INTRODUCTION

A cavitation-erosion resistant ambient-curing, solvent type neoprene coating, Formulation ML-C570, developed by the Material Laboratory under authorization of references (a) and (b) has been applied to the foils, struts, flaps and rudders of the PC(H)-1, at the J. M. Martinac Company, Tacoma, Washington. The application was started 11 June 1962 and completed in August 1962. This report will describe and discuss the application procedures and their suitability under shipyard conditions, materials employed, and characteristics of the coating as determined in the Material Laboratory.

BACKGROUND

The erosion resistance and other characteristics of the ML-C570 coating material as determined in the Material Laboratory were described at a meeting in Code 634C of the Bureau on 20 November 1961. Attendees at this meeting are listed in enclosure (1). This meeting had been convened to discuss cavitation erosion of a 22 ft diameter manganese nickel bronze propeller of the USNS AMERICAN EXPLORER (T-AO-165), and means of controlling this damage.

It had been indicated in references (c) and (d) that under non-supercavitating conditions of operation, the foils and struts of hydrofoil craft would be required to have a high degree of corrosion and cavitation erosion resistance. In view of the low cavitation erosion resistance of epoxy coatings as reported in reference (e) and on the basis of the high erosion resistance of the ML-C570 coating, reported as described above, a change order was issued under reference (f), substituting the application of the ML-C570 neoprene coating for the previously specified HYCON-75 epoxy coating, on the foils, struts, rudders and flaps of the PC(H)-1.

DESCRIPTION

The application of the ML-C570 coating and related primers, adhesives and smoothers, to the structures of the PC(H)-1, is described in detail in enclosure (2), including:

a. Structures coated (also illustrated in enclosures (3), (4), (5)).
b. Surface preparation.

c. Facilities for application of coating.

d. Coating materials.

e. Coating application procedures.

Personnel of the J. M. Martinac Company, The Boeing Company and SUPSHIPS, USN, Seattle, were instructed in the surface preparation of the structural parts, the use of the coating materials and their application to the foil and strut sections of the PC(H)-l by Material Laboratory engineer, J. Z. Lichtman, during his assignment to the Martinac Company from 11 to 22 June 1962. The spray application of the catalyzed ML-C570 coating was tested at the Martinac Company, using a Graco airless spray gun, Model 205-162, Series 6A1, with a 163-821 tip. A uniform coating was not obtained. Therefore the brush-application procedure, described in enclosure (2), was used in the present application.

5. TESTS FOR COATING PROPERTIES

Test specimens prepared simultaneously and in an identical manner to the preparation and coating of the forward strut, rudders and flaps, were forwarded to the Material Laboratory for test. These tests included:

a. Cavitation erosion resistance.

b. Mechanical properties of supported and unsupported films in:

   (1) Initial condition, and

   (2) After fresh water immersion.

Test specimens prepared in the Material Laboratory were also subjected to the above tests, including, in addition, evaluation of mechanical properties after exposure to 4% simulated sea water for periods up to 28 days.

c. Cavitation erosion exposure: The 12 in. dia. x 1/8 in. thick cavitation test disks were run in the rotating disk apparatus at 3200 rpm and 15 psig, as described in references (j) and (k), using fresh water or sea water, as shown in enclosure (6). Erosion measurements of the metallic specimens were made after the exposure periods, using a microsyringe, Hamilton Company No. 701-N (10 µL capacity, 0.2 µL graduations) or No. 705-N (50 µL capacity, 1 µL graduations). The liquid used in the erosion volume measurements was a silicone oil of 50 cs viscosity.
d. Mechanical properties determined included:

(1) Tensile strength: reference (i), Method 4111.
(2) Ultimate elongation: reference (i), Method 4121.
(3) Tear strength: reference (j), Method 4221.
(4) Tensile hysteresis: reference (j), paragraph 5.c.
(5) Volume swell: reference (1), Method 6221.
(6) Adhesive Strength: reference (1), Method 8031.
(7) Tensile modulus: reference (i), Method 4131.

