# Title

**Targeting Alpha5 Beta1 Integrin to Prevent Metastatic Breast Cancer Cell Invasion: PhScN Target Site Definition and Plasma Stability**

---

## Abstract

We proposed to test PHSCN and PhScN derivatives with modifications of the N- or C-termini, and/or cysteine side chain to determine the initial spatial constraints of the binding pocket of the ligand to its target site. This will aid in the selection of crosslinking agents, modifications, tag additions and strategies for determination of the target site(s) performed in Aim 2 and lay the foundation for determining the structure-activity relationships (SARS) of these inhibitors with the target.

INTRODUCTION: It has been suggested that PHSCN inhibits metastatic invasion by forming a covalent, disulfide bond with a cysteine residue on the beta1 (β1) subunit of alpha5 beta1 (α5β1) integrin. However, these studies were performed with purified α5β1 integrin, which also produces evidence of covalent bond formation with the α5 subunit (tandem mass spectroscopy data not shown). Hence, the specificity of the reported interaction between PHSCN and the β1 subunit is suspect. Moreover, the cysteine–rich β1 subunit can heterodimerize with 12 distinct alpha integrin subunits, forming integrins that function in many pathways. In contrast, the α5 subunit interacts uniquely with the β1 subunit to induce invasion and support adhesion; thus it is a much more desirable target. Our research tested definitively the hypothesis that both PHSCN and PhScN peptides inhibit α5β1 integrin fibronectin receptor–mediated invasion through noncovalent interaction with α5β1 receptors of SUM149PT and MDA-MB-231 metastatic human breast cancer cells, and laid the foundation for detailed structure–activity relationship (SAR) studies for both peptides as inhibitors of α5β1–mediated metastatic breast cancer invasion.

Objective/Hypothesis: The data, summarized below in Figures 1–6 and in Tables 1–4, and presented in our submitted manuscript, Therapeutic Inhibition of Breast Cancer Bone Metastasis Progression and Lung Colonization: Breaking the Vicious Cycle by Targeting α5β1 Integrin, show that the invasion–inhibitory interaction of PHSCN with α5β1 integrin involves a noncovalent interaction with the target site, which is promoted by including D–isomers of histidine and cysteine in the PhScN peptide. Thus, covalent, disulfide bond formation with α5β1 integrin is actually a side reaction that decreases potency. Because mammalian proteins do not contain D–amino acids, endoproteinas evolved to cleave between L–amino acids only. Since PhScN does not contain 2 linked L–amino acids, it cannot be degraded by endoproteases, usually present at high levels in tumors and increasing with malignancy. Thus, in addition to promoting noncovalent interaction with its α5β1 integrin target, the inclusion of D–amino acids at alternate positions likely results in increased PhScN potency as a result of preventing endoproteolytic degradation.

Finally, the in vivo lung extravasation and colonization data, as well as the bone colony progression data presented in Figures 3, 4, and 5, show that systemic PhScN therapy is a highly effective, well–tolerated systemic mono–therapy for reducing lung colonization and metastasis progression, as well as intratibial progression by metastatic breast cancer. The figures and tables presented in this annual report are listed below.

Figure 1. Hill–Slope plots of increased invasion–inhibitory potency of Ac-PhScN-NH₂, Ac-PhScNGGK-MAP, and the cysteine–modified, methylated (Me) or acetylated (O-Ac) peptides for MDA-MB-231 cells.

**BODY:**

**Increased invasion inhibitory potency of Ac-PhScN-NH₂ and the Ac-PhScNGGK-MAP dendrimer.**

The Hill–Slope plots for the effects of varying concentrations of Ac-PhScN-NH₂, Ac-PHSC(S–OAc)N-NH₂ or Ac-PHSC(S–Me)N-NH₂ on MDA-MB-231 breast cancer cell invasion *in vitro* are shown in Figure 1A. Similar Hill–Slope plots were obtained for SUM149PT, as summarized in Table 1. Moreover, to demonstrate that PhScN targets α5β1–mediated invasion specifically, we also utilized a peptide consisting of the α5β1 integrin–specific ligand [16] from the ninth module of the fibronectin cell–binding domain, Ac-PHSRN-NH₂ (PHSRN) to induce invasion under serum–free conditions, as shown in Figure 1B. Table 1 summarizes the half maximal invasion inhibitory concentration (IC50) and the dose reduction index (DRI) values for PHSCN and its S–methylated [C(Me)N] or S–acetylated [C(O-Ac)N] cysteine derivatives for both MDA-MB-231 and SUM149PT cell lines. IC50 and DRI values based on pg/ml or molar (M) concentrations are also presented for Ac-PhScN-NH₂ (PhScN) and the Ac-PhScNGGK-MAP polylysine dendrimer (cN–MAP) for invasion induced by either serum or PHSRN, under serum–free conditions. As shown here, PhScN was a highly potent inhibitor of serum–free, PHSRN–induced invasion by both MDA-MB-231 and SUM149PT cells. These results demonstrate that PhScN targets α5β1–mediated invasion specifically in both cell lines.

