14. ABSTRACT
The investigators have undertaken several quantum engineering and phonon engineering efforts underlying the enhancement of the performance of nanostructure-based sensors and electronicoptoelectronic devices. These include: design of novel photodetectors relying on phonon-assisted transitions as well as photon absorption events; AlGaAs/GaAs triple well photodetector; spontaneous polarization induced electric fields in nanostructures. This research includes modeling and theory of quantum confined structures as well as related experimental studies.

15. SUBJECT TERMS
Heterostructure devices; phonon-assisted transitions; quantum-well devices
INSTRUCTIONS FOR COMPLETING SF 298

1. REPORT DATE. Full publication date, including day, month, if available. Must cite at least the year and be Year 2000 compliant, e.g. 30-06-1998; xx-06-1998; xx-xx-1998.

2. REPORT TYPE. State the type of report, such as final, technical, interim, memorandum, master's thesis, progress, quarterly, research, special, group study, etc.

3. DATES COVERED. Indicate the time during which the work was performed and the report was written, e.g., Jun 1997 - Jun 1998; 1-10 Jun 1996; May - Nov 1998; Nov 1998.

4. TITLE. Enter title and subtitle with volume number and part number, if applicable. On classified documents, enter the title classification in parentheses.

5a. CONTRACT NUMBER. Enter all contract numbers as they appear in the report, e.g. F33615-86-C-5169.

5b. GRANT NUMBER. Enter all grant numbers as they appear in the report, e.g. AFOSR-82-1234.

5c. PROGRAM ELEMENT NUMBER. Enter all program element numbers as they appear in the report, e.g. 61101A.

5d. PROJECT NUMBER. Enter all project numbers as they appear in the report, e.g. 1F665702D1257; ILIR.

5e. TASK NUMBER. Enter all task numbers as they appear in the report, e.g. 05; RF0330201; T4112.

5f. WORK UNIT NUMBER. Enter all work unit numbers as they appear in the report, e.g. 001; AFAPL30480105.

6. AUTHOR(S). Enter name(s) of person(s) responsible for writing the report, performing the research, or credited with the content of the report. The form of entry is the last name, first name, middle initial, and additional qualifiers separated by commas, e.g. Smith, Richard, J, Jr.

7. PERFORMING ORGANIZATION NAME(S) AND ADDRESS(ES). Self-explanatory.

8. PERFORMING ORGANIZATION REPORT NUMBER. Enter all unique alphanumeric report numbers assigned by the performing organization, e.g. BRL-1234; AFWL-TR-85-4017-Vol-21-PT-2.

9. SPONSORING/MONITORING AGENCY NAME(S) AND ADDRESS(ES). Enter the name and address of the organization(s) financially responsible for and monitoring the work.

10. SPONSOR/MONITOR'S ACRONYM(S). Enter, if available, e.g. BRL, ARDEC, NADC.

11. SPONSOR/MONITOR'S REPORT NUMBER(S). Enter report number as assigned by the sponsoring/monitoring agency, if available, e.g. BRL-TR-829; -215.

12. DISTRIBUTION/AVAILABILITY STATEMENT. Use agency-mandated availability statements to indicate the public availability or distribution limitations of the report. If additional limitations/ restrictions or special markings are indicated, follow agency authorization procedures, e.g. RD/FRD, PROPIN, ITAR, etc. Include copyright information.

13. SUPPLEMENTARY NOTES. Enter information not included elsewhere such as: prepared in cooperation with; translation of; report supersedes; old edition number, etc.

14. ABSTRACT. A brief (approximately 200 words) factual summary of the most significant information.

15. SUBJECT TERMS. Key words or phrases identifying major concepts in the report.

16. SECURITY CLASSIFICATION. Enter security classification in accordance with security classification regulations, e.g. U, C, S, etc. If this form contains classified information, stamp classification level on the top and bottom of this page.