Results of cavitation erosion exposure on the ML-C570 coating material applied under field and laboratory conditions, and of ferrous structural materials exposed under the same conditions are shown in enclosure (6). Results of evaluation of the mechanical properties of the ML-C570 coating material are summarized in enclosure (7).

6. CONCLUSIONS

The following conclusions are indicated by the results of the described application and tests of the coating materials:

a. Brush application of the solvent-type ambient curing neoprene coating ML-C570 to large, irregularly-shaped structures as represented by the foils, struts, rudders and flaps of the FC(4)-1 is feasible and practical. Application procedures as described in enclosure (2) were used by shipyard personnel without difficulty.

b. The values of properties of the coating material as applied in the field are comparable and, in some instances, superior to those obtained on laboratory-applied samples, as shown in enclosure (7). The initial tear and adhesion properties of the Tacoma samples were somewhat higher than the Laboratory-prepared samples, while the tensile strength and ultimate elongation properties of the Laboratory-prepared samples were higher than those of the Tacoma samples.

c. Although spray application of the ML-C570 coating was attempted as described in paragraph 4, this formulation is applicable by brush only, in accordance with procedures described in enclosure (2), section e.
d. Long time immersion of the coating in fresh and sea water resulted generally in slight decreases in tensile strength, ultimate elongation, tear strength and adhesive strength of the coating. Evidence of blistering after long-time immersion of the Tacoma samples indicates the need for more thorough cleaning and priming of the substrate to prevent localized adhesion separation because of internal stresses. As indicated by Evans, reference (g), the tendency to blister may be stronger in distilled water than in sea water. This factor, as well as the more uniform cleaning of the adhesion test specimens in the Laboratory application, may account for the lack of blistering of the specimens exposed in sea water despite their lower adhesive strength.

7. REPAIR PROCEDURES

Areas of the ML-C570 coating which may be damaged after application, and during or after installation of coated structures in the boat, may be repaired as described in enclosure (8) and reference (h).

8. RECOMMENDATIONS AND FUTURE WORK

Investigation of the ML-C570 coating material to determine its anti-fouling properties is presently underway. Also, other elastomeric coating systems designed for superior erosion and fouling resistance are being developed. Therefore, recommendations for further service applications of the ML-C570 coating will be held in abeyance at the present time, pending results of present service applications and the above development work.

DESCRIPTION OF APPLICATION OF COATING MATERIALS
TO STRUCTURAL SECTIONS OF PC(H)-1

a. Structures of PC(H)-1 Coated with Neoprene Formulation ML-C570

The structures of the PC(H)-1 coated during the period 11 June to 22
June 1962 included the following:

(1) Forward Strut, Figures 1A, B, D, 2H, J, K
(2) Forward Flaps, Figures 1B, 1D, 2L, 3P
(3) Forward rudders (upper and lower) Figures 1A, B, D, 2I, L

These sections had previously been subjected to load deflection tests, the
fixtures for which are shown attached to the foil in Figures 1A, 5

Other Sections coated from 22 June to August 1962 included:

(1) Forward foil, Figures 1A, B, D, E, 3P
(2) Aft struts, Figures 1C, 1F
(3) Aft flaps, Figure 3M
(4) Aft foils, Figures 3M, N, O

b. Surface Preparation

All metallic surfaces to be coated were disk ground to remove the pre-
viously applied 117 pretreatment primer and 84 anti-corrosive coatings. The
disks used in grinding were Type BFH, MOS 6000 RPM, 9 x 1/8 x 7/8, A 2A-5-BFH,
supplied by the Pacific Grinding Wheel Company, Everett, Washington. The
roughness of the metal surfaces after grinding was approximately 150-180 μ in.

c. Facilities used in Application of Cavitation-Erosion Resistant Coating
to PC(H)-1