During the development of PHSCN for clinical trials, it was suggested that PHSCN inhibits invasion via disulfide bonding with α5β1 integrin. However, the increased potencies of the S-acetylated or S–methylated PHSCN derivatives, Ac-PHSC(S–OAc)N-NH2 or Ac-PHSC(S-Me)N-NH2, observed for both MDAMB231 and SUM149PT cells, and also seen in prostate cancer cell lines, suggests that the productive mechanism is actually noncovalent; thus, covalent bonding is an unproductive side reaction. The similarity of the invasion–inhibitory potency of the PhScN peptide to that of S–acetylated or S–methylated PHSCN further suggests that the substitutions of L–His with its stereoisomer D–His, and L–Cys with its stereoisomer D–Cys accomplish the same goal as covalent modification of the cysteine side chain, i.e. the prevention of disulfide bond formation. Hence the mechanism of inhibition for both PhScN and PHSCN is noncovalent.

The PhScNGGK-MAP (7500) polylysine dendrimer consisting of 8 subunits of PhScN was also tested and demonstrated an astonishing 10^7–fold increased invasion–inhibitory potency over monomeric PhScN (596 Da). This increase was significantly greater than the 1000–fold increase seen when comparing PHSCNGGK-MAP and PHSCN peptide, as shown above in Table 1. This greatly increased potency demonstrates the potential for creating a multivalent peptide mimetic.

Comparison of dissociation constants (K_d) and competition binding assays for cell surface binding using biotinylated PhScN or PHSCN peptides

The composition of the PHSCN and PhScN peptides is chemically the same; however the D–stereoisomer amino acid substitutions produce differences in the orientation of the side chains on the peptide backbone. These differences could influence the binding of the compound to its target and also help explain the 100,000–fold increase in the PhScN invasion–inhibitory potency.

A binding assay using biotin–labeled PHSCN was developed during preparation for clinical trials. This assay allows for determination of the dissociation constant (K_d) of a biotin–labeled peptide to suspended cells. Biotinylated derivatives of PHSCN and PhScN were obtained and first evaluated for inhibitory potency in the SU-ECM in vitro invasion assay. The IC50’s of the new compounds, Ac-PhScNGGK-Bio and Ac-PHSCNGGK-Bio were found to be very similar to those of the parental Ac-PhScN-NH2 and Ac-PHSCN-NH2 peptides for both suspended MDA-MB-231 cells (Figure 2A, Table 2) and SUM149PT cells (Table 2). Hence, the presence of the additional –GGK residues and the biotin moiety did not adversely affect the invasion–inhibitory potencies in MDA-MB-231 and SUM149PT cells.

As shown in Figure 2B and summarized in Table 2, the dissociation constant (K_d) values for the Ac-PHSCNGGK-Bio binding to suspended SUM149PT and MDA-MB-231 cells were estimated to be 0.028 and 0.032 μM, respectively. The K_d values for Ac-PhScNGGK–Bio were estimated to be 0.029 and 0.053 μM for suspended SUM 149PT and MDA-MB-231 cells, respectively. The values are very similar for both PHSCN
and PhScN, thereby supporting the hypothesis that the improved invasion–inhibitory potency of PhScN (Table 1) is due to the elimination of the nonproductive covalent side reaction, rather than to tighter binding as a result of orienting the D-cysteine side chain to the opposite side of the peptide ligand. This is also consistent with our observations for metastatic prostate cancer cell lines\textsuperscript{17}, and demonstrates that the noncovalent interaction is the key to invasion–inhibitory efficacy.

Competition assays were also performed to confirm that PHSCN and PhScN interact with the same binding site in breast cancer cells, as was found for DU 145 and PC-3 prostate cancer cells\textsuperscript{17}. Results of competition assays, in which suspended MDA-MB-231 cells were incubated with a constant concentration (0.1 \( \mu \)M) of biotinylated Ac-PHSCNGGK–Bio and varying concentrations of unlabeled Ac-PhScN-NH\(_2\), are presented in Fig. 2C. These results show that the dissociation of Ac-PHSCNGGK–Bio with increasing concentrations of unlabeled Ac-PhScN-NH\(_2\) occurs over approximately 2 orders of magnitude, and demonstrates that PhScN and PHSCN are competing for the same binding site on MDA-MB-231 cells\textsuperscript{18}. Similar results were obtained for SUM149PT, \textit{data not shown}.

Increased potencies of the PhScN peptide and PhScNGGK–MAP dendrimer as inhibitors of lung extravasation

Extravasation of tumor cells to the lung and successful colonization are late stages in breast cancer progression that are ultimately fatal. Hence, prevention of extravasation which leads to colony formation would increase life expectancy. Cell surface α5β1 integrin has been shown to play a key role in extravasation. Furthermore, PHSCN has been shown to inhibit α5β1–mediated invasion specifically, and to reduce or prevent lung metastasis in preclinical models. Moreover, systemic PHSCN(ATN-161) was found to be well–tolerated, and to delay disease progression for 4 to 14 months in Phase I clinical trial. Since Ac-PhScN-NH$_2$ exhibited a 100,000–fold greater inhibitory potency in vitro, on naturally occurring basement membranes, we compared the efficacies of PhScN and PhScNGGK–MAP with the PHSCN peptide as inhibitors of lung extravasation by breast cancer cells in athymic mice.

