SIMULATION ERROR ANALYSIS
SYSTEM

PROGRAMMING DOCUMENT

Prepared for: 496-L System Program Office
Electronic Systems Division
Air Force Systems Command
United States Air Force
Lawrence G. Hanscom Field
Bedford, Massachusetts

Under Contract: AF 19(604)-7375

30 November 1962
This document presents the theory, program philosophy, and operating instructions for the Simulation Error Analysis System (COSINE 51). As a joint effort undertaken by the RCAF Directorate of Systems Evaluation and the USAF 496L Systems Project Office, the computer system, developed at Aeronutronic, provides an automatic means with which the observations of a specified orbit obtained from a sensor network may be simulated and analysed, yielding the uncertainty in the orbit elements due to the observational inaccuracies. The system also provides the capability of predicting future position and velocity errors caused by the uncertainty in the orbit elements.

The presentation of the document is made in loose leaf binder form with the understanding that the system will not remain static. Rather, it will be in a constant state of modification, adhering to requirements for specialized simulations and improved error analysis techniques. With this design concept therefore, the user may anticipate a series of revisions for future incorporation in the program document.

SECTION 1

INTRODUCTION

A cooperative program of work has been undertaken by the RCAF Directorate of Systems Evaluation (DSE) and the USAF 496L Systems Project Office to provide a background of knowledge which can be applied to a broad range of problems concerning satellite detection, tracking, orbit determination, and prediction of future satellite positions. Aeronutronic has assumed a major portion of the program development through the 496L SPO, with the specific responsibility of computer program design, preparation, and development.

At the time that this joint program was initiated (March 1962), DSE was engaged in an overall study of the system requirements for orbital rendezvous between two space vehicles and 496L SPO was engaged in the development of computer programs for tracking and cataloguing existing and future satellites. One phase of the DSE study, known by the code-name COSINE (Co-orbital Satellite Inspection Evaluation), was of common interest to both the RCAF and the USAF and as such was undertaken as a joint study. This study concerns itself primarily with the problems of initial detection, tracking, orbit determination, and prediction of future satellite position.

The experience of both agencies in their respective fields led to the design and production of a computational system to be used in this study. This document contains a complete description of the system in its present form. As a continuing effort, the system and the documentation will be revised and augmented in the coming months. This philosophy accounts for the notebook presentation of the program manual.

The title Simulation Error Analysis System has been assigned to the computer programs written by Aeronutronic for the 496L SPO. Operationally, this system will be used in the COSINE 5 phase of the DSE study. It greatly intensifies an earlier program for this phase known as COSINE 5A, and has subsequently been assigned the code name of COSINE 5B. The two designations, Simulation Error Analysis System and COSINE 5B, are synonymous and differ only because of the historical background in the system development.
The basic philosophy and gross features of this programming system are presented in the remainder of this section. Subsequent sections provide the user with the program operating instructions, major program unit descriptions, executive program description, subroutine specifications, data block and card formats, and system test cases.

The Simulation Error Analysis System has been developed for the Philco 2000 computer, making extensive use of the Philco 2000 Operating System (SYS).

1.1 PROGRAMMING SYSTEM

This document describes the programming system fulfilling the requirements of the Simulation Error Analysis System. The primary requirement of the Simulation Error Analysis System is to produce a statistical analysis of the errors in predicting satellite position and velocity which arise because of observational inaccuracies. The fulfillment of this specification requires the performance of a comprehensive set of functions, many of which are equally as essential as the primary result. A programming system providing versatility in performing these functions is therefore a fundamental tool for the execution of such analysis. Consistent with this consideration, the programming system concept adopted utilizes execute programs linking individual program units in automatic sequences. A total of eight sequences utilizing combinations of seven program units comprise the total system to date. This modular philosophy thus provides the desired system flexibility which will allow the addition of new sequences and modification of existing sequences in the future. The first program sequence fulfills the above primary requirements while seven additional program sequences provide the necessary versatility for performance of the required secondary functions.

The study objectives that may be achieved with this modular design system include:

1. An investigation of the accuracy with which the orbital elements of a satellite can be established for any given network of ground based sensors and given performance characteristics of each sensor in the network.