17. LIMITATION OF ABSTRACT. This block must be completed to assign a distribution limitation to the abstract. Enter UU (Unclassified Unlimited) or SAR (Same as Report). An entry in this block is necessary if the abstract is to be limited.
ANNUAL TECHNICAL (Oct15-Mar17) REPORT ON

AFOSR FA9550-15-1-0493

“Quantum Engineering of States in Heterostructure-based Detectors for Enhance
Performance --- Revision”

(1) Introduction

This research effort has the goals of exploiting and integrating forefront developments in nanoscience and nanoelectronics to conceive, design, fabricate, and test flexible sensors with greatly enhanced performance. To accomplish these goals, this effort focused on the design of novel heterostructure-based sensors that integrate multiple-quantum-well elements to yield enhanced performance based on quantum engineering of both electronic and phononic states. Specifically, in this work the unwanted thermally excited carrier contribution in these heterostructure-based photodetectors has been reduced by using phonon-assisted transitions to design structures having deeper initial quantum states. This novel design has been modeled and characterized experimentally for a prototypical heterostructure. In addition, this effort addressed the optimization of these photodetectors through tailoring carrier interactions in these reduced dimensional structures.

(2) List of Appendixes --- N/A

(3) Statement of Problem Studied

This research program addressed systematic theoretical and experimental investigations of nanostructure-based electronic and optoelectronic structures with the goal of facilitating major improvements in the performance levels of nanodevices beyond the current state-of-the-art. In particular, this program focuses on research thrusts with objectives including: model, design, fabricate, and experimentally characterize nano-device structures for enhanced charge transport & collection; model, design, fabricate, and experimentally characterize such nanodevices to optimize device structures with quantum-engineering and phonon-assisted transitions in nanostructures. Quantum engineering of nano-structures is emphasized. Related quantum-based structures – including those with spontaneous polarizations are included.

(4) Summary of Most Important Results

1

DISTRIBUTION A: Distribution approved for public release.
The most important results obtained during this period of this effort include: electrical and optical studies of components of devices and systems of quantum-dot-based optoelectronic devices; electronic and optical properties of quantum dots in ensembles; characterization of quantum-dot blinking phenomena; characterization of phonon modes in quantum dots; and extending a theory band formation in an array of colloidal quantum dots embedded in conductive polymer. Specific results were obtained on the following topics:

This research has focused on exploring the design and experimental verification of a concept for novel photodetectors with dramatic enhancement in detectivity, based on rapid interface phonon-assisted transitions combined with quantum engineering of phonon and electron states in nanostructures. Based on the concepts we introduced previously (Stroscio (1996), Kisin et al. (1997), Stroscio et al. 1999, and Stroscio and Dutta (2001) for heterostructure lasers, which have resulted in extremely large enhancements in the optical gain of quantum-well-based lasers, this work examines dramatic enhancement of photodetectivity in novel quantum-well based photodetectors in the first known embodiment that facilitates the detection of photons over a wide range of frequencies. In preliminary studies (Lan et al. (2014)), we have identified several different heterostructures for these photodetectors – with specific materials, compositions -- suitable as photodetectors incorporating phonon-assisted transitions: one based on GaAlAs/GaAs material system, one based on InGaAs/InAs material system and the other one base on InAlAs/InP material system. These designs bear similarities to phonon-assisted quantum cascade lasers discussed in papers (Spagnolo et al. (2002), Williams et al. (1999), Menon et al. (2002)) that make reference to our earlier treatments of phonons in heterostructures (Stroscio (1996), Kisin et al. (1997), and Stroscio et al. 1999).

In addition to interface phonon engineering, a novel feature of the designs considered herein is a double-well region that allows tuning of energy state differences so that a double resonance condition (Stroscio et al. (1999)) - for a pair of degenerate states and a pair of states separated by an interface phonon energy – can be satisfied. To our knowledge, this novel double-well system has not been used in conjunction with phonon-assisted transitions in the past; however, the double-well component is critical to the tunability of the low noise photodetectors advocated in this proposal. Herein, we consider a triple quantum-well structure with one single well and one double well; the relationship between the energy levels should be, as in Fig. 1.
Figure 1. Structure of single-well—double well heterostructure-based photodetector with intermediate states $E_3$ and $E_2$ that provide a channel for rapid phonon-assisted transitions of an electron from state $E_3$ to state $E_2$ as a result of the emission of an interface phonon.