To assess their efficacies, treatment groups—each consisting of 10 mice—received a single systemic pretreatment with the appropriate peptide or dendrimer concentrations by tail vein injection. Then, DiI–labeled MDA-MB-231 or SUM149PT cells, briefly prebound to the appropriate concentrations of peptide, were injected into the tail veins of the pretreated mice. The lungs were extracted 24 hours later. A graph of the mean number of extravasated cells per section, and the resulting dose response curves for inhibition of SUM149PT and MDA-MB-231 lung extravasation are presented in Figures 3A and 3B, respectively; and the IC$_{50}$ and DRI values are summarized in Table 3. Each point shows the mean and SEM obtained from confocal microscopy analysis of 20 sections of 10 micron thickness, each separated by 200 microns, from each of a total of 10 mice for each treatment group. Figure 3C shows typical examples of sectioned lung tissue for MDA-MB-231 extravasation analyzed by confocal microscopy after pretreatment with 100 ng/ml Ac-PhScN-NH$_2$ or 100 ng/ml Ac-PHSCN-NH$_2$ compared to untreated control. Figure 3D shows typical examples of sectioned lung tissue for SUM149PT extravasation analyzed by confocal microscopy after pretreatment with 100 ng/ml Ac-PhScN-NH$_2$ or 100 ng/ml Ac-PHSCN-NH$_2$, compared to untreated control. Images represent the merged composite of fluorescent DiI–labeled cells shown in orange; fluorescent blue–stained nuclei from DAPI–containing mounting medium; and fluorescent green anti–actin staining of cytoplasm. Lung extravasated MDA-MB-231 and SUM149PT cells had very similar appearance, as shown in Figs. 3C and 3D. The median–affect plots of Fig. 3B show that increasing concentrations of the PhScN or PHSCN peptides, or the PhScNGGK–MAP dendrimer, decrease SUM149PT and MDA-MB-231 extravasation in a log–linear fashion, with similar relative potencies in both cell lines. In contrast, pretreatment with 1 g per ml Ac-hSPNC-NH$_2$ scrambled sequence control, followed by a single systemic treatment at the equivalent dose, had no inhibitory effect on lung extravasation, data not shown. As shown In Table 3, the PhScN peptide appears to be 100– to 1000–fold more potent than the PHSCN peptide at inhibiting lung extravasation by both SUM149PT and MDA-AB-231 cells. Moreover, the
PhScNGGK–MAP dendrimer appears to be 100,000– to 1,000,000–fold more potent than PHSCN at inhibiting lung extravasation by SUM149PT and MDA-MB-231 (Table 3). These in vivo values correlate well with those seen in the in vitro invasion assay (Table 1) using isolated, naturally occurring basement membranes.

Increased potency of the PhScN peptide as an inhibitor of lung colonization

Since extravasated cancer cells may be limited in their ability to establish a metastatic colony\(^{24}\), effects of PhScN or PHSCN pretreatment on subsequent lung colony formation were also evaluated after extravasated cells were allowed to grow \textit{in vivo} without further treatment for 6 weeks. Figure 4A presents a comparison of the efficacies of prebinding various concentrations of PhScN or PHSCN to suspended, Dil–labeled SUM149PT or MDA-MB-231 cells on lung colonization after tail vein injection. The dose response curves are presented as median effect plots in Fig 4B, and the IC\(_{50}\) and DRI values are summarized in Table 4. Each value represents the mean and SEM from a total of 20 sections of 10 micron thickness, each separated by 200 microns, from each of 10 mice per treatment group. Figure 4C shows typical examples of Dil–labeled MDA-MB-231 lung colonies in fluorescent actin– and DAPI–stained lung tissue after no treatment, and after prebinding of the injected cells to 100 ng/ml of either PHSCN or PhScN. Dil–labeled SUM149PT lung colonies had a similar appearance, \textit{data not shown}. Since induction of cell death, for example by apoptosis, could contribute significantly to the potency of systemic PhScN as an inhibitor of lung colonization, we assessed apoptosis induction \textit{in vitro} in adherent SUM149PT cells by examining the effects of a 1–hour treatment with a range of Ac-PhScN-NH\(_2\) concentrations. Figure 4D presents a typical Western blot indicating that PhScN does rapidly induce a dose–dependent upregulation of activated Caspase-3 in adherent SUM149PT cells; but concentrations required are 1,000– to 100,000–fold higher than those required for lung colonization inhibition. Effects of 500 \(\mu\)g Ac-hSPNc-NH\(_2\) per 10\(^6\) SUM149PT cells, are also shown. The lack of activated Caspase–3 upregulation in SUM149PT cells treated with hSPNc demonstrates that although high PhScN concentrations are required for the upregulation of activated Caspase–3, the effect is sequence–specific.

