LAMINAR PIPE FLOW WITH INJECTION AND SUCTION THROUGH A POROUS WALL+

By

S. W. Yuan* and A. Finkelstein**

Polytechnic Institute of Brooklyn

SUMMARY

The effect of injection and suction at the wall on the two-dimensional steady-state laminar flow of a fluid in a porous-wall pipe has been investigated in detail by the solution of the Navier-Stokes equations in cylindrical coordinates. An exact solution of the dynamic equations, reduced to a third-order nonlinear differential equation with appropriate boundary conditions, is obtained. A perturbation method was used to solve the latter equation for both small and large flows through the porous wall.

The velocity components are expressed as functions of the ratio of velocity through the porous wall to the maximum axial velocity at the pipe entrance, the coordinates of the pipe and the physical properties of the fluid.

The results show that the effect of injection at the porous wall of the pipe is to increase the friction coefficient at the wall. For an injection ratio $\frac{Q}{W} = 0.01$ (500 $\leq R_e \leq 2500$) the friction coefficient at the wall is increased by 70-85% over the zero injection case (Poiseuille case).

+ This research was conducted under the auspices of Project SQUID, jointly sponsored by the Office of Naval Research, Department of the Navy, Office of Scientific Research, Department of the Air Force, and Office of Ordnance Research, Department of the Army.

** Research Associate of Aeronautical Engineering.
INTRODUCTION

Studies of the problem of cooling rocket and jet motors by the diffusion of fluids through porous metal combustion chamber liners have been made by means of the investigation of the boundary layer behavior along a porous plate with fluid injection [1]. Laminar flow in a two-dimensional channel with porous walls has also been investigated for extremely small suction velocity at the wall [2]. Since the problem of the flow through a porous-wall pipe with injection has not been thoroughly investigated, the purpose of this work was to obtain the basic phenomena of this type of flow which would provide a guidance for the investigation of turbulent pipe flow with injection or suction.

Another important application of the results of this study is to the boundary layer control for decreasing drag and increasing lift of airplane wings. In this connection the boundary-layer flow is sucked through the surface of the wing to a duct. The ensuing flow in the duct simulates the problem of flow through a pipe with fluid injection at the walls.

In the present investigation an exact solution of the Navier-Stokes equations in cylindrical coordinates with injection or suction as a boundary condition at the wall was obtained. On the other hand the problems of flow on a porous flat plate or curved wall were previously made by the approximate solution of the Prandtl boundary layer equations.

The assumptions made in the present study were: (1) the fluid is incompressible, i.e. the mass density and the viscosity of the fluid were assumed to be constant; (2) the main flow was assumed to be laminar, and the fluid flowing in the axial direction and the fluid flowing through the

*Numbers in brackets refer to Bibliography.*
porous wall were assumed homogeneous; (3) the maximum axial velocity at the entrance of the porous-wall pipe is equal to the maximum axial velocity in the Poiseuille's flow; and (4) the fluid flowing through the porous wall is uniform throughout.

**Fundamental Equations**

The three-dimensional steady flow of a viscous incompressible fluid is governed by the following set of basic laws of fluid mechanics. From Newton's Second law, the Navier-Stokes equations were derived as follows:

\[
(\bar{q} \cdot \nabla) \bar{q} = -\frac{1}{\rho} \nabla p + \nabla \cdot \bar{q}^2 \bar{q}
\]  

(1)

From the principle of conservation of matter,

\[
\nabla \cdot \bar{q} = 0
\]  

(2)

If a curvilinear coordinate system is introduced with the origin at the center of the cross-section where \(x\) is taken in the direction of the flow, \(r\) in the radial direction and \(\theta\) the azimuthal angle, and the ordinary vector curvilinear coordinate transformations are used, the Navier-Stokes and continuity equations become

\[
u \frac{\partial u}{\partial x} + \nu \frac{\partial u}{\partial y} = -\frac{1}{\rho} \frac{\partial p}{\partial x} + \nu \left[ \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial u}{\partial r} \right) + \frac{1}{r^2} \frac{\partial^2 u}{\partial \theta^2} \right]
\]  

(3)

\[
u \frac{\partial v}{\partial x} + \nu \frac{\partial v}{\partial y} = -\frac{1}{\rho} \frac{\partial p}{\partial y} + \nu \left[ \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial v}{\partial r} \right) + \frac{1}{r^2} \frac{\partial^2 v}{\partial \theta^2} \right] + \frac{\partial v}{\partial r} - \frac{v}{r}
\]  

(4)
where \( u \) and \( v \) represent the \( x \) and \( r \) components of the velocity at any point (see Fig. 1) and \( \frac{\partial}{\partial \theta} = 0 \) because of axially symmetric flow.

