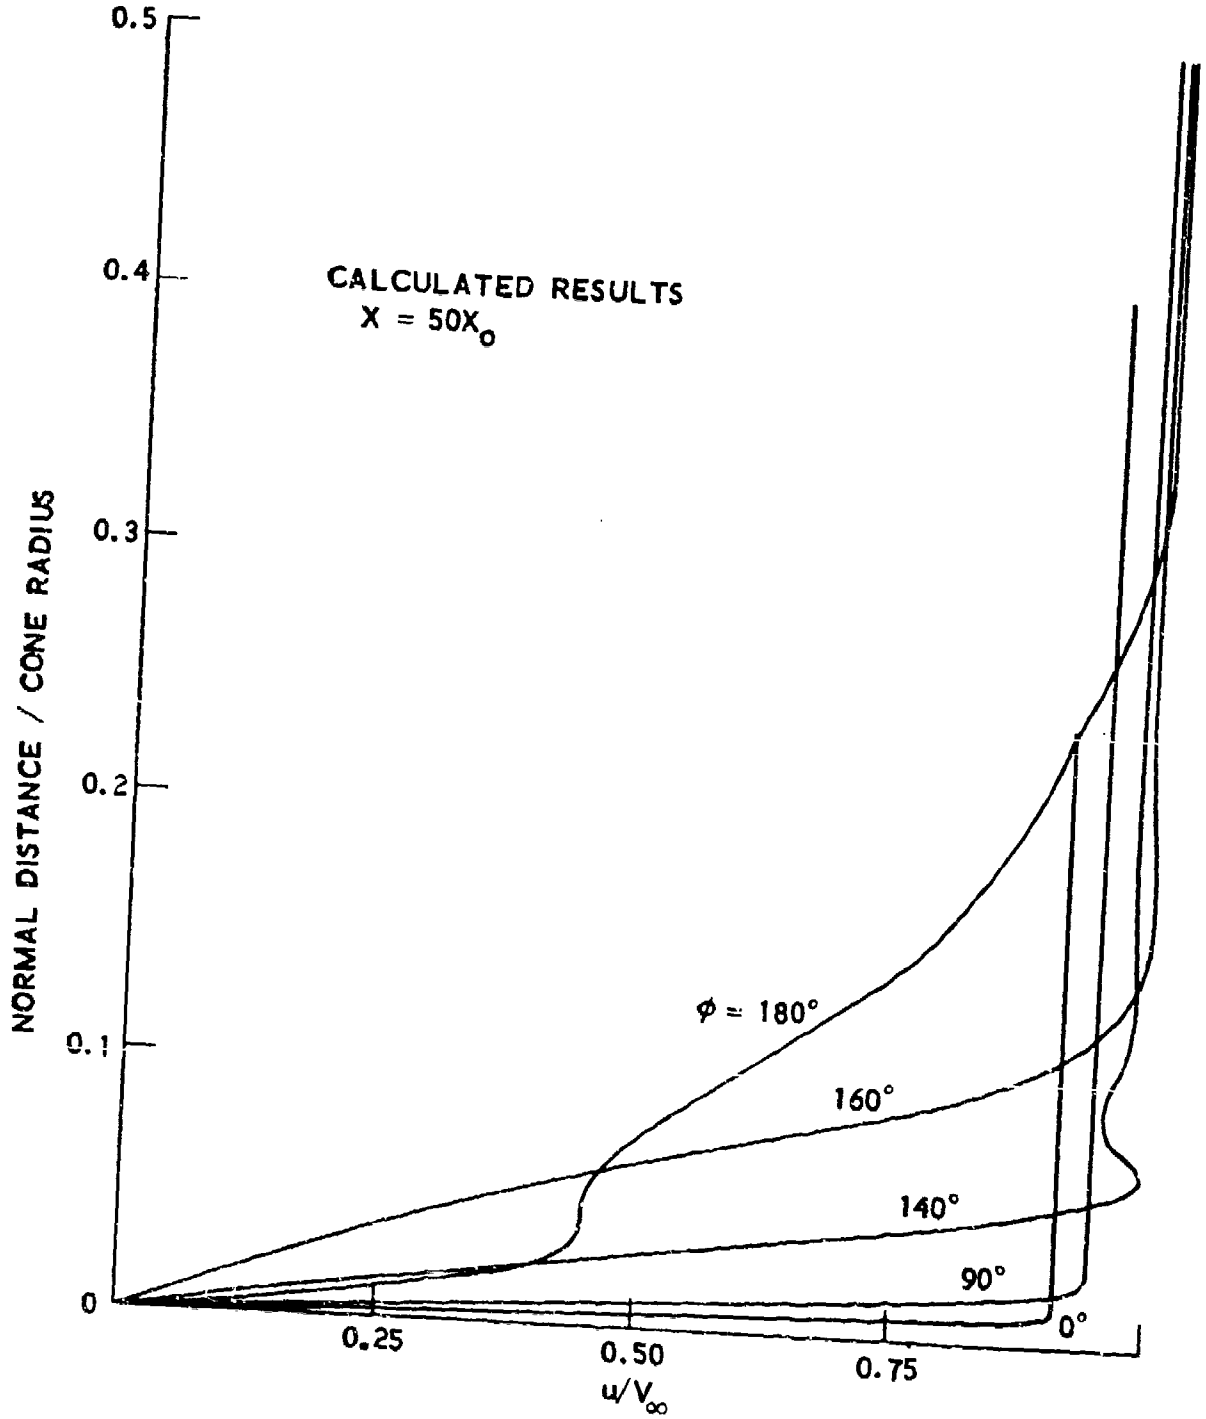

Figure C-1. Streamwise Velocity Profiles for Tracy's Case, α = 12 deg

