ABSTRACT

A method is developed for calculating the growth of a turbulent boundary layer at hypersonic Mach numbers. Excellent agreement with experimental results from axisymmetric nozzles has been obtained by the application of this method. The method utilizes a modification of Stewartson's transformation to simplify the integration of the momentum equation. Heat transfer is taken into account by evaluating the gas properties at Eckert's reference temperature and by using a modification of Crocco's quadratic for the temperature distribution in the boundary layer. A new empirical relation is used for the incompressible friction coefficient which agrees with experimental data over a Reynolds number range from $10^5$ to $10^9$.

NOMENCLATURE

A Flow area
a Speed of sound
$C_f$ Local skin-friction coefficient
$C_F$ Mean skin-friction coefficient
h Enthalpy
H Boundary layer form factor
M Mach number
N Parameter in power-law equations for skin friction
P Function defined in Eq. (4)
p Pressure
Q Function defined in Eq. (4)
$R^*$ Radius of curvature of nozzle at the throat
$R_x$ Reynolds number based on $x$

INTRODUCTION

Many investigators have studied the problem of calculating the growth of turbulent boundary layers. For the incompressible adiabatic case, such calculations are fairly straightforward since they depend only upon the empirical relationship of the skin-friction coefficient with Reynolds number when the pressure gradients in the direction of flow are favorable or absent (Ref. 1). Even in the presence of adverse pressure gradients, empirical methods have been devised for the purpose of predicting the location of separation (Ref. 2).

As the speed of the gas outside the boundary layer increases, the effects of compressibility on the skin-friction coefficient must also be taken into account. For many cases in supersonic flow, the heat transfer between the gas and the wall may be neglected and methods such as Tucker's (Ref. 3) may be used to calculate the boundary-layer growth. There is enough difference, however, between the free-stream static temperature and the adiabatic wall temperature that some intermediate "reference" temperature must be used for evaluating the compressible skin-friction coefficient in order to obtain good correlation with experimental results. Tucker uses a reference temperature equal to the arithmetic average of the adiabatic wall temperature and the free-stream static temperature.

For gases with a Prandtl number of 1, the adiabatic wall temperature is equal to the stagnation temperature and the thermal boundary layer has the same thickness as the velocity boundary layer. For gases such as air which have a Prandtl number less than 1, the adiabatic wall temperature is less than the stagnation temperature and the thermal boundary layer is thicker than the velocity boundary layer. Bartz (Ref. 4) attempts to take this effect into account, together with the effect of heat transfer, by obtaining simultaneous solutions of the momentum equation and the energy equation. He, however, restricts his solution to a one-seventh-power velocity profile and uses a reference temperature equal to the arithmetic average of the wall temperature and the free-stream static temperature.

When the wall temperature is much lower than the adiabatic wall temperature (often the situation at hypersonic speeds), the reference temperature should be somewhat higher than the arithmetic mean between the wall and free-stream static temperature as shown by Sommer and Short (Ref. 5) and Tendeland (Ref. 6). The reference temperature suggested by Eckert (Ref. 7) correlates with existing data as well as that used by Sommer and Short. Persh (Ref. 8)
attempts to account for this same effect by using a reference temperature equal to the temperature at the edge of the laminar sub-layer, where this temperature is defined as a function of velocity ratio according to Crocco's quadratic modified by using the adiabatic wall temperature to account for the Prandtl number being less than one.

One important use of an accurate method of calculating turbulent-boundary-layer growth at hypersonic Mach numbers is in the design of axisymmetric hypersonic wind tunnels. The perfect-fluid (potential-flow) contour can be accurately calculated by the method of characteristics, but the attainment of uniform flow in the test region depends also upon the accuracy of the boundary-layer correction to the theoretical contour. Each of the available methods of calculating boundary-layer growth possessed some drawback. This fact led to the development of the method described herein, which utilizes a modification of Stewartson's transformation (Ref. 9) to aid in the integration of the momentum equation. The main difference, however, between this method and other methods is in the evaluation of the compressible skin-friction coefficient and the transformed form factor. In order to simplify the calculations, a new empirical equation was developed for the incompressible skin-friction coefficient which agrees with experimental data over a range of Reynolds number \( \left( R_{x_t} \right) \) from \( 10^6 \) to \( 10^7 \). Excellent correlations have been obtained between experimental values of boundary-layer displacement thickness and those calculated by this method.

Since this method was developed primarily for hypersonic wind tunnels, it may not be suitable where adverse pressure gradients are present or where the temperatures are sufficiently high to cause dissociation.

DEVELOPMENT OF METHOD

MOMENTUM EQUATION

For the purpose of this report, steady compressible flow is assumed. Thus, the von Karman momentum equation for axisymmetric flow can be written in the form:

\[
\frac{d\theta}{ds} + \theta \left[ \frac{2 - M^2 + \frac{H}{\gamma - 1} M^2}{M \left( 1 + \frac{1}{2} M^2 \right)} \frac{dM}{ds} + \frac{1}{r} \frac{dr}{ds} \right] = \frac{C_t}{2}
\]  

(1)

In order to obtain a solution for the momentum thickness \( \theta \), the values of \( M, H, r, \) and \( C_t \) must be known as a function of distance \( s \) along the surface. For many cases, such as wind tunnel nozzles, these values are known as a function of distance \( x \) along the center line. Since
\[
\frac{ds}{dx} = \sqrt{1 + \left(\frac{dr}{dx}\right)^2} = \sec \omega \tag{2}
\]

Eq. (1) may be written as

\[
\frac{d\theta}{dx} + \theta \left[ \frac{2 - M^2 + H}{M \left(1 + \frac{\gamma - 1}{2} M^2 \right)} \frac{dM}{dx} + \frac{1}{r} \frac{dr}{dx} \right] = \frac{C_f}{2} \sec \omega \tag{3}
\]

When \( \omega \) is small, the assumption that \( \sec \omega = 1 \) can be made with negligible consequences.