The above equations will be used to investigate the fluid flow in a circular pipe with a porous wall through which uniform fluid injection or suction is applied. The boundary conditions are

\[
\begin{align*}
\text{at } r = 0 : & \quad v = \frac{\partial u}{\partial r} = 0 \\
\text{at } r = R : & \quad u = 0 \quad , \quad v = -V = \text{const}.
\end{align*}
\]

For a two-dimensional incompressible flow, a stream function exists such that

\[
\gamma u = \frac{\partial \psi}{\partial r} \quad , \quad -r v = \frac{\partial \psi}{\partial x}
\]

and the continuity equation (5) is satisfied.

For a constant fluid injection or suction at the porous wall and the given boundary conditions, the following stream function is introduced:

\[
\psi = (A + B \frac{r}{R}) f(\eta)
\]

where \( \eta = (\frac{r}{R})^2 \). The constant \( A \) is determined from the condition at \( \eta = 0 \) and \( x = 0 \) where the maximum velocity \( U_0 \) for Poiseuille's flow exists. The constant \( B \) is determined from the law of conservation of matter. The stream function can then be expressed as:
From Eqs. (5) and (7) the velocity components in the direction of
flow and the radial direction are given by

\[ u = U_o \left( \frac{1}{f'(\eta)} + 4 \frac{A}{Re} \frac{x}{R} \right) f(\eta) \]

and

\[ v = -2 v_o \frac{f(\eta)}{f'(\eta)} \]

where \( \lambda = \frac{v_o R}{D} \) and \( Re = \frac{U_o R}{v_o} \). The function \( f(\eta) \) appearing in
the above equations is the only unknown yet to be determined in terms of
the distance parameter \( \eta \). Eq. (11) indicates that the radial velocity
becomes a function of \( \eta \) only. This is because of the assumption of
constant velocity \( v_o \) at the wall.

By introducing the expressions of \( u \) and \( v \) from Eqs. (10) and (11) into
the Eqs. (3) and (4) there result

\[ -\frac{1}{f} \frac{d}{dX} \frac{d}{dX} = \frac{4 U_o}{R^2} \left[ \frac{1}{f'(\eta)} + 4 \frac{A}{Re} \frac{x}{R} \right] \left[ RV_o (f'' - f') - \nu (f'' + f'') \right] \]

and

\[ \frac{1}{f} \frac{d}{d\eta} \frac{d}{d\eta} = \frac{2 v_o}{R} \left[ RV_o \left( f'' - \frac{2ff'}{\eta^2} \right) - 2 \nu f'' \right] = F(\eta) \]

Since the right-hand side of Eq. (13) is a function of \( \eta \) only, differentiation
of both sides of it with respect to \( x \) yields

\[ \frac{d^2 f}{dX d\eta} = 0 \]
Hence differentiating Eq. (12) with respect to $\eta$ gives

\[
\frac{d}{d\eta} \left[ RV_0 \left( f'^2 - ff'' \right) - \nu \left( \eta f'' + f' \right) \right] = 0
\]

which is to be satisfied for all $x$.

Integrating Eq. (15), one obtains

\[
\eta f''' + f' - \lambda (f'^2 - ff'') = C
\]

for $\lambda \leq 1$, and

\[
f'^2 - ff'' = \frac{1}{\lambda} (\eta f'' + f') = k
\]

for $\lambda > 1$; where $C$ and $k$ are the constants of integration to be determined. The boundary conditions are obtained with the aid of Eqs. (6), (10) and (11). Thus:

\[
f(0) = f'(0) = 0 \quad \lim_{\eta \to 0} \sqrt{\eta} f''(\eta) = 0
\]

\[
f(1) = \frac{1}{2}
\]

Eq. (16) is an ordinary non-linear differential equation of the third order which resulted from the Navier-Stokes equations and the continuity equation by the similarity transformation. With the aid of the four given boundary conditions an exact solution can be obtained and the constant of integration $C$ determined.
It can be seen that the limiting form of Eq. (16), by letting \( \varepsilon \) approach to zero, is the equation describing a flow through a circular pipe with permeable walls. The solution of this equation which satisfies all the four boundary conditions given in Eq. (18) is the well-known Poiseuille's law for pipe flow. If small values of \( \lambda \) are treated as a perturbation parameter a solution of Eq. (16) can be obtained which will be discussed in the next section.