After surface grinding to remove all the previously applied 117 pre-
treatment and 84 anti-corrosive coatings, the parts were moved into a shed
shown in Figure 28. This shed, approximately 40 ft long by 15 ft wide by
10 ft high was equipped with a removable roof to permit placing into the
shed the larger foil and strut sections, which would not clear the doors
and would require handling by crane. The shed had a fan blowing inward through a filter to provide positive pressure in the building and prevent dust sifting inward. Steam coils were located along the long walls near the floor to provide heat when the room temperature dropped below 60F. To supplement the natural light entering through the plastic roof panels, drop lights were provided for illumination of the under sides of structures during coating. A temperature range of 60 to 88F and relative humidity range of 36 to 72% was obtained in the shed during the period of 11 June to 22 June 1962.

d. Coating Materials

The coating materials included the following:

(1) Metal degreasing agent, Trichloroethylene (TCE)

(2) Pretreatment primer, Formula 117, Specification MIL-C-15328A

(4) Neoprene Coating, Material Laboratory Formulation ML-C570. Formulation developed by Naval Material Laboratory, manufactured by Rubber and Asbestos Corporation, 225 Belleville Avenue, Bloomfield, New Jersey because of quantity required (176 gals).

Formulation:

<table>
<thead>
<tr>
<th>Base: Neoprene AD 20</th>
<th>100 part by wt</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hi Sil 233</td>
<td>20 part by wt</td>
</tr>
<tr>
<td>Bentone 27</td>
<td>1 part by wt</td>
</tr>
</tbody>
</table>

Processing: Band the Neoprene AD 20. Mix Bentone 27 into 1/3 of Hi Sil 233. Incorporate this mix into neoprene, followed by addition of remaining Hi Sil 233. Mill to obtain smooth compound. Refine and sheet off. Dissolve in toluene/amyl acetate (1:1 by wt) to a 20% solution by weight. Viscosity of base solution shall be in range of 1000 to 5000 cps as determined with Brookfield Model RV viscometer at 20 rpm, with a No. 4 spindle at 77F in a 1 pt can.

Catalyst: Catechol solution in toluene 1% by weight. Packaged in units of 0.37 gal catalyst (in 1 gal can) per 4 gals of base (in 5 gal can).
(5) Epoxy smoother primer. Coast Pro-Seal Formula 820 (2 part). Coast Pro-Seal and Mfg Co., 2235 Beverly Road, Los Angeles 57, California.

(6) Epoxy smoother. Coast Pro-Seal Formula 813 (2 part).

(8) Toluene (technical grade). For use in tackifying neoprene coating and in washing brushes.

(9) Methyl ethyl ketone (MEK) (technical grade). May be used in thinning Bostik 1007. Approximately 5% of MEK may be used to increase coverage of Bostik 1007 and to obtain more uniform adhesive coating. The cost and coverage estimates of the neoprene coating material and adhesives furnished by the Material Laboratory are given in Table 2.

Coating Application Procedures

1. Application of neoprene 570 to base HX 80 steel and Type 316 stainless steel weldment inlays.

   (a) Degrease metal thoroughly with TCE, using clean cloths or stiff bristle brush, and allow a 20 minute dry time.

   (b) Apply 1 brush coat Formula 117 primer, and allow a 40 minute dry time.

   (c) Apply 1 brush coat of Bostik 1007 adhesive and allow a 60 minute dry time.

   (d) Apply neoprene coating ML-6570 (2 part) by brush.
Material Laboratory

1 gal can of catalyst (0.37 gal) to a 5 gal can (containing 1 gal) of base. (100 cc catalyst per kg base), 1 hr degassing time after mixing. Pot life 16 hrs.

Dry time per coat 15-60 min to obtain tack-free condition prior to application of next coat. After drying for several hours (e.g. overnight) last coat is tack free. If necessary, apply with solvent before applying additional coats of ML-C570. Prior to tackifying, thickness of applied coating is to be determined with thickness gauges. Final thickness to be 30 to 40 mils (determined by approximately 25 coats). The coating is then allowed to cure at least 7 days at higher than 60°F.

(2) Application of Coast Proseal epoxy smoother formula 813 to depressions in foils (See Figure 2L) recesses in struts, foils and rudders.