It can be recognized that Eq. (3) is a linear, first-order, ordinary differential equation of the form

\[
\frac{d\theta}{dx} + \theta \, P(x) = Q(x) \tag{4}
\]

which has the solution

\[
\theta (x) = e^{-\int P \, dx} \left[ \int Q(x) e^{\int P \, dx} \, dx + \text{constant} \right] \tag{5}
\]

Since \( P(x) \) and \( Q(x) \) are generally non-analytic functions of \( x \), numerical methods must be used to evaluate the indicated integrations.

The solution of Eq. (3) is considerably simplified, however, through the use of the equations

\[
\theta = \theta_{tr} \left( 1 + \frac{\gamma - 1}{2} M^2 \right)^{\frac{\gamma + 1}{2(\gamma - 1)}} = \theta_{tr} \left( \frac{T_o}{T_e} \right)^{\frac{\gamma + 1}{2(\gamma - 1)}} \tag{6}
\]

and

\[
H = H_{tr} \left( 1 + \frac{\gamma - 1}{2} M^2 \right) + \frac{\gamma - 1}{2} M^2 \tag{7a}
\]

or

\[
H + 1 = (H_{tr} + 1) \frac{T_o}{T_e} \tag{7b}
\]

which are obtained from Stewartson's transformation as shown in Appendix A. By substituting Eq. (6) and (7) into Eq. (3), the equation

\[
\frac{d\theta_{tr}}{dx} + \frac{\theta_{tr}}{M} \frac{dM}{dx} (2 + H_{tr}) + \frac{\theta_{tr}}{r} \frac{dr}{dx} = \frac{C_f}{2} \sec \omega \left( \frac{T_e}{T_o} \right)^{\frac{\gamma + 1}{2(\gamma - 1)}} \tag{8}
\]
is obtained. By multiplying Eq. (8) by \( r M^2 + H_{tr} \), the left-hand side becomes a perfect differential if \( H_{tr} \) is assumed to be constant over the interval of integration. Therefore,

\[
\left( \theta_{tr} r M^2 + H_{tr} \right)_b - \left( \theta_{tr} r M^2 + H_{tr} \right)_a = \int_a^b \left[ \frac{C_l}{2} \left( \frac{T_e}{T_o} \right)^{\frac{y+1}{2(y-1)}} \right] \, dx
\]  

(9)

Thus, the solution of the momentum equation is reduced to a single integration which, in general, must be accomplished by numerical methods.

Substitution of Eq. (6) into Eq. (9) yields

\[
\left[ \theta r M^2 + H_{tr} \left( \frac{T_e}{T_o} \right)^{\frac{y+1}{2(y-1)}} \right]_b - \left[ \theta r M^2 + H_{tr} \left( \frac{T_e}{T_o} \right)^{\frac{y+1}{2(y-1)}} \right]_a = \int_a^b \left[ \frac{C_l}{2} \left( \frac{T_e}{T_o} \right)^{\frac{y+1}{2(y-1)}} \right] \, dx
\]

(10)

It may be noted that, as long as \( H_{tr} \) as defined by Eq. (7) is approximately constant, Eq. (6) and (7) may be considered to be merely integrating aids irrespective of the validity of Stewartson's transformation.

When there is no heat transfer and the Prandtl number is one, the transformed form factor becomes equal to the incompressible value. In an attempt to account for heat transfer and for Prandtl numbers other than one, use is made of Crocco's quadratic for the temperature distribution in the boundary layer according to the equation

\[
\frac{T}{T_e} = \frac{T_w}{T_e} - \left( \frac{T_w - T_{aw}}{T_e} \right) \left( \frac{u}{u_e} \right) - \left( \frac{T_{aw} - T_e}{T_e} \right) \left( \frac{u}{u_e} \right)^2
\]

(11)

which is the form used by Persh (Ref. 8). As shown in Appendix A, the use of this equation yields

\[
II = II_i \left( \frac{T_w}{T_e} \right) + \left( \frac{T_{aw} - T_e}{T_e} \right)
\]

(12)

Combining Eqs. (7) and (12) gives

\[
II_{tr} = II_i \left( \frac{T_w}{T_o} + \frac{T_{aw} - T_o}{T_o} - 1 \right)
\]

(13)

which relates the transformed form factor in terms of the incompressible value and the temperature ratios.
For the evaluation of Eq. (1) for a particular problem, values of r, M, ω, and γ are given as functions of x. With the wall temperature given or assumed as a function of x, Hₜᵣ may be found by Eq. (13) in terms of Hᵢ. Still remaining to be determined are Cᵢ and Hᵢ, which are considered in subsequent sections.

DETERMINATION OF Cᵢ

The compressible skin-friction coefficient Cᵢ in Eq. (10) is a function of Mach number, Reynolds number, and heat transfer and is defined in terms of the shearing stress at the wall,

$$\frac{Cᵢ}{2} = \frac{τᵢ}{ρₑ uₑ^2}$$  \hspace{1cm} (14)

In the evaluation of Cᵢ, efforts are made to obtain empirical correlations with the incompressible value which is a function of Reynolds number based either on the momentum thickness or distance,

$$\frac{Cᵢ}{2} = \frac{τᵢ}{ρₑ uₑ^2} = F (Rθᵣ) = G (Rₓᵣ)$$  \hspace{1cm} (15)

The assumption has been made that there is some reference point in the compressible boundary layer where the temperature and density are such that

$$\frac{Cᵢ'}{2} = \frac{τᵢ'}{ρₑ uₑ^2} = F (Rθ'ᵣ) = G (Rₓ'ᵣ)$$  \hspace{1cm} (16)

where

$$Rθ'ᵣ = \frac{ρ' uₑ}{μ'}$$  \hspace{1cm} (17)

$$Rₓ'ᵣ = \frac{ρ' uₓ x}{μ'}$$  \hspace{1cm} (18)

and the values of ρ' and μ' are evaluated at the reference temperature. Therefore,

$$\frac{Cᵢ}{2} = \frac{Cᵢ'}{2} = \frac{Tₑ}{T'} F (Rθ'ᵣ) = \frac{Tₑ}{T'} G (Rₓ'ᵣ)$$  \hspace{1cm} (19)

since the pressure is assumed to be constant through the boundary layer.