Qualitatively, MDA-MB-231 and SUM149PT respond similarly to both PHSCN and PhScN; however, the corresponding IC\(_{50}\) values are 10– to 100–fold higher for SUM149PT cells (Table 3). This may be due to the nature of the specific cell preparations or perhaps the differences between a metastatic cancer line (MDA-MB-231) and an inflammatory cell line (SUM149PT). Regardless of the IC\(_{50}\) values, the overall DRI values determined for both MDA-MB-231 and SUM149PT cells suggest that PhScN is 1000– to 10,000–fold more potent at preventing lung colonization than PHSCN. Since stress, due to hypoxia for example, has been shown to increase activated \(\alpha5\beta1\) receptor levels\(^{25}\), we checked whether Ac-PhScN-NH\(_2\) treatment could induce apoptosis in breast cancer cells. We found that very elevated concentrations of (100, 200 and 300 \(\mu\)g/ml) of Ac-PhScN-NH\(_2\) could induce caspase-3 upregulation in adherent SUM149PT cells; but that lower levels (10 and 50 \(\mu\)g/ml) had no effect, as shown in Figure 4D.

Figure 4.
Inhibition of bone metastasis progression by systemic PhScN therapy of mice after intratibial injection of metastatic human MDA-MB-231 breast cancer cells

In breast cancer, metastasis to the bone is usually an earlier disease event than lung colonization. The interaction of bone–metastatic breast cancer cells with the surrounding bone marrow and matrix is best described by the “vicious cycle” model. In this model, parathyroid hormone related protein (PTHrP) expressed by breast cancer cells after bone colonization, stimulates progression and enhances osteoclastic bone resorption through its effects on osteoblasts; moreover, it has been shown to enhance osteoclastic bone resorption in MDA-MB-231 bone metastases. Furthermore, PTHrP is a key mediator of osteoclast activation. In response to signals from metastatic breast cancer cells, bone lining osteoblasts express osteoclast–stimulatory factors, like receptor activator of nuclear kappa B ligand (RANKL), which stimulate osteoclast precursors to generate multinucleated osteoclasts. These activated osteoclasts resorb mineralized bone matrix to release sequestered growth factors that promote metastatic growth by stimulating angiogenesis. Activated α5β1 receptors of microvascular endothelial cells interact with the PHSRN sequence of pFn cell–binding domain fragments to induce angiogenic invasion. Furthermore, MDA-MB-231 colonies in the bones of athymic mice have been shown to induce angiogenesis in osteolytic metastases. The identification of α5β1 integrin as the primary integrin fibronectin receptor on human bone marrow stroma suggests that PhScN could be effective in reducing bone metastases.

Microvascular endothelial cells (hmvec) were tested in our in vitro invasion assay as described, and both PHSCN and PhScN were confirmed to block invasion. The IC₅₀ values were similar to those determined for MDA-MB-231 and SUM149PT cells; and PhScN demonstrated a 6.3 x 10⁻¹-fold increase in potency over PHSCN (PhScN IC₅₀, 1.3 x 10⁻¹³ M; PHSCN IC₅₀, 8.4 x 10⁻⁹ M).

To assess the effects of PHSCN and PhScN on established bone metastases, DiI–labeled MDA-MB-231 cells were injected intratibially into athymic mice, and were allowed to grow into intra-osteal colonies for two weeks before thrice-weekly systemic treatments of 5 or 50 mg/kg of PhScN or PHSCN, respectively, were initiated. The MDA-MB-231 cells were not pretreated with either PhScN or PHSCN peptide prior to intratibial injection. Furthermore, mice received no systemic treatments of any kind for 2 weeks after intratibial injection. After 2 weeks of untreated intratibial MDA-MB-231 growth, systemic treatments were initiated. Treatments were continued for 24 days; with each mouse receiving a total of 10 systemic treatments. As shown in Fig. 5A, 50 mg/kg systemic PhScN monotherapy reduced bone colony progression by about 77%, compared to a reduction of 57% for 5 mg/kg PHSCN. Results of median effect analysis, shown in Fig. 5B, indicate a dosage IC₅₀ of 0.4 mg/kg for PhScN and 10 mg/kg for PHSCN. The calculated DRI value indicates that PhScN is 25–fold more potent than PHSCN as a systemic inhibitor of bone metastasis progression. As seen in the examples obtained from confocal microscopy, shown in Fig. 5C, few MDA-MB-231 cells remained in the intratibial bone marrow of mice treated with 50 mg/kg PhScN; whereas significantly more cells were present in the marrow of mice treated with 50 mg/kg PHSCN. As shown in the image from mice receiving 50 mg/kg PHSCN therapy, bone colonies appeared to be either extravascular, or closely associated with the vasculature.
Colocalization of Ac-PhScNGGK-Bio with Dil in extravasated breast cancer cells