On the other hand, if large values of \( \lambda \) are treated as a perturbation parameter the third order differential equation (17) is reduced to a second order one. The solution of Eq. (17) can also be obtained in the same manner since all four boundary conditions given in Eq. (18) can be satisfied.

**SOLUTION FOR SMALL \( \lambda \)**

The solution of Eq. (16) can be expressed for small value of \( \lambda \), by a power series developed near \( \lambda = 0 \) as follows:

\[
f = f_0 + \lambda f_1 + \lambda^2 f_2 + \cdots + \lambda^n f_n
\]

and

\[
c = c_0 + \lambda c_1 + \lambda^2 c_2 + \cdots + \lambda^n c_n
\]

where the \( f_n \)'s and \( c_n \)'s are taken to be independent of \( \lambda \).

By substituting Eqs. (19) and (20) into Eq. (16) and equating coefficients of like powers of \( \lambda \), one obtains the following set of equations:

\[
\eta f_0''' + f_0'' = c_0
\]

\[
\eta f_1''' + f_1'' + f_0 f_0'' = c_1
\]
The boundary conditions to be satisfied by the \( f_n \)'s are from Eq. (18):

\[
\begin{align*}
    f_n(0) &= f_n(1) = 0 ; & \lim_{\eta \to 0} \sqrt{\eta} f_n''(\eta) &= 0 \quad \text{for all } n \\
    f_0'' &= \frac{1}{2} \\
    f_n'(1) &= 0 , \quad n \geq 1
\end{align*}
\]

The second-order perturbation solution of Eq. (16) obtained by solving Eqs. (21) to (23) is given as follows:

\[
\eta f_2'' + f_2'' - 2 f_0 f_0' + f_0'' f_0 + f_0 f_0'' = c_2
\]

\[ \tag{23} \]

\[
\begin{align*}
    f(t) &= \left( \eta - \frac{1}{2} \eta^2 \right) + \frac{\lambda}{2} \left( \frac{7}{18} \eta^2 - \frac{7}{8} \eta^4 \right) \\
    &\quad + \lambda^2 \left( \frac{3}{5400} \eta^3 - \frac{1}{144} \eta^5 + \frac{1}{432} \eta^7 - \frac{1}{144} \eta^9 \right) + \frac{1}{720} \eta^7 - \frac{1}{10800} \eta^9
\end{align*}
\]

\[ \tag{25} \]

\[
\begin{align*}
    C &= -1 - \frac{3}{4} \lambda + \frac{11}{270} \lambda^2
\end{align*}
\]

\[ \tag{26} \]

It is seen from the above equations that the second-order perturbation solution is sufficiently accurate even for \( \lambda = 1 \). The velocity components in the axial and radial directions are obtained by substituting Eq. (25) into Eqs. (10) and (11), respectively as follows:
\[
\frac{u}{u_0} = \left[ 1 - \frac{\lambda}{18} + \frac{83}{5400} \lambda^2 \right] \left[ 1 - \frac{\lambda}{36} (-2 + 9\eta - 9\eta^2 + 2\eta^3) + \frac{\lambda^2}{10800} (166 - 760\eta + 825\eta^2 - 300\eta^3 + 75\eta^4 - 6\eta^5) \right]
\]  
(27)

\[
\frac{v}{u_0} = -\frac{2\lambda}{R_e \sqrt{\eta}} \left[ \gamma - \frac{1}{2} \gamma^2 + \frac{\lambda}{72} (-4\eta + 9\gamma^2 - 6\gamma^3 + \gamma^4) + \frac{\lambda^2}{10800} (166\gamma - 380\gamma^2 + 275\gamma^3 - 75\gamma^4 + 15\gamma^5 - \gamma^6) \right]
\]  
(28)

The pressure distribution in the axial and radial directions are obtained upon the substitution of Eq. (25) into Eqs. (12) and (13), and integrating. Then one obtains

\[
\frac{\phi(o, o) - \phi(x, r)}{f u_o^2} = \frac{8}{R_e} \left[ 1 + \frac{3}{4} \lambda - \frac{\eta}{27} \lambda^2 \right] \left[ \frac{1}{f'(o)} + 2 \frac{\lambda}{R_e} \frac{x}{R} \right] \left( \frac{x}{R} \right)
\]

\[
+ 4 \left( \frac{\lambda}{R_e} \right)^2 f \left( \frac{f'}{f} \right)^2 - \frac{8\lambda}{R_e^2} \left[ f'(o) - f'(\gamma) \right]
\]
(29)

The pressure drop in the flow direction can be readily obtained from Eq. (29), i.e.