From the energy level states in Figure 1, it follows that:

$$E_3 = E_2'$$

$$E_3 - E_1 = E_4' - E_2 = E_{\text{photon}}$$

And

$$E_2' - E_2 = E_{\text{phonon}}$$

The energy-level structure depicted in Figure 1 for the novel photodetector facilitates the absorption of a photon, emission of a phonon, and the absorption of a photon with the same wavelength as the original photon. $E_1$ is the first energy level of the single well, and $E_3$ is the second energy level. In addition, $E_2$, $E_2'$, $E_4$, and $E_4'$ represent the first, second, third, and forth energy levels for the double quantum well. With reference to the Figure 1, it is clear that there will be a dramatic signal-to-noise enhancement in the current, $I_{sn,E_1}$, from the deepest state $E_1$, relative to $I_{sn,E_2}$, from the deepest state $E_2$ (without phonon-assisted transition and second photon absorption), as given by the Richardson formula:
\[ \frac{I_{S1,E1}}{I_{S1,E2}} = e^{\frac{2E_{photon} - E_{phonon}}{kT}} = e^{\frac{E_{photon} - E_{phonon}}{kT}} \]

In this equation, \( E_3 - E_1 = E_4 - E_2 = E_{photon} \) and \( E_2' - E_2 = E_{phonon} \).

For example if,

\[ \frac{E_{photon} - E_{phonon}}{kT} = 8 \]

a dramatic 1/3,000 reduction in the noise is predicted. It is this reduction in noise through the quantum engineering of electronic and phononic states that is pursued in this research.

Based on the previous description, it is clear that this photodetector design exploits the use of rapid interface-phonon assisted electron transitions between the single quantum well (left) and and the double quantum well (right). In operation the photodetector works as follows: (1) a single photon is absorbed in the left single well; (2) the excited electron emits an interface phonon and, consequently, makes a transition to the double well on the right; (3) the electron then absorbs a photon and reaches the ionization limit where it is detected. The key innovations in this design are the tunable double-well structure coupled with the use of interface-phonon-assisted transitions so that the initial state of the electron is approximately twice as deep as in the case of a single-quantum well photodetector. This extra depth leads to a dramatic reduction in the unwanted thermal excitation from the initial state as estimated on the bottom right.

In this program a number of different heterostructure systems have been designed that facilitate phonon-assisted transitions in a single-well—double-well heterostructure with two pairs of energy levels having equal separations between eigenenergies for two-photon absorption.

After many calculations are made, one set of single-double well design parameter for GaAlAs material that optimizes the signal-to-noise in the photodetector is found as shown in Figure 2.
Figure 2. Result of signal-to-noise enhanced photodetector in Ga$_{1-x}$Al$_x$As material.

For the single well, Ga$_{0.452}$Al$_{0.548}$As is used as the barrier, and GaAs as the well. The potential of the single well then turns out to be 457.849 meV. For the double well, Ga$_{0.452}$Al$_{0.548}$As is still the barrier, both outside the double well and between it, and now we use Ga$_{0.741}$Al$_{0.259}$As as the well. A depth of 241.457 meV as potential of the double well is obtained.

In this result, we have the width of single well as 6 nm, and the width of each wells in double well as 6 nm as well. The barrier between the double well is 0.75 nm, and the barrier between single well and double well is 6 nm.

The energy states in single well then turns out to be $E_1 = 71.17$ meV, and $E_3 = 282.31$ meV. In the double well, energy states are $E_2 = 248.52$ meV, $E_2' = 282.52$ meV, $E_4 = 384.71$ meV, and $E_4' = 454.75$ meV as shown in Figure 2.