It may be shown, however, that

$$\frac{Tₑ}{T'} F (Rθ'ᵣ) \neq \frac{Tₑ}{T'} G (Rₓ'ᵣ)$$
by using the power-law equations for skin-friction coefficient

\[ F(R\theta') = \frac{a}{(R\theta')^{\frac{1}{N}}} \]  (20)

and

\[ G(R_x \cdot') = \frac{\beta}{(R_x \cdot')^{\frac{1}{N+1}}} \]  (21)

where

\[ \beta = \frac{\frac{\mu'^{\lambda}}{\rho'^{\lambda} / \mu^{\lambda}}}{(N+1)^{\frac{1}{N+1}}} \]  (22)

can be derived from the incompressible relationships. In the absence of pressure gradient, Eq. (1) can be written as

\[ \frac{d\theta}{dx} = \frac{C_f}{2} \]  (23)

If

\[ \frac{C_f}{2} = \frac{T_e}{T'} F(R\theta') = \frac{T_e}{T'} \frac{a}{\left(\frac{\rho'^{\lambda}}{\mu'^{\lambda}} \right)^{\frac{1}{N}}} \]  (24)

then

\[ \theta^{\frac{1}{N}} d\theta = \left(\frac{T_e}{T'}\right) a \left(\frac{\rho'^{\lambda}}{\mu'^{\lambda}}\right)^{\frac{1}{N}} d\theta \]  (25)

and, after integrating,

\[ \frac{C_F}{2} = \frac{\theta}{x} = \left(\frac{T_e}{T'}\right)^N \frac{N+1}{N} a \frac{\alpha}{(R_x \cdot')^{\frac{1}{N+1}}} \]  (26)

On the other hand, if

\[ \frac{C_f}{2} = \frac{T_e}{T'} G(R_x \cdot') = \frac{T_e}{T'} \frac{\beta}{\left(\frac{\rho'^{\lambda}}{\mu^{\lambda}} / \mu^{\lambda}\right)^{\frac{1}{N+1}}} \]  (27)
then

\[ d\theta = \frac{T_e}{T'} \beta \left( \frac{\mu'}{\rho' u_e} \right)^{\frac{1}{N + 1}} \frac{dx}{x^{\frac{1}{N + 1}}} \]  

(28)

and, after integrating,

\[ \frac{C_F}{2} = \frac{\theta}{x} = \frac{T_e}{T'} \left( \frac{N + 1}{N} \beta \right)^{\frac{1}{N + 1}} = \frac{T_e}{T'} \left( \frac{N + 1}{N} \alpha \right)^{\frac{N}{N + 1}} \]  

(29)

It is obvious that Eq. (26) is not equal to Eq. (29), and therefore Eq. (24) and Eq. (27) cannot both be correct. Experimental correlation must be made to determine which equation gives the better results.

The determination of the proper value of reference temperature to be used must also depend upon experimental correlation. Eckert (Ref. 7) suggests the relation

\[ T' = 0.5 T_w + 0.22 T_{aw} + 0.28 T_e \]  

(30)

which, if the recovery factor is equal to 0.896, becomes

\[ T' = 0.5 T_w + (0.5 + 0.039) T_e \]  

(31)

Sommer and Short (Ref. 5) suggest the relation

\[ T' = 0.45 T_w + (0.55 + 0.035) T_e \]  

(32)

which, again if the recovery factor is equal to 0.896, becomes

\[ T' = 0.45 T_w + 0.195 T_{aw} + 0.355 T_e \]  

(33)

Eckert’s relation shows slightly greater effects of both heat transfer and Mach number than does that of Sommer and Short and appears to give slightly better correlation with the meager amount of data which exists at hypersonic Mach numbers. In order to take into account the effects of variable specific heat, Eckert suggests the use of a reference enthalpy

\[ h' = 0.5 h_w + 0.22 h_{aw} + 0.28 h_e \]  

(34)

for evaluating the physical properties of the gas. Although the derivations described herein are developed for constant specific heat, this modification can be easily substituted throughout.
The correlation of theoretical results with experimental data can be made by comparing the ratios of compressible skin-friction coefficients to the incompressible value at the same free-stream Reynolds number. Most of the experimental data have been obtained in wind tunnels. In the supersonic range up to a Mach number of about 5, stagnation temperatures are of the order of 100°F or 560° R while the static temperatures decrease with increasing Mach number until a value of about 100° R is reached. At higher Mach numbers, the stagnation temperature is increased to maintain the static temperature at about 100° R in order to avoid liquefaction of the constituents of the air. The temperature variation which is suggested for correlating wind tunnel results is shown in Fig. 1 along with Eckert's reference temperature for the adiabatic wall condition. The temperature range is so great that a simple power law for the variation of viscosity with temperature is not valid, and Sutherland's law must be used above 198.7° R. Below this temperature, there is some meager evidence that the viscosity varies proportionally with the temperature (the curve is tangent to the Sutherland curve). Misleading results can be obtained if such factors are not taken into account for correlation over a wide range in Mach numbers.

A correlation of \( C_f/C_{f_i} \) as a function of Mach number is shown in Fig. 2. The experimental data were taken from Refs. 10 through 17 and are for approximately adiabatic wall conditions. The values of \( C_{f_i} \) used for the ratios were obtained from the relation

\[
C_{f_i} = \frac{0.088 \left( \log R_{xx_i} - 2.3686 \right)}{\left( \log R_{xx_i} - 1.5 \right)^{1/2}}
\]

which is developed in Appendix B. The values of \( C_f \) were obtained from the relation

\[
C_f = \frac{T_e}{T'} \frac{0.088 \left( \log R_{xx'} - 2.3686 \right)}{\left( \log R_{xx'} - 1.5 \right)^{1/2}}
\]

where

\[
R_{xx'} = \frac{\rho' u_x x}{\mu'} = \frac{T_e \mu_x}{T' \mu'} R_x
\]

and \( R_x \), the free-stream Reynolds number, is the same as \( R_{xx_i} \) for this curve. The static and reference temperatures from Fig. 1 were used to obtain the ratio of \( C_f/C_{f_i} \) shown in Fig. 2. The good correlation shown indicates that Eq. (36) provides an adequate method of determining \( C_f \) for use in Eq. (10). It should be noted that Eq. (36) is of the general form of Eq. (27) which therefore represents experimental results better than Eq. (24).
Much of the experimental data is available in terms of $R_0$. The corresponding value of $R_x$ can be found from Eq. (36) in the same manner in which Eq. (29) was obtained from Eq. (27).