2. An assessment of the effectiveness of sensor networks and the extent to which any one sensor in the network can affect orbital elements of a satellite established by the network as a whole.
(3) A study of the effect of smoothing time between successive observations of a sensor on the accuracy of orbit determination.

(4) An evaluation of the relative merits of different types of sensors in which measurements are used to establish the orbit of a satellite.

(5) The determination of the requirements for performance characteristics (measurement accuracies, coverage limits, etc.) of a sensor or a network of sensors for different levels of accuracy in orbit determination. It is important to determine the measurement accuracy beyond which further improvement does not significantly affect the accuracy of orbit determination.

(6) The establishment of corresponding levels of measurement accuracy among different types of sensors to ensure given levels of accuracy of orbit determination.

(7) The determination of the extent to which the number of observations taken by a given sensor affects the quality of the computed orbit and whether there is a point beyond which additional observations do not contribute a significant improvement in the accuracy of a computed orbit.

(8) An investigation of the effect of observing selected segments of a pass over a sensor for use in providing observation schedules for sensors which are required to observe many satellites in orbit at the same time.

(9) An investigation of the existence of any correlations in the errors present in the computed orbital elements.

(10) The frequency distributions of the errors in orbital elements that can be tested for goodness of fit with assumed distribution laws. If consistency with any given law can be established, analytical methods may then be used to obtain the expected errors in orbital elements from a knowledge of the sensor performance characteristics.
An evaluation of the accuracy with which a satellite position can be predicted at some time after the last sensor observation was possible. This is an important requirement in some military and scientific operations (such as orbital rendezvous).

1.2 PROGRAM SEQUENCES

The program sequences consist of various combinations of the following seven program units:

- Acquisition Time Intervals (AQTINT)
- Observation Simulation (OBSIM)
- Monte Carlo (MOCARO)
- Differential Correction (SGPDC)
- Element Error Distribution (DCDIST)
- Error Prediction (ERP)
- Prediction Distribution (ERPDIST)

A detailed description of each program unit is presented in Section 3. A diagram schematically representing all of the program sequences with corresponding program units is presented in Figure 1-1, which also contains a brief summary of each program unit function.

The information processing steps for all sequences are illustrated by Figure 1-1. Figure 1-2 is an expansion showing the outputs of individual program units. Both figures specify the entrances and exits for each of the sequences 1 to 8, indicating the program units utilized by each sequence. These figures illustrate the application for each sequence.

The information processing steps in Sequence 1 are as follows:

1. After Simulation Error Analysis (SEA 1) is loaded in core, the program begins by processing all input case data and loading it in the required core locations. The simulated sensor's observational accuracies represented by fixed values of standard deviations and bias errors are stored in core location SGBLOC. The parameters used to simulate the sensor observing patterns are stored in location IBLOC. Sensor coordinates are loaded in core location SBLOC. The true satellite orbital elements are loaded into location EBLOC.

      2. Statistic of Errors
    - Punched Cards: Statistic of Position Velocity Errors
The data (EBLOC, SBLOC, IBLOC) are processed by the AQTINT Program Unit to provide the times when the satellite is observed by the sensors. These acquisition times are stored in location TBLOC.

Using the data (TBLOC, EBLOC, SBLOC) the OBSIM Program Unit provides a set of simulated observations which are loaded in the Observations block, OBLOC.

The MCARO Program Unit provides K sets of contaminated observations utilizing the sensor accuracy data previously stored in SGBLOC. A Monte Carlo technique is used to generate random sensor errors from the normal distribution of errors with the given fixed standard deviation. These random errors and given bias errors are added to the simulated observations, thus contaminating them in order to represent actual sensor measurements. The contaminated observations are stored in the contaminated observations block, COBLOC.

Residuals in observations (observed minus computed) are formed and a differential correction of the true orbit elements is performed. Computed observations are those obtained by representing the true satellite orbital elements in EBLOC. The Differential Correction Unit, SGPDC, determines a new set of elements which best fit the observations according to a least squares of residuals method. A rejection option is included to reject large observation residuals on an absolute basis and also on a relative basis. The contamination and correction procedure is repeated for the K sets of observations and produces K sets of variant elements which are then stored in the variant elements block, VEBLOC.