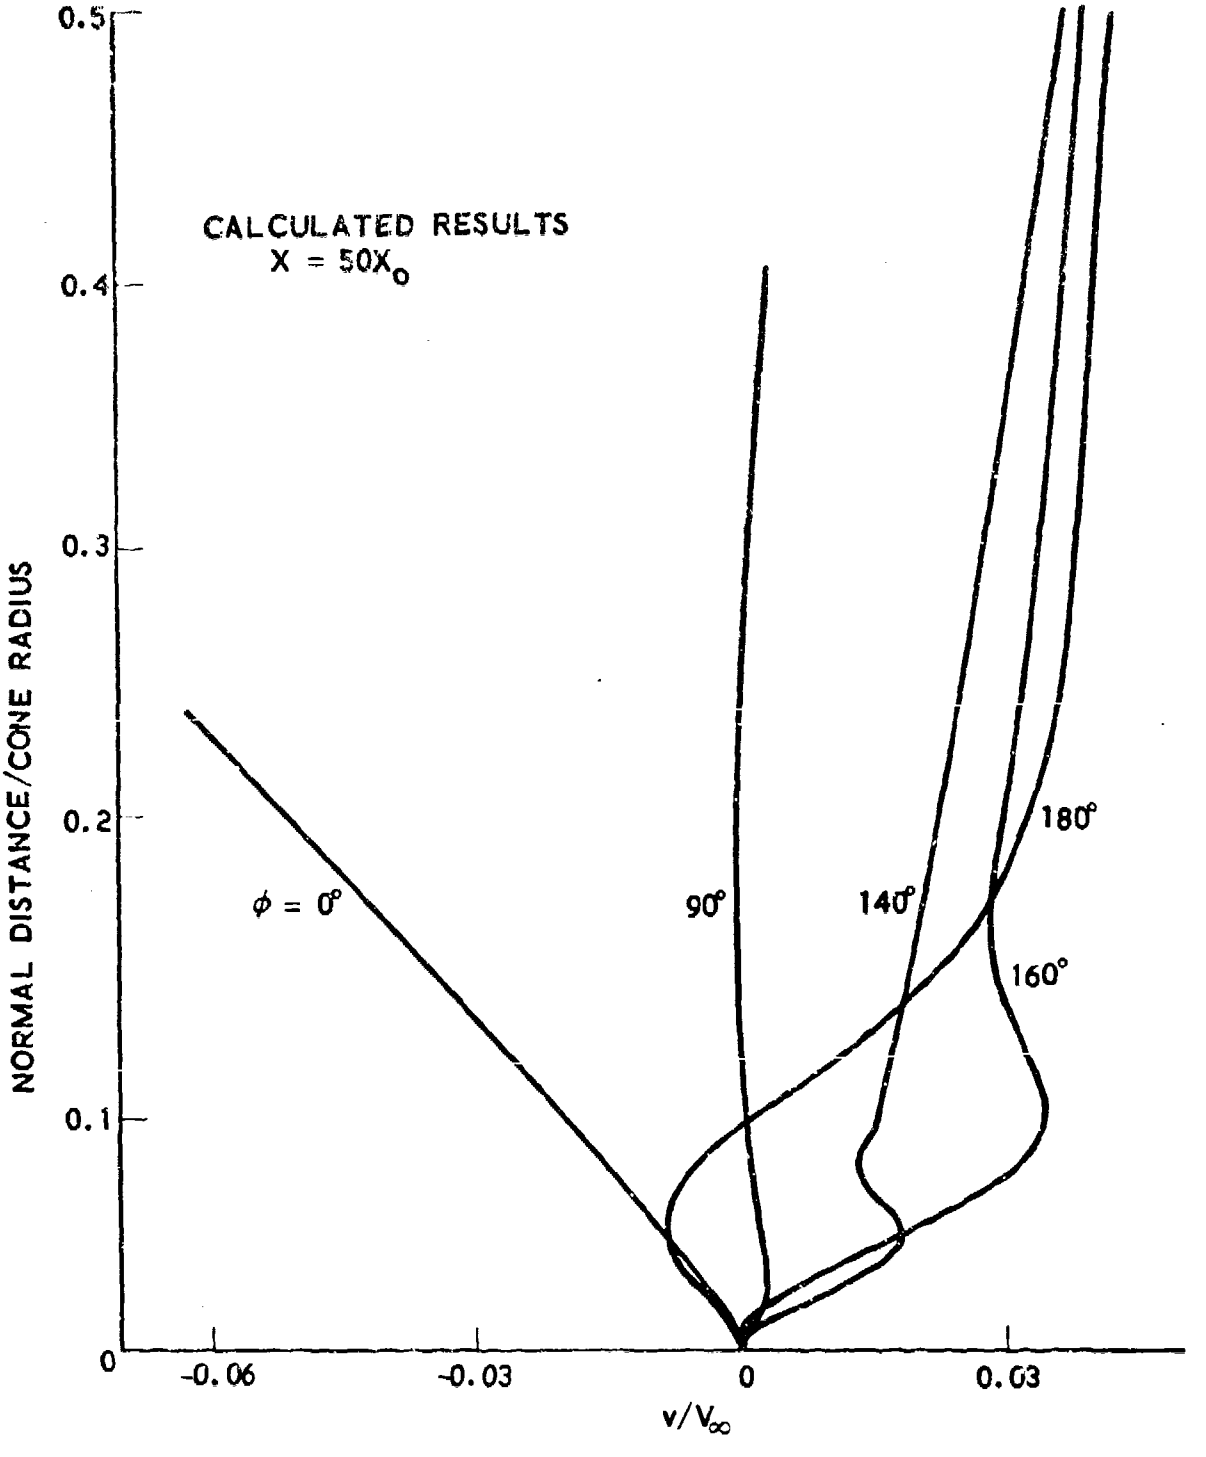

Figure C-2. Normal Velocity Profiles for Tracy's Case, α = 12 deg