Since additional nodal metastases are identified in at least 20% of patients who undergo a completion axillary lymph node dissection (ALND) following a sentinel lymph node biopsy (SLNB) in which micrometastases were identified, the use of SLNB alone for staging the axilla may lead to the underestimation of the extent of nodal disease in 20% of cases\textsuperscript{41}. Hence, a more efficient means of detecting bone–metastatic disease would be very beneficial. The potency of Ac-PhScN-NH\textsubscript{2} as a noncovalent inhibitor of α5β1–mediated invasion \textit{in vitro}, as well as lung extravasation and metastasis, and bone colonization, suggested that the labeled PhScN peptide, Ac-PhScNGGK-Bio, might be an effective detection agent for extravasated, potentially metastatic breast cancer cells in sectioned biopsies. Thus, we assessed the ability of Ac-PhScNGGK-Bio to colocalize with Dil in lung–extravasated SUM149PT inflammatory breast cancer cells after they were introduced by tail vein injection. As shown in Figure 6A, 5.0 to 50.0 μg per ml of biotinylated Ac-PhScNGGK-Bio peptide labeled 89% to 90% of extravasated SUM149PT cells in lung tissue sections of athymic mice, harvested 24 h after intravenous injection. Figure 6B shows representative images of detection of Dil–labeled SUM149PT, with and without colocalization of Ac-PhScNGGK–Bio. These results suggest that labeled PhScN could be an efficient agent for detecting extravasated breast cancer cells, which specifically express activated α5β1 integrin and hence are invasive and potentially metastatic.
Since recurrent or metastatic disease develops in at least 40% of early breast cancer patients\(^42\), with bone metastasis occurring in most\(^27\), there is an urgent need for an effective, well–tolerated, therapy which can prevent both metastatic and angiogenic invasion. As summarized below in **Scheme 1**, the ability to inhibit activated \(\alpha_5\beta_1\) integrin receptors on metastatic breast cancer cells and their associated angiogenic, microvascular endothelial cells, may form the basis of an effective targeted therapy to inhibit the vicious cycle of breast cancer bone metastasis progression.

Overexpression of parathyroid hormone related protein, PTHrP, in MDA-MB-231 breast cancer cells has been shown to induce a 10–25–fold upregulation of \(\alpha_5\) integrin promoter activity resulting in increased \(\alpha_5\beta_1\) integrin levels\(^43\). Furthermore, radiation has also been shown to stimulate invasion by inducing surface
upregulation of activated α5β1 integrin. Because α5β1 integrin mediates metastatic invasion to cause systemic dissemination, as well as microvascular endothelial cell invasion to promote angiogenesis, we have pursued α5β1 as a therapeutic target. Matrix metalloproteinase-1 (MMP1), is induced by the interaction of α5β1 integrin with the PHSRN sequence of the fibronectin cell binding domain, and mediates both angiogenic and metastatic invasion by breast, prostate, and pancreatic cancer cells. MMP-1 has also been shown to activate the protease activated receptor-1 (PAR-1) gene in both breast cancer and endothelial cells, thereby promoting breast cancer invasion, as well as angiogenesis. PTHrP has been shown to stimulate osteoblasts to induce osteoclast progenitor differentiation into active osteoclasts, which mediate bone resorption, thereby releasing epidermal growth factor (EGF)-like growth factors to further stimulate bone metastasis progression. Our research has shown that overexpression of receptor tyrosine-protein kinase erbB-2 or HER2, a member of the EGF receptor family, causes constitutive, serum-induced, pFn-dependent α5β1-mediated invasion by immortalized mammary epithelial cells, due to surface down regulation of the invasion-inhibitory α4β1 fibronectin receptor. The results of these studies thus suggest that inflammatory growth factors released as a result of bone resorption induce upregulation of activated α5β1 receptors to promote metastatic invasion of the bone, as well as angiogenic invasion to support bone colony progression. Hence, as summarized in Scheme 1, the α5β1 integrin fibronectin receptors of both bone–metastatic breast cancer cells and the microvascular endothelial cells of the bone marrow play a key role in the vicious cycle of bone metastasis.

**Figure 1.** Hill–Slope plots of increased invasion inhibitory potency of Ac-PhScN-NH₂ peptide, Ac-PhScNGGK-MAP dendrimer, and the cysteine–modified, methylated (Me) or acetylated (O-Ac) peptides, Ac-PHSC(Me)N-NH₂ and Ac-PHSC(O-Ac)N-NH₂ for MDA MB-231 cells. Panel A, effects on FBS–induced invasion by cysteine–modified Ac-PHSC(Me)N-NH₂ or Ac-PHSC(O-Ac)N-NH₂, and D–His, D–Cys containing Ac-PhScN-NH₂ peptides. Symbols are denoted in the figure. X axis, log peptide concentration in pg per ml; Y axis, mean relative percentages of invaded cells (+/- SD). IC₅₀ and DRI values are summarized in Table 1. Panel B, Increased potencies of PhScN peptide and PhScN dendrimer for both serum–induced, and serum–free, Ac-PHSRN-NH₂ (1 ng/ml)–induced, α5β₁–mediated invasion. Circles denote Ac-PhScN-NH₂, and squares denote Ac-PhScNGGK-MAP dendrimer, closed symbols denote FBS induced and open symbols denote Ac-PHSRN-NH₂ (1 ng/ml) induced. X-axis, log peptide concentration in pg/ml; Y-axis, mean relative percentage of invaded cells (±SD). The solid and dashed line represent published values for Ac-PHSCN-NH₂ and Ac-PHSCNGGK-MAP respectively.