Errors in elements, variant minus true, are computed and a statistical analysis is performed by the DCDIST Program Unit. For each element error, the minimum, maximum, mean, and standard deviation is computed and a frequency distribution performed.
(7) The position and velocity vectors of the satellite are predicted by the ERP Program Unit at selected points from each of the variant element sets. Errors are computed relative to the input element set for each of the position and velocity coordinates and the vector magnitudes and are stored in the delta position and velocity block, DPVBLOC.

(8) Two types of statistical analyses are performed by the ERPDIST Program Unit. In one type, the minimum, maximum, mean error, plus the standard deviation are computed and a frequency distribution is performed for each error quantity in DPVBLOC. In the other type, the mean, maximum, and standard deviation of the position and velocity coordinates and the vector magnitudes for selected points in each quadrant of the orbit are treated as error quantities. Their respective minima, maxima, means, and standard deviations are computed for each of the four quadrants of the orbit. This latter feature provides the trend in each quantity over a segment of the orbit; for instance, it supplies the mean of the mean error in position over one quarter of a revolution.

Sequence 2 (SEA 2) enables one to obtain only the acquisition times as the sequence begins with AQINT and terminates at its completion. Sequence 3 (SEA 3) will continue through OBSIM, terminating after computing the observational quantities corresponding to the times generated.

Sequence 4 (SEA 4) performs a function similar to SEA 1, with the exclusion of the error prediction. SEA 4 fulfills the objective of an analysis where only the element error statistics are required and no information concerning the position and velocity prediction is desired.

Sequence 5 (SEA 5) accepts elements, observations, and standard deviations and performs the specified number of Monte Carlo, Differential Correction loops. It then continues into DCDIST which produces a statistic of errors in the classical elements at epoch. Finally, ERP predicts position and velocity errors at specified points which are statistically represented by ERPDIST.

Sequence 6 (SEA 6) is similar to SEA 5 except that it excludes the ERPRED functions. ERPRED incorporates the functions of both ERP and ERPDIST.
SEA 3, combined with SEA 5 or SEA 6, provides for an analysis similar to SEA 1 and SEA 4, respectively; however, with the additional capability of selecting particular observations for the error analysis. SEA 3 performs the satellite simulation, producing the observations in punched card form. The selection of these observational data, fulfilling required experimental conditions, provides input to SEA 5 or SEA 6.

Sequence 7 (SEA 7) is SGPDC run with one set of "real" or contaminated observation input. The orbital elements are corrected at epoch and output. At the completion of the correction, the sequence is terminated. SEA 7 is mainly reserved for correcting actual satellite orbits.

Sequence 8 is an ERPRED run only, with the one set of true elements plus N sets of variant elements input (N \leq 100). SEA 8 provides the capability of repeatedly performing a variety of prediction analyses on a given group of variant element sets produced by any of sequences SEA 1, 4, 5 and 6.

1.3 SIMULATION CAPABILITIES AND LIMITATIONS

The computational model of satellite motion is based on the theory of two-body motion, with the optional provision of including the effects of the secular perturbations on the orbital elements produced by the equatorial bulge of the earth and atmospheric drag.

The control of the simulation of the sensor observing pattern is provided through a specification of desired limits of the initial acquisition elevation angle and the final acquisition elevation angle. Observations from any of the sensors in the simulated network are specified as any combination of angles (right ascension and declination, or azimuth and elevation angle), range, and range rate. The simulation of observations may be constrained to generate only those observations within a range envelope or those observations consistent with a satellite illumination criterion, representative of the sensor capability. The system has the capacity of simulating a sensor network containing up to 100 different stations and the capability of processing up to 2000 observations (500 time points) for a single satellite simulation.

The major restrictions of the programming system require that:

1. Satellite orbital eccentricity, \( e < 1 \).
2. Satellite orbital inclination, \( i \neq 0 \).
3. Satellite orbital period must not be the period of earth rotation.
The modular design of the Simulation Error Analysis System allows the user the freedom of calling for any of the acceptable sequences. The program units and the associated executive routines, subroutines, and storage assignments are compiled in relocatable binary format and are loaded into core at the execution of one of the sequences. For ease of handling and for a saving in machine time, a particular sequence may be compiled onto the user's designated sequence tape. This disencumbers future operation of the particular sequence, eliminating the time consuming tape searching on the SEA tape (Simulation Error Analysis tape) which is necessary in compiling a sequence.