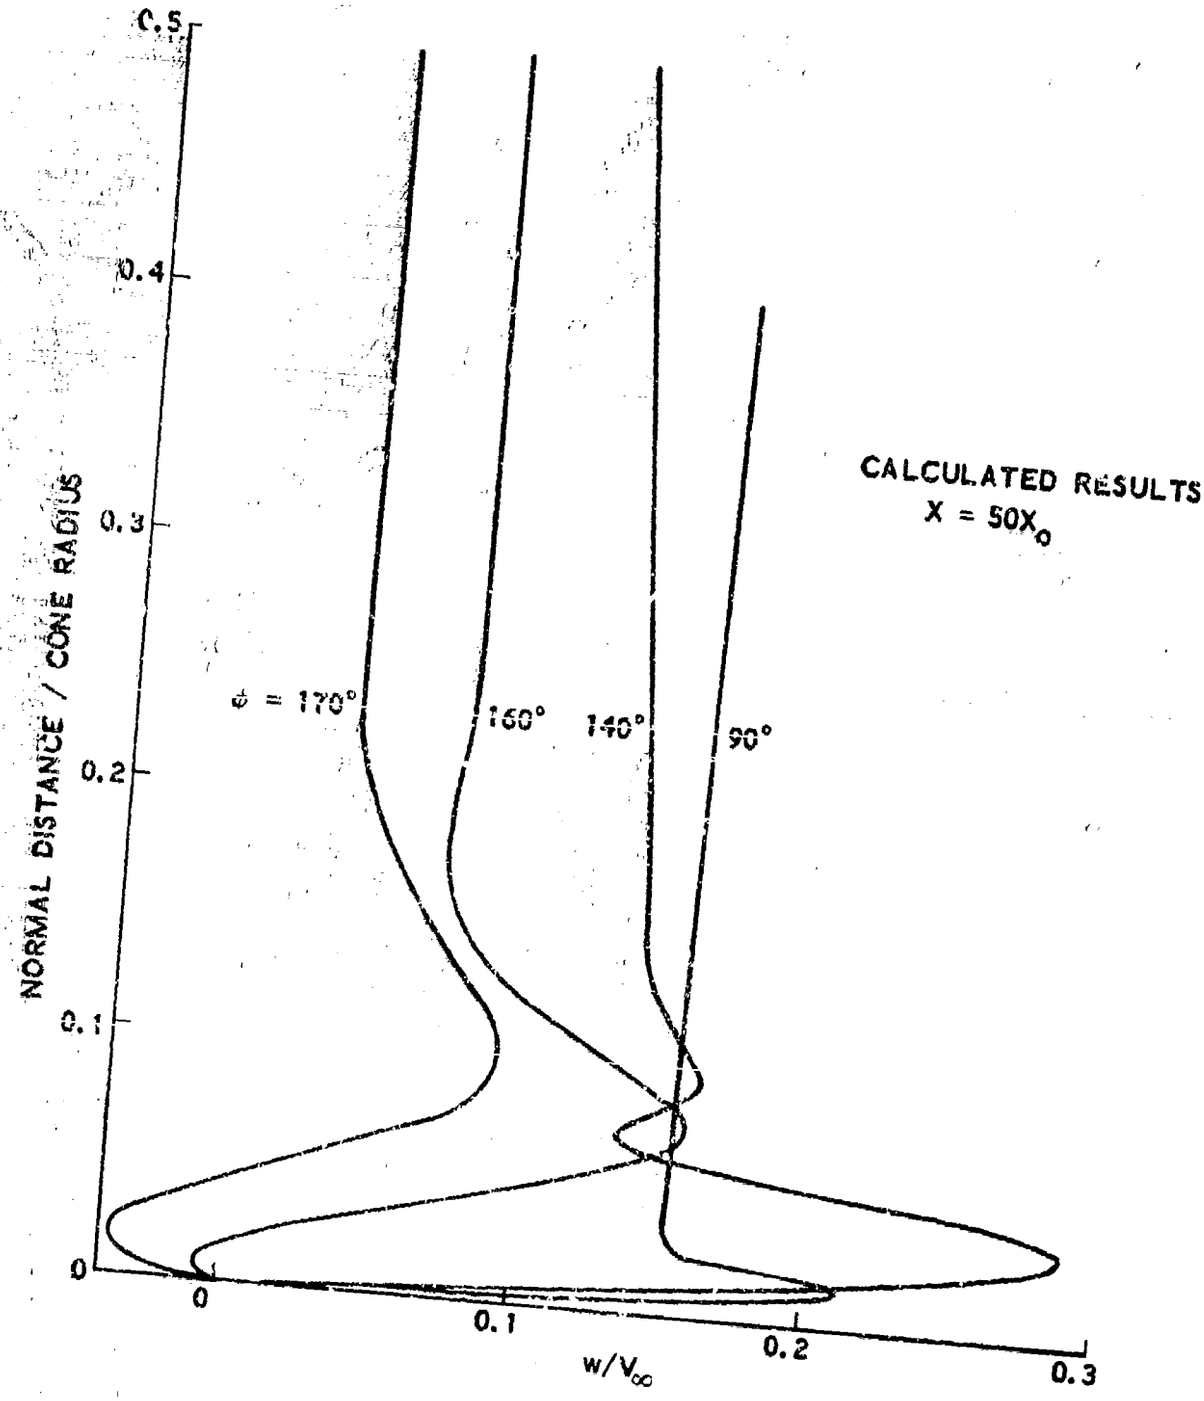

Figure C-3. Circumferential Velocity Profiles