The whole process of this signal-to-noise photodetector in this design works as follows:

i. From the $E_1$ state, an electron absorbs one photon energy which equals to 211.19 meV, having wavelength of 5871.49 nm, and jumps to $E_3$ state.

ii. The electron emits one phonon energy of 33.79 meV, and falls down to the state $E_2$.

iii. Absorbing another photon with 206.23 meV (wavelength = 6012.70 nm) which having similar energy as the first one, the electron jumps to $E_4'$, which is very close to the barrier level of Ga$_{0.452}$Al$_{0.548}$As, and will be detected.
A range of light source which includes 5871.49 nm and 6012.70 nm will be detected by this detector.

For In$_{1-y}$Ga$_y$As, the need parameters must be specified; the parameters includes the discontinuity of conduction band energy for In$_{1-y}$Ga$_y$As that having different concentration of y, and its electron effective mass.

The total band gap energy discontinuity for In$_{1-x-y}$Al$_x$Ga$_y$As/AlAs is:

\[
\Delta V = [2.093x + 0.629y + 0.577x^2 + 0.436y^2 + 1.013xy - 2.0x^2(1 - x - y)] \text{ eV}
\]

and the band alignment is 47% of the total discontinuity in valence band, which means:

\[
\Delta V_{VB} = 0.47 \\
\Delta V_{CB} = 0.53
\]

The electron effective mass for In$_{1-x-y}$Al$_x$Ga$_y$As/AlAs is:

\[
m^* = (0.0427 + 0.0685x)m_0
\]

where \(m_0 = 9.10938215 \times 10^{-31}\).

Therefore, if \(x = 0\) is assumed in all the parameters, we can get parameters in In$_{1-y}$Ga$_y$As/AlAs follows:

\[
\Delta V' = (0.629y + 0.436y^2) \text{ eV}
\]

and since \(\Delta V_{VB} = 0.47\) and \(\Delta V_{CB} = 0.53\), the conduction band discontinuity of In$_{1-y}$Ga$_y$As/AlAs is:

\[
\Delta V'' = [(0.629y + 0.436y^2) \times 0.53] \text{ eV}
\]

Also,

\[
m'' = 0.0427m_0
\]

where \(m_0 = 9.10938215 \times 10^{-31}\).

Since Figure 3 illustrates the association of parameters of the In$_{1-y}$Ga$_y$As single-double well design and with different regions of the structure.
Figure 3. Single-double quantum well design in In$_{1-y}$Ga$_y$As material.

For the voltage level changing compared with InAs of wells and barriers in Figure 3, we have,

\[
V_1 = (0.629y_1 + 0.436y_1^2) \times 0.53
\]
\[
V_1 - V_2 = (0.629y_2 + 0.436y_2^2) \times 0.53
\]

and the corresponding electron effective mass are,

\[
m^*_1 = 0.0427m_0
\]
\[
m^*_2 = 0.0427m_0
\]

with \(m^*_{\text{InAs}} = 0.067m_0\).

The wave equations for the In$_{1-y}$Ga$_y$As single-double quantum well structure can now be described as follows:
\[
\begin{align*}
- \frac{\hbar^2}{2 \times 0.0427m_0} \frac{\partial^2}{\partial z^2} \varphi_1(z) + \left[\left(0.629y_1 + 0.436y_1^2\right) \times 0.53\right] \varphi_1(z) &= E \varphi_1(z) \\
& \quad \text{when } z \leq 0
\end{align*}
\]

\[
- \frac{\hbar^2}{2 \times 0.0427m_0} \frac{\partial^2}{\partial z^2} \varphi_2(z) = E \varphi_2(z)
\]

when \(0 \leq z \leq z_1\)

\[
- \frac{\hbar^2}{2 \times 0.0427m_0} \frac{\partial^2}{\partial z^2} \varphi_3(z) + \left[\left(0.629y_1 + 0.436y_1^2\right) \times 0.53\right] \varphi_3(z) = E \varphi_3(z)
\]

when \(z_1 \leq z \leq z_2\)

\[
- \frac{\hbar^2}{2 \times 0.0427m_0} \frac{\partial^2}{\partial z^2} \varphi_4(z) + \left[\left(0.629y_2 + 0.436y_2^2\right) \times 0.53\right] \varphi_4(z) = E \varphi_4(z)
\]

when \(z_2 \leq z \leq z_3\)