Thus, there are two modes of operation: one of compiling the desired sequence which may be combined with running the sequence, and one of sequence operation using a previously compiled sequence. The latter operation is executed by submitting a standard SYS job setup resulting in the complete sequence being brought into core by the TAC II loader.

2.1 SEQUENCE COMPILATION INSTRUCTIONS

This paragraph describes the use of SYS service routines to generate a sequence as one program to be retained for future SEA runs. All SEA programs are compiled in relocatable binary format (REL) using symbolic references for intraprogram communication. When more than one REL program is loaded into core memory, the TAC II loader* provides the necessary addresses in those instructions referencing symbolic locations.

*See Philco writeup on TAC II and TACII loader.
outside of the original compilation. Therefore, after loading the multiple units comprising a SEA sequence, core will appear as it would if the units had been compiled as one program.

The actual loading of a sequence is accomplished by running a standard SYS job setup with one REL load card for each program comprising the sequence. The last program to be loaded must be EXEC. This REL card has the additional parameters LIST and SUBS. The LIST parameter signals the loader to prepare an edited listing on the output tape (5), giving the octal core address assigned to each symbolic location which was cross referenced between program units. This cross reference aids the programmer in eliminating problems that arise while attempting to run the sequence. The SUBS parameter signals the loader to bring the necessary Philco subroutines into core from the SYS tape (7). These subroutines are also in REL TAC format. Their locations are made available to the sequence programs by symbolic locations in the same manner in which the program units communicate with each other.

After all units have been loaded, core memory will contain the complete sequence in a form suitable for running. The SYS segmentation aids are then used to write the complete sequence on the Sequence Tape in RPL (Running Program Language) format. In general, this will be a separate tape, but the sequence may be written back onto the SEA tape in order to conserve tape usage. The segmenting routine positions the specified tape to the end of current information, writes the new program, and rewrites the "end of data" indicator (a block of Z's).

The reason for loading the sequence once, and writing it on tape in RPL format, is to save computer time when running. It takes approximately 3 minutes to load Sequence I composed of 10 REL units. This time is independent of tape searching time which will be variable depending on the length of the SEA Tape. After the sequence is on the SEA tape in RPL format, it takes less than 10 seconds to load. Therefore, it is to the user's advantage to save the sequence via segmentation aids.

The description below outlines the specific procedure for compiling program sequences.

(1) **Tape Unit Designations**

Set the tape units with the following fixed assignments:

Logical

1. SYS Tape - no write Ring
2. Scratch tape, write Ring

*See Philco R and D Note Number 28*
3. Must have a tape mounted, with or without a write Ring
4. Must have a tape mounted, with or without a write Ring
5. Output tape, write Ring
6. Must have a tape mounted, with or without a write Ring
7. Philco Subroutine tape, no write Ring
8. Input tape, no write Ring

Variable Tape

The SEA tape containing the REL programs will be on one unit, and an optional output tape, other than the SEA tape, can be mounted, (notes c and d below explain these assignments).

(2) Job Deck Setup

One or more of the job decks presented in Figure 2-1 through 2-8 are used as input to SYS by transferring the card data to magnetic tape and using it as the input tape (logical 8).

(3) Restrictions and Variations

The job decks shown are samples and must adhere to the following restrictions:

(a) Program ID's - With new compilations of the program units, the ID's will be changed, i.e., AQINT may be changed to AQINTA. Therefore, it is necessary to see that the current ID is given on the REL card.