for Tracy's Case, α = 12 deg

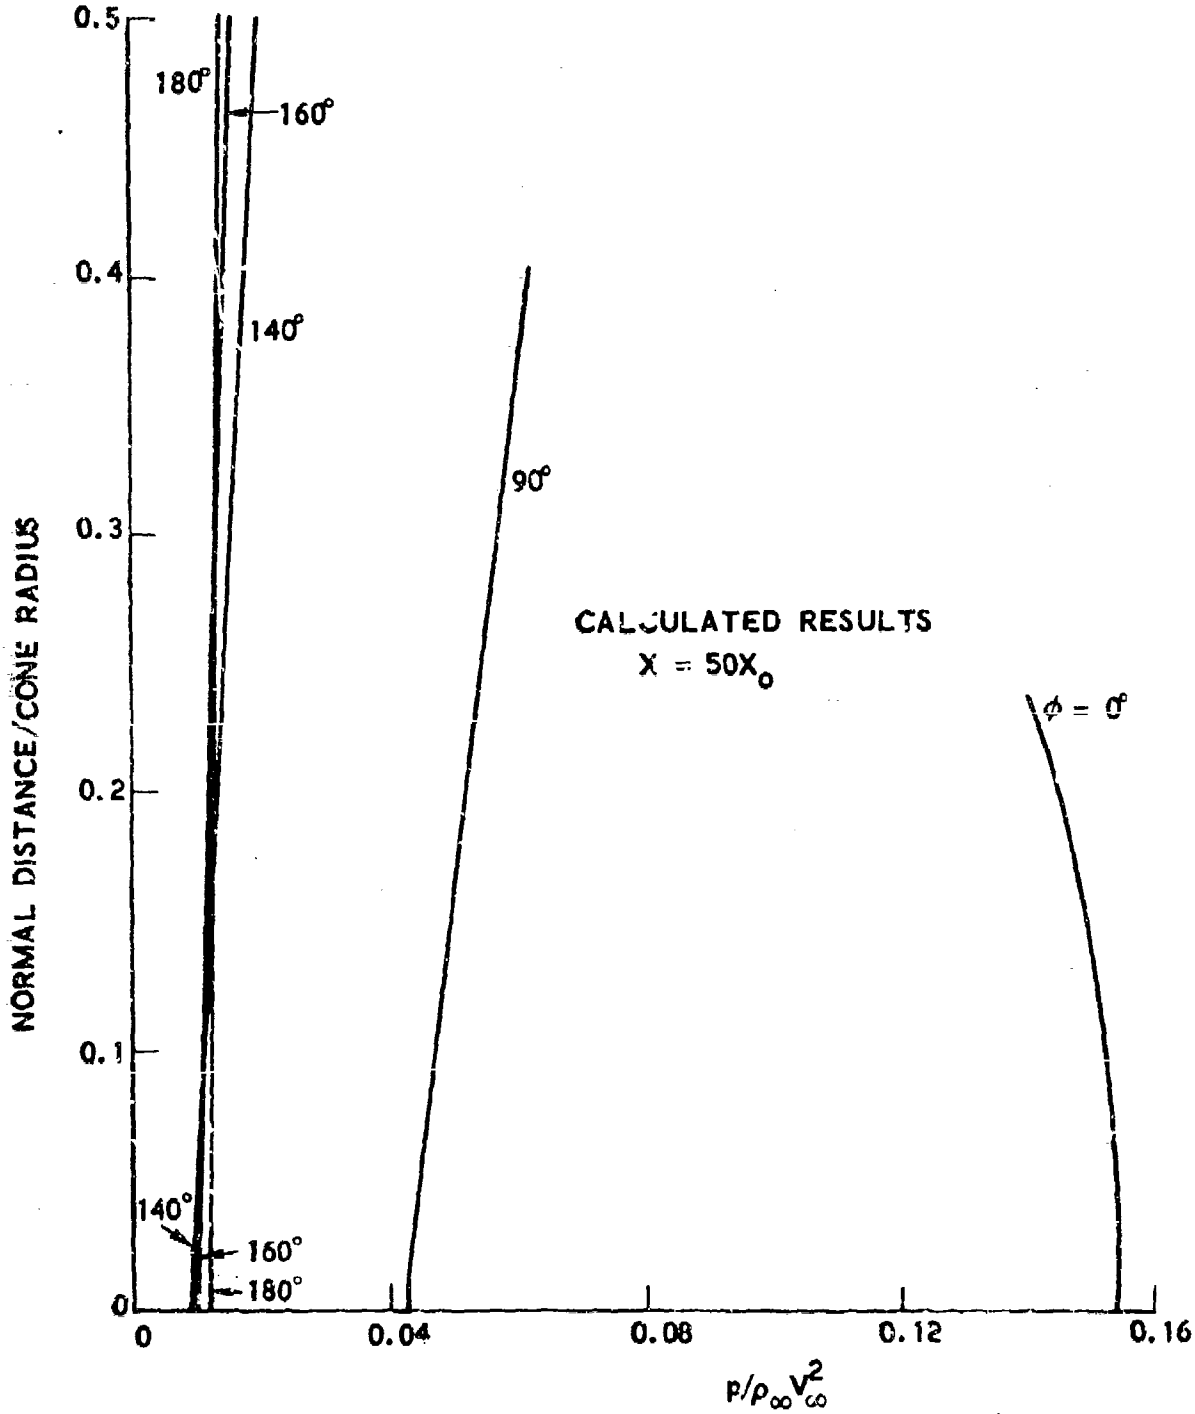

Figure C-4. Pressure Profiles for