\[
- \frac{\hbar^2}{2 \times 0.0427m_0} \frac{\partial^2}{\partial z^2} \varphi_5(z) + \left[\left(0.629y_1 + 0.436y_1^2\right) \times 0.53\right] \varphi_5(z) = E \varphi_5(z)
\]

when \(z_3 \leq z \leq z_4\)

\[
- \frac{\hbar^2}{2 \times 0.0427m_0} \frac{\partial^2}{\partial z^2} \varphi_6(z) + \left[\left(0.629y_2 + 0.436y_2^2\right) \times 0.53\right] \varphi_6(z) = E \varphi_6(z)
\]

when \(z_4 \leq z \leq z_5\)

\[
- \frac{\hbar^2}{2 \times 0.0427m_0} \frac{\partial^2}{\partial z^2} \varphi_7(z) + \left[\left(0.629y_1 + 0.436y_1^2\right) \times 0.53\right] \varphi_7(z) = E \varphi_7(z)
\]

when \(z_5 \leq z\)

where \(\hbar = 1.054571628 \times 10^{-34}\), and \(m_0 = 9.10938215 \times 10^{-31}\).

Figure 4 illustrates the demands for signal-to-noise enhanced photodetector.

In In_{1-x}Ga_xAs design, the larger the y is, which means when the concentration of GaAs is higher, the higher the conduction band level will be.
Figure 4. Simulation for Single-Double Quantum Well in In$_{1-y_1}$Ga$_{y_1}$As material.

Figure 5. depicts the optimized structure for the design in InGaAs material based on many calculations performed by adjusting these parameters.
For the single well, $\text{In}_{0.248}\text{Ga}_{0.752}\text{As}$ is used as the barrier, and InAs as the well. The potential of the single well then turns out to be 381.371 meV. For the double well, $\text{In}_{0.248}\text{Ga}_{0.752}\text{As}$ is still the barrier, both outside the double well and between it, and now we use $\text{In}_{0.590}\text{Ga}_{0.410}\text{As}$ as the well. A depth of 205.845 meV as the potential of the double well is obtained.

In this result, we have the width of single well as 8.8 nm, and the width of each well in double well as 10 nm. The barrier between the double well is 0.6 nm, and the barrier between single well and double well is 10 nm.

The energy states in single well then turn out to be $E_1 = 61.614$ meV, and $E_3 = 232.18$ meV. In the double well, energy states are $E_2 = 198.28$ meV, $E_2' = 231.95$ meV, $E_4 = 307.54$ meV, and $E_4' = 375.68$ meV as shown in Figure 5.

The whole process for this signal-to-noise photodetector with InGaAs material in this design works as following:

i. From $E_1$ state, an electron absorbs one photon energy which equals to 170.57 meV, having wavelength of 7269.74 nm, and transitions to the $E_3$ state.

ii. The electron emits one phonon energy of 33.9 meV, with wavelength 36578.17 nm, and falls down to the state $E_2$.

iii. Absorbing another phonon with 177.4 meV (wavelength = 6989.85 nm) which having similar energy as the first one, the electron transitions to $E_4'$, which is very close to the barrier level of $\text{In}_{0.248}\text{Ga}_{0.752}\text{As}$, and will be detected.

The photon absorption for the first photon and the second photon having a difference of 4% in energy. Even though, error less than 5% is acceptable in experiment, the light source being detected needs to have a wide band at least from 6989.85 nm to 7269.74 nm in this apparatus.

The parameters we need include: the discontinuity of conduction band energy for $\text{In}_{1-x}\text{Al}_x\text{As}$ that having different concentration of x, the electron effective mass for the corresponding x value, and the conduction band energy level and electron effective mass of InP.