\[
\frac{\phi(o, r) - \phi(x, r)}{f u_o^2} = \frac{8}{R_e} \left[ 1 + \frac{3}{4} \lambda - \frac{\eta}{27} \lambda^2 \right] \left[ \frac{1}{f'(o)} + 2 \frac{\lambda}{R_e} \frac{x}{R} \right] \left( \frac{x}{R} \right)
\]
(30)
The coefficient of skin friction at the wall can also be obtained from Eq. (27), and can be written

\[ C_f = \frac{\tau_0}{\frac{f u_0^2}{2}} = \frac{4}{Re} \left[ \frac{1}{1 - \frac{\lambda}{18} + \frac{83 \lambda^2}{5400}} + 4 \frac{\lambda}{Re} \frac{x}{R} \right] \left[ 1 + \frac{\lambda}{12} - \frac{13 \lambda^2}{5400} \right] \]

(31)

SOLUTION FOR LARGE \( \lambda \)

The solution of Eq. (17) can be expressed for large values of \( \lambda \), by a power series developed near \( \frac{1}{\lambda} = 0 \) as follows:

\[ f = f_0 + \frac{1}{\lambda} f_1 + \frac{1}{\lambda^2} f_2 + \cdots + \frac{1}{\lambda^n} f_n \]

(32)

and

\[ k = k_0 + \frac{1}{\lambda} k_1 + \frac{1}{\lambda^2} k_2 + \cdots + \frac{1}{\lambda^n} k_n \]

(33)

where the \( f_n \)'s and \( k_n \)'s are taken to be independent of \( \lambda \). By substituting Eqs. (32) and (33) into Eq. (17) and setting all coefficients of like powers of \( \frac{1}{\lambda} \) equal to zero, one obtains the following set of equations:

\[ f_0 f_{0}'' - f_{0}'^2 = k_0 \]

(34)

\[ f_0 f_{1}'' - 2 f_{0}' f_{1}' + f_{0}'' f_{1} + (\gamma f_{0}'''' + f_{0}'') = k_1 \]

(35)

\[ f_0 f_{2}'' - 2 f_{0}' f_{2}' + f_{0}'' f_{2} + f_{1}'' f_{1} - f_{1}'^2 + (\gamma f_{1}'''' + f_{1}'') = k_2 \]

(36)
The boundary conditions to be satisfied by the $f_n$'s are from Eq. (18):

\[
\begin{align*}
  f_n(0) &= f_n'(1) = 0, \quad \lim_{\eta \to 0} \eta f_n''(\eta) = 0 \quad \text{for all } n \\
  f_o(1) &= \frac{1}{2} \\
  f_n(1) &= 0, \quad n \geq 1
\end{align*}
\]

(37)

The first-order perturbation of Eq. (17), obtained by solving the non-linear second-order Eq. (34) and the linear second order Eq. (35), is given as follows:

\[
f(\eta) = \frac{1}{2} \sin \frac{\pi}{2} \eta + \frac{1}{\lambda} \left\{ \left[ A_1 - \frac{\pi}{16} \int_0^1 \frac{5}{\sin \frac{\pi}{2} \xi} \, d\xi \right] \cos \frac{\pi}{2} \eta \\
+ \left[ A_2 - \frac{\pi^3}{16} \int_0^1 \frac{2}{\sin \frac{\pi}{2} \xi} \, d\xi \right] \left[ \frac{2}{\pi} \sin \frac{\pi}{2} \eta - \eta \cos \frac{\pi}{2} \eta \right] \\
- \left[ \frac{3}{2} + \frac{4k}{\pi^2} \sin \frac{\pi}{2} \eta \right] \right\}
\]

(38)

\[
K = -0.61685 - \frac{1.3253}{\lambda}
\]

(39)

where

\[
A_1 = \frac{3}{2} - \frac{\pi^3}{16} \int_0^1 \frac{5}{\sin \frac{\pi}{2} \xi} \, d\xi = 0.72708
\]

\[
A_2 = \frac{\pi}{4} + \frac{3}{2} - \frac{\pi^3}{16} \int_0^1 \frac{5}{\sin \frac{\pi}{2} \xi} \, d\xi = 1.5125
\]

and $k_1 = -1.3253$. 