Tracy's Case. α = 12 deg

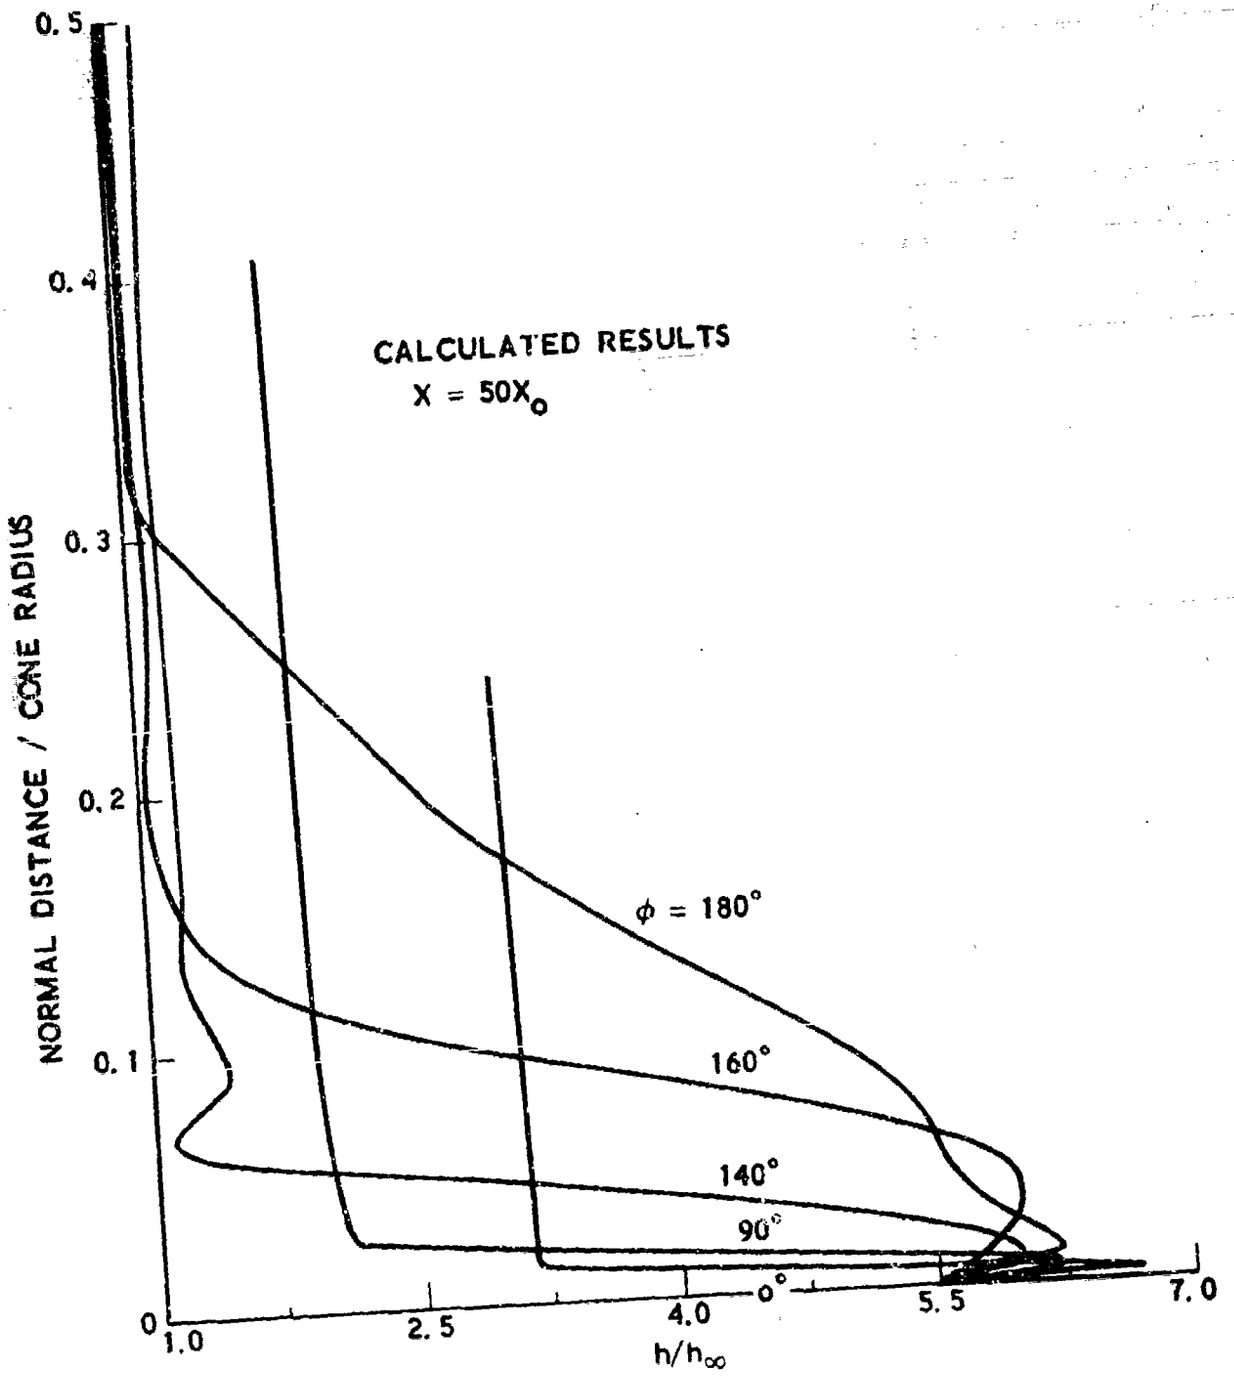

Figure C-5. Enthalpy Profiles for Tracy's Case, α = 12 deg

APPENDIX F

PROGRAM LISTING

```
      PROGRAM  AOFA(INPUT,OUTPUT,              TAPE5=INPUT,TAPE6=OUTPUT,
     &                TAPE2,TAPE3,TAPE4)
C          THIS IS THE MAIN ROUTINE.