$$\theta = \int_0^x \frac{T_x}{T} \left( \frac{0.044}{(1.5)} \right) \, dx \quad (38)$$

After integration

$$\frac{C_F}{x} = \frac{\theta}{\bar{R}} = \frac{R_0}{R_x} \left( \frac{0.044}{(1.5)} \right) \quad (39)$$

Therefore

$$R_0 = \frac{\mu_T}{\mu} \left( \frac{0.044 R_x}{(1.5)} \right) \quad (40)$$

From this equation, the determination of $R_0$ is straightforward when $R_x$ is given; however, when $R_0$ is given, $R_x$ must be found by some iterative method such as Newton's. In a similar manner,

$$R_0 = \frac{0.044 R_x}{(1.5)} \quad (41)$$

Once $R_x$ and $R_{x,i}$ are found to satisfy Eqs. (40) and (41), $C_f$ and $C_{f,i}$ can be found from Eqs. (36) and (35) for $R_0 = R_{0,i}$ and a new ratio of $C_f/C_{f,i}$ can be determined. Such a ratio is shown in Fig. 3 along with experimental data from Refs. 10, 11, 18, 19, and 20. Again, good correlation is shown, indicating that Eq. (36) is satisfactory for the determination of $C_f$.

DETERMINATION OF $H_i$

As shown previously by Eq. (13), the transformed form factor can be expressed in terms of the incompressible, adiabatic form factor and temperature ratios. It is further shown in Appendix B that $H_i$ is related to $C_{f,i}$ by

$$H_i = \frac{1}{1 - \frac{1}{\sqrt{C_{f,i}/2}}} \quad (42)$$

and is, therefore, a function of the incompressible Reynolds number. Thus, there remains the problem of determining the relation between the compressible and incompressible Reynolds number.

In the transformation of Eq. (3) into Eq. (8) by means of Eq. (6) and (7), no transformation of $x$ was involved. However, Eq. (8) can be written as
where $U_e$ is the transformed velocity (Appendix A) and the transformation $dx/dX$ must be defined. For incompressible flow, the momentum equation can be written as

$$
\frac{d \theta_i}{dx_i} + \frac{\theta_i}{u_{e_i}} \frac{du_{e_i}}{dx_i} (2 + H_i) + \frac{\theta_i}{r} \frac{dr}{dx_i} = \frac{C_{f_i}}{C_{f_i}} \sec \omega \left( \frac{T_e}{T_o} \right)^{Y + 1} (Y - 1) \frac{dx}{dX} + \frac{C_{f_i}}{2} \sec \omega
$$

with fluid properties $\rho_o$ and $\mu_o$ evaluated at $T_o$. Comparison of these equations indicates that the transformed flow may be considered incompressible if

$$
\frac{d X}{d x} = \frac{C_{f_i}}{C_{f_i}} \left( \frac{T_e}{T_o} \right)^{Y + 1} (Y - 1) \frac{dx}{dX} + \frac{C_{f_i}}{2} \sec \omega
$$

where $C_{f_i}$ is obtained as a function of Reynolds number based on $x$ and $C_{f_i}$ is obtained as a function of $R_X = \rho_o U_e X / \mu_o$.

The original Stewartson's transformation used the relation

$$
\frac{d X}{d x} = \left( \frac{T_e}{T_o} \right)^{3Y - 1} (Y - 1) \frac{dx}{dX} + \left( \frac{T_e}{T_o} \right)^{4} \text{ for } Y = 1.4
$$

Culick and Hill (Ref. 21) using the stagnation temperature as a reference temperature obtained the relation

$$
\frac{d X}{d x} = \left( \frac{T_e}{T_o} \right)^{Y + 1} (Y - 1) \frac{N - 1}{N} \left( \frac{T_e}{T_o} \right)^{4} \text{ for } Y = 1.4
$$

Mager (Ref. 22) using a still different approach obtained the relation

$$
\frac{d X}{d x} = \frac{\mu_e}{\mu_o} \left( \frac{T_e}{T_o} \right)^{Y + 1} (Y - 1) \frac{dx}{dX} + \frac{\mu_e}{\mu_o} \left( \frac{T_e}{T_o} \right)^{4} \text{ for } Y = 1.4
$$

which reduces to Stewartson's transformation if the viscosity is assumed proportional to the temperature.

If Eqs. (35) and (36) are substituted into Eq. (45), the result is, since $R_X = R_s i$

$$
\frac{\mu_o}{\rho_o U_o} \frac{(\log R_X - 2.3686)}{(\log R_X - 1.5)^3} dR_X = \left( \frac{T_e}{T_o} \right)^{Y + 1} (Y - 1) \frac{dx}{dX} + \frac{\mu_e}{\rho u_o} dR_x
$$

16
which, after integrating, yields

\[
\frac{\rho_o R_X}{\rho_o u_e (\log R_X - 1.5)^2} = \left( \frac{T_e}{T_o} \right)^{\frac{\gamma + 1}{2(\gamma - 1)}} \frac{T_e'}{T'} \frac{\mu' R_x'}{\rho' u_e (\log R_x' - 1.5)^2}
\]

(50)

Since

\[
\frac{u_e}{u_e} = \left( \frac{T_o}{T_e} \right)^{\frac{1}{\gamma - 1}}, \quad \frac{\rho_o}{\rho_e} = \left( \frac{T_o}{T_e} \right)^{-\frac{1}{\gamma - 1}} \quad \text{and} \quad \frac{\rho e}{\rho} = \frac{T'}{T_e}
\]