The velocity components in the axial and radial directions are obtained by substituting Eq. (38) into Eqs. (10) and (11), respectively as follows:

\[
\frac{U}{U_o} = \left[ \frac{1}{0.7854 + 0.8427} \right] + 4 \frac{A}{Re} \frac{x}{R} \left[ \frac{\pi}{4} \cos \frac{\pi}{2} \gamma + \frac{1}{A} f' + \ldots \right]
\]

(40)

\[
\frac{V}{V_o} = - \frac{2A}{Re \sqrt{\gamma}} \left[ \frac{1}{2} \sin \frac{\pi}{2} \gamma + \frac{1}{A} f + \ldots \right]
\]

(41)

The pressure distribution in the axial and radial directions are obtained upon the substitution of Eq. (38) into Eqs. (12) and (13), and integrating

\[
\frac{\phi(0,o) - \phi(x,r)}{\int u_o^2} = \frac{8A}{Re} \left[ 0.61665 + \frac{1}{A} (1.3253) \right] \left[ \frac{1}{f'(0)} + \frac{2A}{Re \sqrt{\gamma}} \left( \frac{x}{R} \right) \right]
\]

+ 4 \left( \frac{A}{Re} \right)^2 \frac{f^2}{\gamma} + \frac{8A}{Re} \left[ f' - f'(0) \right]

(42)

The pressure drop in the flow direction can be readily obtained from Eq. (42), i.e.

\[
\frac{\phi(0,r) - \phi(x,r)}{\int u_o^2} = \frac{8}{Re} \left[ 0.61665 + \frac{1}{A} (1.3253) \right] \left[ \frac{1}{f'(0)} + \frac{2A}{Re \sqrt{\gamma}} \left( \frac{x}{R} \right) \right]
\]

(43)
The coefficient of skin friction at the wall can also be obtained from Eq. (40), which is

$$C_f = \frac{4}{Re} \left[ \frac{1}{0.7854 + \frac{0.8437}{\lambda}} + 4 \frac{\lambda}{Re} \frac{x}{R} \left[ \frac{\pi^2}{8} + \frac{1}{\lambda \left(0.1854\right)} + \ldots \right] \right]$$

(44)

**DISCUSSION**

The velocity distributions in the main flow direction at an arbitrary cross-section of the pipe as calculated from Eq. (27) for $\lambda = -1$ and from Eq. (40) for $\lambda = 10$ are shown in Fig. 2. It was noted that when $\lambda = 0$ the profile becomes Poiseuille's paraboloid, and for $\lambda > 0$ (fluid being injected through the wall) the axial velocity increases and the velocity gradient at the wall increases. For $\lambda < 0$ (fluid being withdrawn through the wall) both the axial velocity and the velocity gradient at the wall decrease as compared with Poiseuille's case. The above phenomenon follows the law of conservation of matter. In the present case the radial velocity, which vanishes in Poiseuille's case, has a finite magnitude except at the center of the pipe where it vanishes.

In Fig. 3 the maximum velocity distributions along the axis of the pipe was shown. The increase of maximum velocity with the increase of fluid injection at the wall and decrease with suction were illustrated in Fig. 4. It was interesting to learn that for an injection ratio $\frac{V_0}{u_0} = 0.01$ ($Re = 1000$) the maximum velocity increases about 35% over the Poiseuille's flow case.
The pressure drop in the main flow direction is shown in Fig. 5. It was found that this pressure drop became appreciably larger, even for very small fluid injection at the wall, than that in the Poiseuille's flow case, and it became appreciably less for small suction case. The ratio between the pressure drop in the radial and the axial directions is approximately equal to the injection (or suction) ratio $\frac{\nu}{u_o}$ and hence the pressure drop in the radial direction can be neglected in most practical applications.

One of the essential parameters in the present investigation is the skin friction coefficient at the wall. In Poiseuille's flow the skin friction coefficient at the wall, $C_f$, has a constant value of $\frac{4}{Re}$. The wall frictional coefficient as calculated from Eqs. (31) and (44) indicates that the effect of injection in a pipe flow is to increase the wall frictional coefficient and the suction to decrease the wall frictional coefficient. In a boundary-layer flow on a porous flat plate the effect of fluid injection at the wall is to increase the thickness of the boundary layer and decrease the velocity gradient at the wall, hence the wall friction decreases in this case. On the other hand in a pipe flow the effect of fluid injection at the wall is to accelerate the main stream velocity hence the velocity gradient at the wall which determines the wall friction increases. For a fluid injection ratio $\frac{\nu}{u_o} = 0.01$ the wall frictional coefficient increases by 85% over the Poiseuille's flow case. The above phenomena were shown in Figs. 6, 7 and 8. The comparison of the variation of local wall frictional coefficient with fluid injection between the case of flow in a porous-wall pipe and on a flat plate was shown in Fig. 9.