(a) Degrease with TCE, using clean cloths or stiff brush and allow a 20 min dry time.
(b) Apply 1 brush coat Formula 117, and allow a 40 min dry time.
(c) Brush apply 1 coat Coast Proseal epoxy Formula 820 (Equal parts by volume of parts A and B), and allow a 12 hour cure time.
(d) Apply Coast Proseal Formula 813 (Equal parts by volume of parts A and B). Smooth out to faired surface. Cure 12 hours.
(e) Finish grind to faired surface.

(3) Application of Neoprene 570 to epoxy smoother.

(a) Wash epoxy smoother with toluene, using clean cloth.
(b) Make up epoxy-neoprene adhesive described in enclosure (2) d 7. Raybond 86009 adhesive to consist of 3 parts base to 2 parts activator by weight and to be added to catalyzed ML-C570 in 1:1 ratio by weight. Typical formula to consist of:

Raybond 86009 base (3 pts by wt): 15 gms
activator (20 pts by wt): 10 gms
Neoprene 570 base + catalyst 25 gms

(c) Brush 1 coat of epoxy-neoprene adhesive onto cleaned smoother.
(d) Allow to dry approximately 2 hours until tacky.
(e) Apply catalyzed neoprene ML-0570 as in (1)(d) above.

(4) Application of neoprene 570 to pressure-sensitive aluminum foil covering (adhesive type PS-18) used in waterproofing of external strain gages on aft struts and hydrofoil.

(a) Degrease HY80 with TCE, using clean cloths or brush.

(b) Degrease aluminum foil surface with TCE.

(c) Cut aluminum foil with scissors to desired form. Remove masking tape from adhesive. Apply foil to metal and roll down with smooth-faced steel roller (Hoggson and Pettis Co. 1-1/2 in. x 1-1/2 in. or equal).

(d) Apply 1 brown coat II7 primer to aluminum and adjacent HY80 steel, and allow a 40 m\(^2\) dry time.

(e) Apply Bostik 1007 and Neoprene ML-0570 as in (1)(c) and (d) above.

(5) Forward Strut

(a) Strut was mounted in jig as shown in Figure 2 H, after surface preparation, enclosure (2) b.

(b) All joint and bearing areas were masked.

(c) Coating applied as described in (1) through (3) above to within 2 inches of lower flange and to bolt cavity of upper flange, Figure 1 D, 2 H and K.

(d) Coating in upper rudder recess areas adjacent to rudder surface, Figure 2K, applied to thickness of 15 mils for clearance in rudder operation.

(6) Rudders and Flaps

(a) Lower rudder positioned as shown in Figure 2I, upper rudder hung as shown in Figure 2L. Micarta bearing shims bonded to HY80 with Coast Proseal Formula 513 epoxy.

(b) Flaps positioned on wood horses as shown in Figure 2L. All joints, bearing areas and holes for Locktite installation masked. Depressions in flap surfaces smoothed as described in (2) above. Neoprene ML-0570 applied to thickness of 15 mils at leading edge areas and hinge areas, Figure 1E and 2L. Otherwise, thickness of coating was 30 to 40 mils as indicated in (1) above.

B. Forward Foil and Strut Assemblies.

C. Aft Struts.

D. Forward Foil and Strut Showing Attachment Bolts.

E. Forward Foil. Flap Removed.

COATING REPAIR PROCEDURES

Areas of the ML-C570 neoprene coating which have been damaged during or after assembly of the coated sections or operation of the boat shall be repaired in the following manner. The original coating shall be faired at the damaged margins using a sharp knife or 80 grit sand paper. The faired coating surface shall be tackified using a light brush coat of toluene. The catalyzed ML-C570 shall then be applied, fairing in the patch as it is applied. If the original coating has been damaged to the base metal and adhesion failure has occurred, the coating shall be cut away to the extent of adhesion separation and faired at the residual margin. The metal shall be cleaned using abrasive cloth (50 mesh) to white metal, washed with TCE and reprimed with 117 primer and Bostik 1007 adhesive prior to recoating with ML-C570. The new coating material shall be faired carefully into the original coating margin to prevent a non-smooth surface margin. Should this occur, the roughness shall be smoothed with 80 grit sand paper and brushed lightly with toluene.