**Figure 2.** Panel A, Hill–Slope plots of invasion inhibition by biotinylated derivatives of PHSCN and PhScN for MDA-MB-231 cells induced by FBS. Specific agents (CN-Bio, Ac-PHSCNGGK-Bio; cN-Bio, Ac-PhScNGGK-Bio) are listed on the right. X axis, log peptide concentration in pg per ml; Y axis, mean relative percentages of invaded cells (+/- SD). IC₅₀ and DRI values are summarized in Table 2. Panel B, Kₐ binding assays for Ac-PHSCNGGK-Bio (CN-Bio) and Ac-PhScNGGK-Bio (cN-Bio) peptides with suspended MDA MB231 cells. Plots were fit using a total binding equation to account for nonspecific binding(Motulsky and Neubig 2010). Panel C, Competition binding was determined by incubating suspended MDA-MB-231 cells with a constant concentration of 0.1 M Ac-PHSCNGGK–Bio (labeled) and varying amounts of unlabeled Ac-PhScN-NH₂. Plot was fit using a competitive inhibition equation.¹⁸

**Figure 3.** Increased extravasation inhibition by Ac-PhScN-NH₂ or Ac-PhScNGGK–MAP prebinding, relative to Ac-PHSCN-NH₂ peptide. Panel A, Y axes, average cells extravasated/section; X Axes, Con, control; 10, 100, 1000 ng/ml PHSCN; 1, 10, 100 ng/ml PhScN; 1, 10, 100 pg/ml PhScN-MAP. Panel B, Median–affect plot for extravasation into lung after prebinding with PHSCN (circles), PhScN (squares) or PhScN-MAP (triangles); open symbols, MDA-MB231 cells; closed symbols, SUM 149 PT cells. X axes, log peptide concentration in ng/ml; Y axes, mean log fraction affected/fraction unaffected (fᵢ/f₀) +/- SEM. IC₅₀ and DRI values are summarized in Table 3. Panel C. Typical examples of sectioned lung tissue for MDA-MB231 extravasation analyzed by confocal microscopy after pretreatment with 100 ng/ml Ac-PhScN-NH₂ or 100 ng/ml Ac-PHSCN-NH₂, compared to untreated control. Panel D. Typical examples of sectioned lung tissue for SUM149PT extravasation analyzed by confocal microscopy after pretreatment with 100 ng/ml Ac-PhScN-NH₂ or 1000 ng/ml Ac-PHSCN-NH₂, compared to untreated control. Images represent the merged composite of Dil–labeled cells shown in orange; blue stained nuclei from DAPI Mounting Medium; green tissue from actin staining.

**Figure 4.** Increased inhibition of lung colonization by Ac-PhScN-NH₂ prebinding, relative to Ac-PHSCN-NH₂. Panel A, Y axes, average colonies/section; X Axes, Con, control; NC, 100 ng/ml HSPNC; 10, 100, 1000 ng/ml PHSCN; 1, 10, 100 ng/ml PhScN Panel B, Median–effect plot for lung colony formation after prebinding to PHSCN (circles) or PhScN (squares). Closed symbols, dotted lines, SUM149PT cells; Open symbols, solid line MDA-MB-231 cells. X axes, log peptide concentration in ng/ml. Y axes, mean log fraction affected/fraction unaffected (fᵢ/f₀) +/- SEM. IC₅₀ and DRI values are summarized in Table 4. Panel C. Typical examples of
sectioned lung tissue for MDA-MB231 colonization analyzed by confocal microscopy after pretreatment with 100 ng/ml Ac-PhScN-NH₂ or 100 ng/ml Ac-PHSCN-NH₂ compared to untreated control. Images represent the merged composite of DiI-labeled cells shown in orange; blue stained nuclei from DAPI Mounting Medium; green tissue from actin staining. Panel D. Example of a Western blot showing dose–dependent upregulation of activated Caspase–3 in adherent SUM149PT cells by a one–hour treatment with a range of Ac-PhScN-NH₂ concentrations (10, 50, 100, 200, or 300 µg/10⁶ cells). Micrograms of Ac-PhScN-NH₂ per million SUM149PT cells are indicated. Effects of an elevated concentration of a scrambled sequence control, 500 µg Ac-hSPNc-NH₂ per 10⁶ SUM149PT cells, are also shown.