Eq. (50) reduces to

\[
\frac{R_X}{(\log R_X - 1.5)^2} = \frac{\mu'}{\mu_o} \frac{R_x'}{(\log R_x' - 1.5)^2}
\]

(51)

which relates the incompressible Reynolds number to the reference Reynolds number. Eq. (51) cannot be solved directly for \(R_X\), but the use of Newton's approximation with \(R_X = (\mu' / \mu_o) R_x'\) as the first approximation yields as a second approximation

\[
R_X = \frac{\mu' R_x'}{\mu_o} \frac{1}{(\log \frac{\mu' R_x'}{\mu_o} - 2.3686) ^{\frac{1}{2}}} \left[ (\log \frac{\mu' R_x'}{\mu_o} - 1.5)^{\frac{1}{2}} - 0.8686 \right]
\]

(52)

which is sufficiently accurate to determine \(C_l\) from Eq. (35). This value of \(C_l\) is then used in Eq. (42) to determine \(H_{zz}\), after which \(H_{tr}\) can be found from Eq. (13) for use in integrating Eq. (10).

APPLICATION TO AXISYMMETRIC TUNNELS

In the application of Eq. (10) to calculate the boundary layer growth of an axisymmetric wind tunnel, the calculations are usually begun at the throat where the Mach number is unity. Equation (10) can thus be written

\[
\left[ \theta \frac{r}{r^*} \left( \frac{T_e}{T_o} \right)^{\frac{\gamma + 1}{2(\gamma - 1)}} M^{2 + H_{tr}} \right] = \theta^* \left( \frac{T_{e'}^*}{T_{o'}^*} \right)^{\frac{\gamma + 1}{2(\gamma - 1)}}
\]

\[
+ \int_{x_{zz}}^x \frac{r}{r^*} \left( \frac{T_e}{T_o} \right)^{\frac{\gamma + 1}{2(\gamma - 1)}} M^{2 + H_{tr}} \frac{C_l}{2} \sec \omega \, dx
\]

(53)
In many cases, the momentum thickness at the throat $\theta^*$ can be assumed to be equal to zero without appreciably affecting the values calculated near the end of the nozzle.

The Reynolds number at the throat must be based upon a value of $x$ which is other than zero in order to start with a finite value of $C_T$. A useful approximation for this initial value of $x^*$ can be obtained in the manner suggested by Sibulkin in Ref. 23. The velocity gradient at the throat is obtained in terms of the radius of curvature at the throat:

$$\left[ \frac{du_x}{dx} \right]_{M = 1} = \frac{a_o}{\sqrt{\frac{y + 1}{2}} \frac{r^*}{R^*}}$$

It is then assumed that the velocity gradient is constant from zero to the throat so that

$$\left[ \frac{u_x}{x^*} \right]_{M = 1} = \frac{a_o}{\sqrt{\frac{y + 1}{2} \frac{x^*}{x}}} = \left[ \frac{du_x}{dx} \right]_{M = 1}$$

Therefore,

$$x^* = \sqrt{\frac{y + 1}{2} \frac{r^*}{R^*}}$$

The Reynolds number at each point along the nozzle is thus based upon a value of $x$ equal to $x^*$ plus the distance from the throat to the point.

In general, the distance $s$ along the nozzle contour may be assumed to be equal to the distance $x$ along the axis for the purpose of determining the Reynolds number.

The above approximation can also be used to estimate the momentum thickness at the throat with the additional assumption that the values of the reference temperature and the reference Reynolds number are constant and equal to the values at the throat. Equation (10) may then be written

$$\theta^* \left( \frac{T_e^*}{T_o} \right)^{\frac{y+1}{2(y-1)}} = T_o \left( \frac{T_e^*}{T_o} \right)^{\frac{y+1}{2(y-1)}} \int_a^1 \left( \frac{T_e^*}{T_o} \right)^{\frac{y+1}{2(y-1)}} \frac{1}{R^*} \frac{M^2 + 2}{du_x/dx} \frac{M^2}{dM} dM$$

Since

$$\frac{r}{r^*} = \left[ \frac{1 + \frac{y-1}{2} M^2}{\frac{y+1}{2}} \right] \frac{M^2}{dM}$$

Equation (57) may then be written

$$\theta^* \left( \frac{T_e^*}{T_o} \right)^{\frac{y+1}{2(y-1)}} = T_o \left( \frac{T_e^*}{T_o} \right)^{\frac{y+1}{2(y-1)}} \int_a^1 \left( \frac{T_e^*}{T_o} \right)^{\frac{y+1}{2(y-1)}} \frac{1}{R^*} \frac{M^2 + 2}{du_x/dx} \frac{M^2}{dM} dM$$
and

\[ \frac{du_e}{dM} = \frac{n_o}{(1 + \frac{\gamma - 1}{2} M^2)^{3/2}} \]  

(59)

thus, after substitution and rearranging,

\[ \theta^* = \frac{0.044 (\log R_x + 2.3686) T_o \sqrt{r^* R^*} \left( \frac{y + 1}{2} \right)}{(\log R_x + 1.5)^{5/2} T^*} \int_0^1 \frac{1}{M^{1.5 + H_{tr}}} \frac{dM}{(1 + \frac{\gamma - 1}{2} M^2)^{4(y - 1)}} \]  

(60)

or, when \( \gamma = 1.4 \),

\[ \theta^* = \frac{0.0694 (\log R_x + 2.3686) T_o \sqrt{r^* R^*}}{(\log R_x + 1.5)^{5/2} T^*} \int_0^1 \frac{1}{M^{1.5 + H_{tr}}} \frac{dM}{(1 + 0.2 M^2)^4} \]  

(61)

The integration indicated in Eq. (61) can be performed analytically for values of \( H_{tr} \) which are odd multiples of 0.5. For intermediate values, the integration must be performed numerically. The results of such integrations are shown in Fig. 4.