(b) Sequence ID's - Because of changes in the program units, it may be necessary to recompile a sequence. If so, the sequence ID must be changed. For example, if Sequence 1 was compiled with the ID on the segment card given as SEQI and a program unit is changed, e.g., AQINT to AQINTA, it is necessary to recompile SEQI calling for AQINTA and also to rename the new compilation, e.g., SEQIA. At run time the
FIGURE 2-1. SEQUENCE 1 COMPILATION
JOB DECK

FIGURE 2-3. SEQUENCE 3 COMPILATION JOB DECK
FIGURE 2-4. SEQUENCE 4 COMPILATION JOB DECK

2-7
FIGURE 2-5. SEQUENCE 5 COMPILATION JOB DECK

2-8
FIGURE 2-6. SEQUENCE 6 COMPILATION JOB DECK

2-9
FIGURE 2-7. SEQUENCE 7 COMPILATION
JOB DECK

2-10
FIGURE 2-8. SEQUENCE 8 COMPILATION JOB DECK
RPL card must also be changed to agree with the new sequence ID. (This ID has a maximum of 8 characters). Care must be taken that no program, either an REL unit or a segmented sequence, be on the same tape twice with the same ID. This will require machine time to remedy and is very costly, both in dollars and time lost.

(c) SEA Tape Mounting - The SEA tape may be mounted on any unit but 1, 2, 5, 7, or 8, and may or may not have a write ring. The tape number "n" on the REL cards in input must correspond to the logical tape number on which the SEA tape is mounted.

(d) Output Tape Mounting - The output tape for the RPL version of the compiled program (Sequence tape) may be on any tape but 1, 2, 4, 5, 7, or 8. The tape number "m" on the SEGMENT card must correspond to the logical tape number on which the output tape is mounted.

It is admissible to write the compiled sequence onto the SEA tape. In this case, the SEA tape must have a write ring, and cannot be on tape unit 4.

(e) Sentinel Block - The "IBIT 0" instruction causes the segmenting program to search the tape for a sentinel block of Z's before writing the program. Therefore, if an "IBIT 0" is used, the tape specified in the SEGMENT instruction must have a block of Z's after all good information. If the "IBIT 0" is not used, the segmenting program will assume that the tape specified is properly positioned and begin writing the RPL program without prepositioning the tape. This is
1. **Simulation Error Analysis System**

An extremely dangerous practice, since an error will destroy the tape data. If the tape on which the sequence(s) will be compiled is a scratch tape it is not the SEA tape and i.e., no programs or sequences have been written on it, it is necessary to precede the first sequence compilation job deck with the following job deck:

```
JOB WRITE SENTINEL
REWIND: m
WRTSENT m, Z Z Z Z Z Z Z
REWIND m
```

If only one sequence is to be compiled on a scratch tape, one has the option of replacing the "IBIT 0" card with a "REWIND m". This will cause the sequence to be written on the beginning of the tape followed by a sentinel block; the tape will be positioned at the beginning of the sentinel block.

2.2 **Sequence Operation**

SEA sequence runs are executed under SYS control. This means that standard SYS tape and input deck setups are used. Tapes required for a sequence run are:

**Logical**

1. SYS Tape
2. Scratch Tape
3. Scratch Tape
4. Sequence Tape
5. Output Tape
6. Scratch Tape
7. Not required
8. Input Tape
9-15. Not required

Sequence output is on Tape 5. Printer or hard copy output is in data select 0. Punched card output is in data select 2 and should be punched in code mode with the "sense control characters" switch set to ignore (Punched Card Controller Switches).

Sequence input is on Tape 8. One job consists of one or more cases on the same SEA sequence, i.e., one job may contain several cases on SEA1 only. Jobs always begin with a JOB card, JOB in Col 17-24, and contain an RPL card, RPL in Col 17-24, calling the sequence desired. Dump cards, DUMP in Col 17-24, are optional and may precede or follow the RPL card. All cards after these are SEA cards and actual input data.

One case in a SEA deck is always preceded by a case card, SEA in Col 17-24, and followed by an ENDDATA card, ENDDATA in Col. 17-24. The last case in a job should be followed by an SYS card, SYS in Col 17-24. In between the case card and the ENDDATA card is the input data consisting of all program control and data cards necessary to run the case. The Job Deck setup required to run sequences 1 to 8 is included in Figures 2-9 through 2-16. Any one case will be subject to the following restrictions:

1. One element set consisting of two element cards is the maximum allowed. This can be type A, B, C, or D. Type C and D elements must be preceded by the associated sensor card.

2. For element input type A or B, 100 sensor cards are allowed. For element types C and D, one sensor card is allowed, the sensor associated with the elements.