The total band gap energy discontinuity for $\text{In}_{1-x-y}\text{Al}_x\text{Ga}_y\text{As}/\text{AlAs}$ is mentioned in the previous part as:
\[ \Delta V = [2.093x + 0.629y + 0.577x^2 + 0.436y^2 + 1.013xy - 2.0x^2(1 - x - y)] \text{ eV} \]

and the band alignment is 47% of the total discontinuity in valence band, which means:

\[ \Delta V_{\text{VB}} = 0.47 \]
\[ \Delta V_{\text{CB}} = 0.53 \]

The electron effective mass for In\textsubscript{1-x-y}Al\textsubscript{x}Ga\textsubscript{y}As/AlAs is:

\[ m^* = (0.0427 + 0.0685x)m_0 \]

where \( m_0 = 9.10938215 \times 10^{-31} \).

Therefore, if \( y = 0 \) is assumed in all the parameters, we can get parameters for In\textsubscript{1-x}Al\textsubscript{x}As/AlAs as follows:

The total band discontinuity is:

\[ \Delta V' = (2.093x - 1.423x^2 + 2x^3) \text{ eV} \]

and since that \( \Delta V_{\text{VB}} = 0.47 \) and \( \Delta V_{\text{CB}} = 0.53 \), the conduction band discontinuity of In\textsubscript{1-y}Ga\textsubscript{y}As/AlAs is:

\[ \Delta V'' = [(2.093x - 1.423x^2 + 2x^3) \times 0.53] \text{ eV} \]

Also,

\[ m''^* = (0.0427 + 0.0685x)m_0 \]

where \( m_0 = 9.10938215 \times 10^{-31} \).

The heterointerface in the InGaAs/InAlAs/InP family is described as follows:

For the conduction band energy level, In\textsubscript{0.52}Al\textsubscript{0.48}As is 0.34 eV higher than InP.

The conduction band discontinuity of In\textsubscript{0.52}Al\textsubscript{0.48}As to AlAs is 0.475921 eV.
The conduction band discontinuity of InAs to AlAs is 1.4151 eV.

Figure 6 depicts the relevant energy conditions.
Figure 6. Conduction band energy level relationships of the \( \text{In}_{0.52}\text{Al}_{0.48}\text{As}/\text{InAs}/\text{AlAs}/\text{InP} \) family.

As shown in Figure 6, we can calculate the conduction band discontinuity of \( \text{InP} \) to \( \text{AlAs} \) by substrate 0.475921 eV to 0.34 eV, so 0.135921 is obtained.

For the conduction band discontinuity of \( \text{InAs} \) to \( \text{InP} \): 1.4151 eV − 0.135921 eV = 1.279179 eV, which is the largest quantum well potential that we are able to design in \( \text{InAlAs/InP} \) design when using \( \text{InP} \) as the material of the single well.

For calculating the \( \text{In}_{1-x}\text{Al}_x\text{As}/\text{InP} \) conduction band discontinuity, the relationship of them is plotted as Figure 7.
According to Figure 7, 

\[
\Delta V''' = (\Delta V'' - 0.135921) \text{ eV} \\
= [(2.093x - 1.423x^2 + 2x^3) \times 0.53 - 0.135921] \text{ eV}
\]

Using the previously-defined parameters the single-double well design in In\(_{1-x}\)Al\(_x\)As/InP material is defined as illustrated in Fig. 8.
Figure 8. Single-Double Quantum Well Design in In$_{1-x}$Al$_x$As/InP material.

For the conduction band (CB) changes compared with InP conduction band is depicted in Figure 8 for the structure made consideration.

The value of $V_1$ and $V_2$ in Figure 14 are given in terms of:

$$V_1 = [(2.093x_1 - 1.423x_1^2 + 2x_1^3) \times 0.53 - 0.135921]$$

$$V_1 - V_2 = [(2.093x_2 - 1.423x_2^2 + 2x_2^3) \times 0.53 - 0.135921]$$

The corresponding electron effective masses are,

$$m_1^* = (0.0427 + 0.0685x_1)m_0$$

$$m_2^* = (0.0427 + 0.0685x_1)m_0$$

as well as $m_{InP}^* = 0.08m_0$.

The Schrödinger equations for solutions, as outlined previously, yield the following designs.

In the In$_{1-x}$Al$_x$As/InP design, the larger the $x$ is, the higher the conduction band level will be.
These results illustrate the feasibility of the phonon-assisted photodetector design in a variety of heterostructure systems.