Figure 5. Increased potency of PhScN as a systemic therapy to prevent breast cancer bone colony progression in athymic mice. A. Anti–metastatic potencies of systemic PhScN (Ac-PhScN-NH₂) vs. PHSCN (Ac-PHSCN-NH₂) for reducing MDA-MB-231 bone marrow progression in athymic mice. Y axes, average cells per section; X Axes, Con, untreated control; 5 and 50 mg/kg PhScN; 5 and 50 mg/kg PHSCN. B. Median effect plot for effects of PhScN vs PHSCN on bone marrow progression, X axis, log peptide dosage level (mg/kg); Y axis, mean log fraction affected/fraction unaffected (fa/fu) +/- SEM. C. Examples of bone marrow from untreated mice, and from mice treated with a total of 10 thrice–weekly tail vein injections: 50 mg/kg PhScN or PHSCN. Images represent merged composites of DiI-labeled cells (orange); blue–stained nuclei (DAPI Mounting Medium); green cytoplasm (actin staining). Thus, DiI–labeled cells appear orange (Control) or green with orange inclusions (50 mg/kg PHSCN). No DiI–labeled cells appear in the image of bone marrow from 50 mg/kg PhScN–treated mice.

Figure 6. Colocalization of Ac-PhScNGGK-Bio with DiI in lung–extravasated SUM149PT cells. A. Percentage of DiI–labeled cells in lung tissue binding to different concentrations of Ac-PhScNGGK-Bio: 1, 5, or 50 µg per ml. X axis, binding agents: hSPNc, Ac-hSPNc-NH₂ (scrambled sequence control peptide); PhScN, Ac-PhScNGGK-Bio. Y axis, mean percentage of biotinylated, DiI–labeled SUM149PT cells (+/- SEM). B. Examples of fluorescently stained lung tissue: control, no PhScNGGK-Bio; 50 µg PhScNGGK-Bio, 50 µg per ml Ac-PhScNGGK-Bio. DiI–labeled cells shown in orange; blue stained nuclei from DAPI Mounting Medium; green tissue from actin staining.

Specific Aim 3
Develop a mass spectrometry–based quantitative assay for PHSCN analogs, including PhScN, and evaluate their stabilities in human and mouse plasma.

Experimental design for quantitative assay of PHSCN analogs
An experimental approach based on mass spectrometric analysis to evaluate the stabilities of PHSCN analogs in human and mouse plasma has been designed as outlined below in Scheme 1. A known amount of target peptide is mixed with plasma and incubated at 37 °C for up to 24 hours. At specific incubation time points an aliquot is transferred to a small tube and protease reactions were quenched by adding three volumes of 50% acetonitrile with 0.5%TFA. Precipitated plasma proteins were removed by centrifugations, and a known amount of an internal standard was spiked into the supernatant containing the peptides, in order to
increase the accuracy of quantitative measurements of LC-MS by reducing variances associated with sample preparations. MRFA (Met-Arg-Phe-Ala, monoisotopic molecular mass = 523.247.), a stable synthetic peptide with similar molecular mass to the target peptide, Ac-PHSCN-amide (monoisotopic molecular mass = 597.2328), is added into samples prior to LC-MS analysis. Stabilities of target peptides in plasma were evaluated by LC-MS.

**Mass spectrometry**
The LTQ-Orbitrap XL (Thermo Finnegan) connected to a 2D nanoLC (Exigent) and an autosampler in Andrews laboratory provides high mass resolution and accuracy for analytes separated on a capillary column at a flow rate of 200 nL/min, which assures confident identification of target molecules. Extracted peptides from plasma are reconstituted in 0.1% TFA and loaded into a C18 trap by autosampler and washed for 6 min at 5 microL/min with 0.1% TFA in water delivered by the LC loading pumps. Trapped peptides were introduced by switching valve into a capillary column (75 micro-m x 15 cm) custom-packed with C18 resin (3 micron) and separated over 60 min gradient at a flow rate of 200 nL/min. Analytes were introduced into the LTQ-Orbitrap via an electrospray device (Triversa Nanomate, Advion). MS and MSMS data were acquired in data-dependent mode for ions within 400-800 m/z. Figure 7 shows the total ion chromatogram (TIC) of LC-MSMS analysis of PHSCN and the internal standard MRFA.

![Figure 7. TIC from an LC-MSMS of PHSCN and MRFA mixture.](image)

**Quantitative assay of target peptides**
Peptide quantification can be achieved by ion intensities in MS or by MSMS spectral counts in data-dependent acquisition mode. These two approaches are well established label-free quantification methods for peptides and proteins by LC-MSMS, which can be readily applied to a bioanalytical assay of therapeutic peptides. We are currently testing a new assay method, an MRM-like analysis via data-independent acquisition mode in the LTQ-Orbitrap, in which ion packets within a mass range of 5 or 10 Da accumulated for a set time are co-fragmented.
One or multiple fragment ions specific to the target peptide can be monitored in MSMS based on highly accurate precursor ion mass and LC retention time. This MRM-like approach can provide a highly selective and sensitive bioanalytical assay under conditions of high chromatographic interference.