For conical nozzles in which radial flow can be assumed, the Mach number is constant over each spherical segment of area \( 2\pi r^*/(1 + \cos \omega) \). Since the throat area is \( \pi r^*^2 \),

\[ \frac{A}{A^*} = \frac{2r^2}{(1 + \cos \omega) r^*^2} = \frac{1}{M} \left[ \frac{1 + \frac{\gamma - 1}{2} M^2}{\frac{\gamma + 1}{2}} \right]^{\frac{\gamma + 1}{2(y - 1)}} \]  

(62)

or

\[ \frac{r}{r^*} = \sqrt{\frac{1 + \cos \omega}{2 M}} \left[ \frac{1 + \frac{\gamma - 1}{2} M^2}{\frac{\gamma + 1}{2}} \right]^{\frac{\gamma + 1}{2(y - 1)}} \]  

(63)

from which

\[ \frac{dr}{dM} = \frac{r^*}{2} \sqrt{\frac{1 + \cos \omega}{2 M^3}} \left( M^2 - 1 \right) \left( \frac{\gamma + 1}{4(y - 1)} \right) \]  

(64)
Then, since \( \frac{dr}{dx} = \tan \omega \)

\[
dx = \frac{r^*}{2} \sqrt{\frac{1 + \cos \omega}{2M^2}} \frac{(M^2-1)\left(1 + \frac{y-1}{2} M^2\right)^{\frac{5-3y}{4(y-1)}} \cot \omega}{\left(\frac{y+1}{2}\right)^{\frac{y+1}{4(y-1)}}} \ dM
\]  

(65)

Substituting Eqs. (63) and (65) into Eq. (10) yields

\[
\left[ \theta \frac{r^*}{r^*} \left( \frac{T_e}{T_o} \right)^{\frac{y+1}{2(y-1)}} M^{2+H_{tr}} \right]_b = \left[ \theta \frac{r^*}{r^*} \left( \frac{T_e}{T_o} \right)^{\frac{y+1}{2(y-1)}} M^{2+H_{tr}} \right]_a
\]

\[
+ \frac{r^* \left(1 + \cos \omega\right) \csc \omega}{4 \left(\frac{y+1}{2}\right)^{\frac{y+1}{2(y-1)}}} \int_a^b \frac{(M^2-1)M^{H_{tr}} C_f/2}{1 + \frac{y-1}{2} M^2} \ dM
\]  

(66)

As before, if the reference temperature and reference Reynolds number can be assumed to be constant,

\[
\left[ \theta \frac{r^*}{r^*} \left( \frac{T_e}{T_o} \right)^{\frac{y+1}{2(y-1)}} M^{2+H_{tr}} \right]_b = \left[ \theta \frac{r^*}{r^*} \left( \frac{T_e}{T_o} \right)^{\frac{y+1}{2(y-1)}} M^{2+H_{tr}} \right]_a
\]

\[
+ \frac{r^* \left(1 + \cos \omega\right) \csc \omega T_o C_f}{8 \left(\frac{y+1}{2}\right)^{\frac{y+1}{2(y-1)}} T'} \int_a^b \frac{(M^2-1)M^{H_{tr}}}{1 + \frac{y-1}{2} M^2} \ dM
\]  

(67)

and, if \( y = 1.4 \)

\[
\left[ \theta \frac{r^*}{r^*} \left( \frac{T_e}{T_o} \right)^{\frac{y+1}{2(y-1)}} M^{2+H_{tr}} \right]_b = \left[ \theta \frac{r^*}{r^*} \left( \frac{T_e}{T_o} \right)^{\frac{y+1}{2(y-1)}} M^{2+H_{tr}} \right]_a
\]

\[
+ \frac{0.00637 \left(\log R_{x'} - 2.3686\right) T_o r^* \cot \frac{\omega}{2}}{\left(\log R_{x'} - 1.5\right)^2 T'} \int_a^b \frac{(M^2-1)M^{H_{tr}} \ dM}{(1 + 0.2 M^2)^2}
\]  

(68)

The integration indicated in Eq. (68) can be performed analytically when \( H_{tr} \) is an integer and numerically when \( H_{tr} \) is not an integer. The results of such integrations are shown in Fig. 5 where the integration in each case is performed, for convenience, over the interval from 1 to \( M \). Obviously,

\[
\int_a^b f(M) \ dM = \int_a^b f(M) \ dM - \int_1^a f(M) \ dM
\]
For the general case of conical and contoured nozzles, the reference
temperature and Reynolds number are not constant, and for the con-
toured nozzle the radius is not an analytic function of the Mach number.
Equation (53) must therefore be used downstream of the throat while
Eq. (60) or (61) can be used to estimate the value at the throat. In
many cases, the variation of $R_x$ over the length of the nozzle is small
enough that a constant average value of $R_x$ can be used and the computa-
tions involved can thereby be simplified.

Values of boundary-layer displacement thickness calculated by the
method described are compared with experimental values in Figs. 6
and 7 for Mach 7 and 8 conical nozzles and in Fig. 8 for a Mach 8
contoured nozzle. The experimental data were obtained in the 50-inch-
diameter nozzles of the Gas Dynamics Facility. The agreement shown
is considered to be extremely good.

CONCLUDING REMARKS

A method has been developed for calculating the growth of a
turbulent boundary layer at hypersonic Mach numbers. Excellent
agreement with experimental results from axisymmetric nozzles has
been obtained through the application of this method. The basis for the
calculations is Eq. (10) wherein the compressible skin-friction
coefficient is obtained from Eq. (36), and the transformed form factor
is given by Eq. (13) in which the incompressible form factor is related
by Eq. (42) to the incompressible skin-friction coefficient evaluated at
the incompressible Reynolds number given by Eq. (52).
APPENDIX A

STEWARTSON'S TRANSFORMATION

In the Stewartson's transformation, as given in Ref. 9, the distance normal to the surface is transformed by the relation

\[ dY = \frac{\rho}{\rho_0} \frac{a_e}{a_o} dy \]  \hspace{1cm} (A-1)

and the velocity parallel to the surface is transformed by the relation

\[ U = u \frac{a_o}{a_e} \]  \hspace{1cm} (A-2)