The AlGaAs/GaAs triple quantum well photodetector (QWP) with a detection wavelength at 5 μm has been analyzed further as discussed in Tang et al. (2016) which was produced under this grant. It shows that the escape probability of phonon-assisted tunneling devices can be enhanced by over two times, if the condition of the electron-phonon resonance is accompanied by the anticrossing between first excited level in single QW and the first excited level in the adjacent double QW. The escape probability in the proposed triple QWP is optimized to be as high as 0.8, which is at least two times higher than reported in QCDs. In addition, the noise current in the proposed structure is studied to have a reduction of $2.9 \times 10^{13}$ times that in a QWP at 77 K. Moreover, the effects of delta doping locations and densities on scattering time and absorption coefficient in AlGaAs/GaAs triple QWP have been studied theoretically. It shows that delta doping at the middle of the single well has advantages in obtaining longer intersubband relaxation time, larger escape probability and higher absorption coefficient. These results are especially valuable for designing double resonance optoelectronic device.

A summary of results obtained during this effort include: design of novel multi-quantum-well structures with greatly enhanced signal-to-noise in tailored structures that
employ phonon-assisted transition to enhance the effective ionization potential; spontaneous polarization induced electric field in zinc oxide nanowires and nanostars; and enhanced optical properties due to indium incorporation in zinc oxide nanowires.

Summary: Specific results were obtained on the following topics: phononic properties for enhanced signal-to-noise photodetector; spontaneous polarization induced electric field in nanostructures; AlGaAs/GaAs triple well photodetector design based on phonon-assisted transitions operating at a 5-micron wavelength with greatly reduced noise – noise reduced several orders of magnitude at room temperature; and enhanced optical properties due to indium incorporation in zinc oxide nanowires.

DISTRIBUTION A: Distribution approved for public release.
(7) Honors and Awards

The PI was:

Appointed as a University Distinguished Professor (2015); typically 3 or 4 UIC professors are selected each year.

Reappointed as the Richard and Loan Hill Professor (2017)

Award for Excellence in Teaching (2017) - typically 3 or 4 UIC professors are selected each year. This is UIC’s highest teaching award.

Elected to the College of Fellows, American Institute of Medical and Biomedical Engineers

### Abstract

This research effort has the goals of exploiting and integrating forefront developments in nanoscience and nanoelectronics to conceive, design, fabricate, and test flexible sensors with greatly enhanced performance. To accomplish these goals, this effort focused on the design of novel heterostructure-based sensors that integrate multiple-quantum-well elements to yield enhanced performance based on quantum engineering of both electronic and phononic states. Specifically, in this work the unwanted thermally excited carrier contribution in these heterostructure-based photodetectors has been reduced by using phonon-assisted transitions to design structures having deeper initial quantum states. This novel design has been modeled and characterized experimentally for a prototypical heterostructure. In addition, this effort addressed the optimization of these photodetectors through tailoring carrier interactions in these reduced dimensional structures. This research program addressed systematic theoretical and experimental investigations of nanostructure-based electronic and optoelectronic systems. 

*DISTRIBUTION A: Distribution approved for public release.*
structures with the goal of facilitating major improvements in the performance levels of nanodevices beyond the current state-of-the-art. In particular, this program focuses on research thrusts with objectives including: model, design, fabricate, and experimentally characterize nano-device structures for enhanced charge transport & collection; model, design, fabricate, and experimentally characterize such nanodevices to optimize device structures with quantum-engineering and phonon-assisted transitions in nanostructures. Quantum engineering of nano-structures is emphasized. Related quantum-based structures – including those with spontaneous polarizations are included.

Distribution Statement
This is block 12 on the SF298 form.
Distribution A - Approved for Public Release

Explanation for Distribution Statement
If this is not approved for public release, please provide a short explanation. E.g., contains proprietary information.

SF298 Form
Please attach your SF298 form. A blank SF298 can be found here. Please do not password protect or secure the PDF. The maximum file size for an SF298 is 50MB.