**Study of collision–induced dissociation (CID) fragmentation of Ac-PHSCN-NH₂ in online LC-LTQ-Orbitrap**

Ac-PHSCN-NH₂ introduced into the mass spectrometer via a nanoESI device (Triversa Nanomate) was predominantly observed as singly protonated form at 598.2328 m/z. However, in online LC-MS, the peptide was observed in doubly charged dimeric forms at 597.23 m/z and 589.23 m/z. The peptide dimer ions were characterized by CID that revealed disulfide-bond formation between two peptides that was catalyzed on C18 LC, as shown in a CID spectrum of 597.23 m/z. This is a potential source of interference with the assay that can be easily addressed by incorporating reduction and alkylation of the Cys residues into the protocol prior to LCMSMS although introduction of an additional step in the process could increase the variance slightly. The reason that dimerization occurs during the LC separation but not during other manipulations or assay approaches is not clear.

Figure 8. CID fragmentation of doubly–charged ion at 597.73 m/z (the second isotope to 597.23 m/z). Fragment ions B4, A2, Y2,Y3, and Y4 containing S-S cross-linked peptides confirm disulfide bond formation between two thiols of cysteine.

**KEY RESEARCH ACCOMPLISHMENTS:**

1. Determination of invasion–inhibitory potencies for a total of 12 PHSCN and PhScN derivatives, targeting α5β1 integrin–mediated invasion of naturally serum–free basement membranes by 2 metastatic human breast cancer cell lines, SUM149PT and MDA-MB-231. Demonstration that covalent S–modification by several different moieties increases invasion–inhibitory potency by 100,000– to 1,000,000–fold, and that a 1,000,000–fold increase in potency is also obtained by substitution of D–His and D–Cys. These results
demonstrate that the reason for the greatly increased invasion–inhibitory potency of PhScN is the suppression of covalent disulfide bond formation between the PHSCN sequence and its integrin target, and hence they are a key step in the determination of the PhScN target site on α5β1 integrin receptors of breast cancer cells.

2. Determination of invasion–inhibitory potencies of PHSCN and PhScN peptides, containing BPM–derivatized cysteine or D–cysteine. The greatly increased invasion–inhibitory potencies of the BPM–modified PHSCN and PhScN peptides also confirm the noncovalent nature of invasion inhibition by the PhScN peptide.

Research accomplishments 1 and 2 complete Specific Aim 1 of the SOW.

3. Crosslinking with BPM–derivatized peptides, after integrin α5β1 activation with divalent cations, and analysis by Western blotting. Successful crosslinking with biotin labeled peptides, modified either at the cysteine or on the C–terminus, is anticipated to pave the way for protein enrichment and binding site identification by MS/MS. Our experiments demonstrating specific tagging of the integrin target indicate that significant scale-up will be required to obtain sufficient quantities for identification of the binding domains.

4. Determination of binding constants for PHSCNGGK-Bio and PhScNGGK-Bio on MDA-MB-231 and SUM149PT cells, and demonstration of their similarity provides the basis for acquiring information on any steric hindrances introduced by modification of the ligands not detected in functional invasion assays.

5. Demonstration that PHSCNGGK-Bio and PhScNGGK-Bio compete for the same binding site on SUM149PT and MDA-MB-231 cells. The results of these binding assays, in conjunction with the functional invasion inhibition results shown in Table 1, will allow a more complete profile of the peptide ligand properties and their functional effects on α5β1 integrin–mediated invasion. Moreover, these results provide key support of the hypothesis that the increased potency of the PhScN peptide results from suppression of covalent, disulfide bond formation with the integrin target.

Research accomplishments 3, 4, and 5 provide key support towards accomplishing Specific Aim 3 of the SOW.

6. Demonstration of CID fragmentation of Ac-PHSCN-NH₂ in online LC-LTQ-Orbitrap indicates that development of a mass spectrometry–based quantitative assay for PHSCN analogs, including PhScN, for the purpose of evaluating their stabilities in human and mouse plasma (Specific Aim 3) is feasible although the methods to suppress the formation of disulfide dimers during the separation procedure must be developed.

REPORTABLE OUTCOMES: The following manuscript has been submitted for publication; and after review, a revised version is now under consideration by reviewers: Yao HY, Veine DM, and Livant DL (2015) Therapeutic Inhibition of Breast Cancer Bone Metastasis Progression and Lung Colonization: Breaking the Vicious Cycle by Targeting α5β1 Integrin.

CONCLUSION: The PhScN peptide is a highly potent inhibitor of α5β1 integrin–mediated, serum–induced invasion because it suppresses covalent, disulfide bond formation with its target. Moreover, results of competition assays show that it targets the same region of α5β1 integrin as the PHSCN peptide parent.