External of the boundary layer

\[ U_e = u_e \frac{a_o}{a_e} \]  \hspace{1cm} (A-3)

so that

\[ \frac{U}{U_e} = \frac{u}{u_e} \]  \hspace{1cm} (A-4)

The definition of boundary-layer momentum thickness is

\[ \theta = \int_0^\Delta \frac{\rho u}{\rho_0 u_e} \left( 1 - \frac{u}{u_e} \right) dy \]  \hspace{1cm} (A-5)

where \( \Delta \) is the value of \( y \) where both velocity and temperature reach their free-stream values. Substitution of Eqs. (A-1) and (A-4) into Eq. (A-5) yields

\[ \theta = \frac{\rho_o}{\rho_e} \frac{a_o}{a_e} \int_0^\Delta \frac{U}{U_e} \left( 1 - \frac{U}{U_e} \right) dY \]  \hspace{1cm} (A-6)

The transformed momentum thickness is defined as

\[ \theta_{tr} = \int_0^\Delta \frac{U}{U_e} \left( 1 - \frac{U}{U_e} \right) dY \]  \hspace{1cm} (A-7)

so that

\[ \theta = \frac{\rho_o}{\rho_e} \frac{a_o}{a_e} \theta_{tr} \]  \hspace{1cm} (A-8)
or

\[ \theta = \theta_{tr} \left( 1 + \frac{\gamma - 1}{2} M^2 \right)^{\frac{\gamma + 1}{2(\gamma - 1)}} = \theta_{tr} \left( \frac{T_p}{T_e} \right)^{\frac{\gamma + 1}{2(\gamma - 1)}} \]  

(A-9)

It may be noted that Eq. (A-7) has the form for incompressible flow, although the shape of the velocity profile is distorted by the transformation (see Ref. 24).

In a similar manner, the boundary-layer displacement thickness is defined by the equation

\[ \delta^* = \int_0^\Lambda \left( 1 - \frac{\rho}{\rho_e} \frac{u}{u_e} \right) \, dy \]  

(A-10)

Since the pressure is assumed to be constant through the boundary layer, Eq. (A-10) may be written as

\[ \delta^* = \int_0^\Lambda \frac{\rho}{\rho_e} \left( \frac{T}{T_e} - \frac{u}{u_e} \right) \, dy \]  

(A-11)

The static temperature distribution through the boundary layer may be expressed by

\[ \frac{T - T_e}{T_e} = -\frac{\gamma - 1}{2} M^2 - \frac{\gamma - 1}{2} M^2 \left( \frac{u}{u_e} \right)^2 \]  

(A-12)

where \( T_s \) is the local stagnation temperature corresponding to the local static temperature \( T \). Substituting Eqs. (A-1), (A-4), and (A-12) into Eq. (A-11) yields

\[ \delta^* = \frac{\rho_a \alpha_a}{\rho_e \alpha_e} \int_0^\Lambda \left[ \left( 1 + \frac{\gamma - 1}{2} M^2 \right) \left( \frac{T_s}{T_o} - \frac{U}{U_e} \right) + \frac{\gamma - 1}{2} M^2 \frac{U}{U_e} \left( 1 - \frac{U}{U_e} \right) \right] \, dY \]  

(A-13)

or

\[ \delta^* = \frac{\rho_a \alpha_a}{\rho_e \alpha_e} \left[ \left( 1 + \frac{\gamma - 1}{2} M^2 \right) \delta_{tr}^* + \frac{\gamma - 1}{2} M^2 \theta_{tr} \right] \]  

(A-14)

where, by definition

\[ \delta_{tr}^* = \int_0^\Lambda \left( \frac{T_s}{T_o} - \frac{U}{U_e} \right) \, dY \]  

(A-15)
When \( T_s \) is constant and equal to \( T_o \), Eq. (A-15) has the form for incompressible flow.

Division of Eq. (A-14) by Eq. (A-8) yields

\[
\frac{\delta^*}{\theta} = \left(1 + \frac{\gamma - 1}{2} M^p\right) \frac{\delta_{tr}^*}{\theta_{tr}} + \frac{\gamma - 1}{2} M^p
\]  
(A-16)

or

\[
\Pi = \Pi_{tr} \left(1 + \frac{\gamma - 1}{2} M^p\right) + \frac{\gamma - 1}{2} M^p
\]  
(A-17)

Equations (A-9) and (A-17) were used to transform Eq. (3). Equation (A-15) may be written as

\[
\delta_{tr}^* = \int_0^\Lambda \left[\left(\frac{T_s}{T_o} - 1\right) + \left(1 - \frac{U}{U_e}\right)^2\right] dY
\]  
(A-18)

so that

\[
\Pi_{tr} = \frac{1}{\theta_{tr}} \int_0^\Lambda \left(\frac{T_s}{T_o} - 1\right) dY + \Pi_i
\]  
(A-19)

where

\[
\Pi_i = \frac{1}{\theta_{tr}} \int_0^\Lambda \left(1 - \frac{U}{U_e}\right) dY
\]  
(A-20)

In order to evaluate Eq. (A-19), use is made of Crocco's quadratic temperature distribution, written as in Ref. 8,

\[
\frac{T}{T_e} = \frac{T_w}{T_e} - \left(\frac{T_w - T_{aw}}{T_e}\right)\left(\frac{u}{u_e}\right) - \left(\frac{T_{aw} - T_e}{T_e}\right)\left(\frac{u}{u_e}\right)^2
\]  
(A-21)

which assumes that the thermal boundary layer has the same thickness as the velocity boundary layer. This would occur only if the Prandtl number is unity. However, Eq. (A-21) partially accounts for Prandtl numbers other than unity through the use of the adiabatic wall temperature instead of the stagnation temperature. Substitution of Eq. (A-21) into Eq. (A-11), along with Eqs. (A-1) and (A-4) yields

\[
\delta^* = \frac{\rho_o \sigma_o}{\rho_e \sigma_e} \int_0^\Lambda \left[\frac{T_w}{T_e} \left(1 - \frac{U}{U_e}\right) + \left(\frac{T_{aw} - T_e}{T_e}\right)\left(1 - \frac{U}{U_e}\right)^2\right] dY
\]  
(A-22)
Division of Eq. (A-23) by (A-8) yields

\[
\delta^* = \frac{\rho_o}{\rho_e} \left[ -\frac{T_w}{T_e} \int_{0}^{\Delta} \left( 1 - \frac{U}{U_e} \right) dY + \left( \frac{T_{aw}}{T_e} - 1 \right) \theta_{tr} \right] \quad (A-23)
\]