C          THE MAXIMUM SIZE OF ALL ARRAYS IS SPECIFIED IN THE
C          DIMENSION STATEMENT.  IF MAXJ,MAXK,MAXL DENOTE THE
C          UPPER BOUNDS FOR J,K,L, AND MAXKL DENOTES THE LARGER
C          OF MAXK AND MAXL THEN THE ARRAYS ARE DIMENSIONED
C          DEPVAR(MAXK*MAXL,18)
C          ABCFD(MAXKL,120)
C          ET(MAXK),FI(MAXL),X(MAXJ)
C          INETFI(MAXL),INFIET(MAXK)
C          VB(MAXJ,MAXL),HB(MAXJ,MAXL)
C          COEFF(MAXJ,MAXL),DEL((MAXK-1)*6),RISIDE((MAXK-1)*6),
C          WORK1(1,1),WORK2(1),WORK3(1),WORK4(1).
C          IF MAXK IS GREATER THAN 108 THEN THE DIMENSION OF Y IN
C          BLANK COMMON SHOULD BE MAXK.
C
C
C          TAPE2 IS AN OUTPUT UNIT, SEE SUBROUTINE OUTPUT.
C          TAPE3 AND TAPE4 ARE INPUT AND OUTPUT UNITS,
C          SEE SUBROUTINES BCIC AND OUTPUT.
C
C
C          PROBLEM PARAMETERS ARE READ USING NAMELIST IN THE MAIN
C          ROUTINE.  FOR OTHER INPUT SEE SUBROUTINE BCIC.
C
C
C          THERE ARE A FEW UNCONVENTIONAL (AND FRUSTRATING IF FORGOTTEN)
C          THINGS IN THE PROGRAM.  SEE SUBROUTINES FLCFLD, IMPETA, BCIC,
C          AND OUTPUT, THE COMMENTS ARE INDICATED WITH ASTERISKS ****.
      REAL   ME,MINF
      LEVEL 2,DEPVAR,ABCFD,COEFF,WORK1
      LEVEL 2,U,UJP1,UJM1,V,VJP1,VJM1,W,WJP1,WJM1,H,HJP1,HJM1,
     &        P,PJP1,PJM1,ZI,ZIJP1,ZIJM1,A,B,C,F,DELU,DELV,DELW,DELH,
     &        DELP,DELZI
      LEVEL 2,UNEW,VNEW,WNEW,PNEW,HNEW,ZINEW,HBNEW,VBNEW,ETNEW,FINEW
C          THE ARRAY UVWPHZ IS NEEDED ONLY BECAUSE THE CDC7600 JUMBLES
C          LARGE CORE ARRAYS WHEN THEY ARE INPUT OR OUTPUT WITHOUT
C          FORMAT CONTROL.  THE ARRAY IS USED IN SUBROUTINES BCIC AND
C          OUTPUT.  HERE IT SHOULD BE DIMENSIONED UVWPHZ(MAXK,MAXL,6).