Equations (A-24) and (A-17) may be combined so that

\[
H = \frac{T_w}{T_e} H_1 + \frac{T_{aw}}{T_e} - 1 \quad (A-24)
\]

Equations (A-24) and (A-17) may be combined so that

\[
H_{tr} = H_1 \frac{T_w}{T_o} + \frac{T_{aw}}{T_o} - 1 \quad (A-25)
\]

The variation of \( H \) according to Eq. (A-24) as a function of Mach number is compared in Fig. 9 with experimental results from Refs. 10 and 25 and in Fig. 10 with the tabulated results from Ref. 26. The correlation is considered to be very good and justifies the derivation described.
APPENDIX B

INCOMPRESSIBLE SKIN-FRICTION COEFFICIENTS

A great many empirical equations have been developed for the variation of the local and mean skin-friction coefficients with Reynolds number for incompressible flow. Probably the most simple to use are the power-law equations

\[
\frac{C_{\text{f}}_i}{2} = \frac{a}{\left( R\theta_i \right)^{1/N}} \tag{B-1}
\]

\[
\frac{C_{\text{f}}_i}{2} = \frac{\beta}{\left( R_{x_i} \right)^{1/(N+1)}} \tag{B-2}
\]

\[
\frac{C_{F_i}}{2} = \frac{R\theta_i}{R_{x_i}} = \frac{N + 1}{N} - \frac{C_{f_i}}{2} \tag{B-3}
\]

where

\[
\beta = \frac{a^{N+1}}{\left( \frac{N+1}{N} \right)^{N+1}} \tag{B-4}
\]

For a limited range of Reynolds numbers, values of \(a\), \(\beta\), and \(N\) can be considered to be constant; but, for a large range of Reynolds numbers, their values must also be functions of the Reynolds number.

Locke (Ref. 27) investigated a number of the empirical equations and found that Schoenherr's equation

\[
\frac{0.242}{\sqrt{C_{F_i}}} = \log \left( C_{F_i} R_{x_i} \right) \tag{B-5}
\]

gave a good correlation with a very large amount of experimental data over the wide range of Reynolds numbers from \(10^5\) to \(10^7\). Other forms of this equation are

\[
\frac{0.242}{\sqrt{C_{F_i}}} = \log \left( 2 R\theta_i \right) \tag{B-6}
\]
and

$$C_f = \frac{(0.242)^2}{\log (2 R\theta_i) \left[ \log (2 R\theta_i) + 0.8686 \right]}$$  \hspace{1cm} (B-7)

Although Schoenherr's equations correlate well with experimental results, they are difficult to use because neither $C_f$ nor $C_F$ can be found directly as a function of $R_{x_i}$. Tables can be constructed for use when the computing is done manually; however, more direct equations are desired for use with automatic computers. Any set of equations must satisfy the relationship

$$C_f = C_F + R_{x_i} \frac{d C_F}{d R_{x_i}}$$  \hspace{1cm} (B-8)

or

$$C_F = \frac{1}{R_{x_i}} \int_{0}^{R_{x_i}} C_f \, dR_{x_i}$$  \hspace{1cm} (B-9)

After an investigation of several types of equations, the equations

$$C_F = \frac{0.088}{(\log R_{x_i} - 1.5)^3}$$  \hspace{1cm} (B-10)

and

$$C_f = \frac{0.088 \left( \log R_{x_i} - 2.3686 \right)}{(\log R_{x_i} - 1.5)^3}$$  \hspace{1cm} (B-11)

were found to correlate with experimental data as well as Schoenherr's equations over the range of Reynolds numbers from $10^5$ to $10^9$. A comparison of values of $C_F$ calculated from Eq. (B-10) with those from Eq. (B-5) is shown in Fig. 11 together with the "ideal" values from Ref. 28 and 29. A similar comparison of values of $C_f$ is shown in Fig. 12 together with experimental values of Dhawan (Ref. 30), Schultz-Grunow (Ref. 31), and Kempf (Ref. 32). These data are recognized as being among the most accurately determined values available. A further comparison of $R\theta_i$ as a function of $R_{x_i}$ is made in Fig. 13 with the experimental values of Wieghardt (Ref. 33). All of these comparisons indicate the validity of Eqs. (B-10) and (B-11).

A critical examination of the curve of Eq. (B-10) shows that it crosses Schoenherr's curve at a Reynolds number of about $10^7$ and again at about $5 \times 10^7$. Moreover, it goes to infinity when $\log R_{x_i} = 1.5$ or $R_{x_i} = 32$. Furthermore, the curve of Eq. (B-11) has zero slope when
log $R_{xi} = 2.3686$ or $R_{xi} = 234$. Both of these conditions are well below the range for turbulent boundary layers and are, therefore, of academic interest only. The values of the constants, 0.088 and 1.5, could have been chosen to agree better with Coles' values but the experimental values do not warrant such a selection.

The incompressible form factor $H_i$ is also a function of Reynolds number and is shown in Ref. 29 to be related to the skin-friction coefficient in the manner,

$$H_i = \frac{1}{1 - 7\sqrt{C_f}/2}$$

where the constant 7 (although different from that of Ref. 29) is chosen for correlation with experimental data. Such correlations are shown in Figs. 14 and 15. Again the correlations are quite satisfactory.

For comparative purposes, values of $C_{Fi}$, $C_{Li}$, $R_{\theta i}$, and $H_i$ are listed in Table 1 for various values of $R_{xi}$ from $10'$ to $10'$. Also listed are the values of $N$ obtained from Eq. (B-3) which show that the use of Eqs. (B-1) and (B-2) must be limited to small ranges of Reynolds number.