3. One hundred simulation parameter cards are allowed. There must be a sensor and a standard deviation card for each different sensor specified on the simulation parameter cards.

4. One hundred standard deviation cards are allowed.

(5) Observations can be standard SPADATS format, 0-9 or \( \wedge \) in Col 80, or SEA format, 0 in Col 80. If the elements are type A or B, either type may be used. If SPADATS format is used, the elements must precede the observations. If elements are types C or D, only SEA format observations are allowed. In any case, 500 observations is the maximum allowed.

(6) A maximum of 500 variant element sets is allowed. These must be type A or B, and must be preceded by the element, nominal elements, input.

(7) One control card of each specified type should be included.
The seven major program units comprising the Simulation Error Analysis System are:

- Acquisition Time Intervals: AQTINT
- Observation Simulation: OBSIM
- Monte Carlo: MOCARO
- Differential Correction: SGFDC
- Element Distribution: DCDIST
- Error Prediction: ERPRED
- Prediction Distribution: ERPDIST

This section presents a detailed description of each program unit in terms of general function, input-output data requirements, computational and logic processes. Also, each program unit is summarized according to system data blocks, associated input cards, and common subroutines used. Reference should be made to Sections 5, 6, and 7 for detailed formats of the respective blocks, cards, and common subroutines.

In addition to the program formulation subsections, a schematic representation of each program unit is also exhibited. These flow diagrams serve to augment the description of the computation and logic processes.
for each program unit. The following definitions of the symbol logic will aid in following these flow diagrams:

- **DESCRIPTION**
  - Operation symbol with operation described within the box.

- **NAME**
  - Outside entrance or exit with symbolic location "NAME".

- **n**
  - Connector, flow chart reference = n.

- **CONDITION**
  - Test or branch - if condition exists, exit to the "yes" path; if condition does not exist, exit to the "no" path. (May be comparison with = vs ≠, < vs ≥, etc).

- **NAME**
  - Common subroutine, "NAME" writeup appearing in Section 5.

- **NAME**
  - Program subroutine, either on flow chart or in program writeup.

- **SWA**
  - Internal program Switch "A" or other designation ("B", "C", etc.) path will vary depending on preset value assigned to the switch.

- **NAME**
  - Written adjacent to any of the symbols above, this is the symbolic location in the coding associated with that function.

The individual program units are preceded in this section by a description of the initializing process. This is not a program unit per se, but is required prior to entering any of the system sequences. The control of this initializing process lies within the executive function of the sequences. Initialization is executed immediately after SYS transfers control to the sequences.
3.1 INITIALIZATION

The computations required before entering any of the program sequences include the conversion of the four input element types (A, B, C, D) to a common type, computation of Greenwich sidereal time at epoch, retrieval of year constants for the sun, and transformation of sensor coordinates to a rectangular form. The system actually contains these computations in the executive subroutines ELMRED and SENCARD and not in a separate initialization unit. The outputs generated by these routines are germane to the program units and therefore are presented in this initialization section.

3.1.1 INPUT-OUTPUT DATA

The input data required by the initializing subroutines include:

(1) **Element cards (four types accepted)**

Type A \((a, e, i, \Omega, \omega, M_0)\)
Type B \((x, y, z, \hat{x}, \hat{y}, \hat{z})\)
Type C \((H_q, e, i, \hat{h}_c, \nu_c, \rho_o)\)
Type D \((a, e, i, \Omega, \omega, \hat{h}_o)\)

(2) **Sensor cards**

The output data produced by the ELMRED subroutine consist of:

(1) **EBLOC** - system data block containing input elements in **M N** form, time of epoch, Greenwich sidereal time at epoch, and satellite identification.

(2) Mean longitude of the sun at the beginning of the epoch year (types A and B only).

(3) Corrective constant used in computing the true longitude of the sun (types A and B only).

The output from the SENCARD subroutine produces **SBLOC**, a system data block containing sensor coordinates in rectangular form.

3-3
3.1.2 FORMULATION

Element types A and B require the computation of the Greenwich sidereal time at epoch, $\theta_o$, by means of

$$\theta_t = \theta_o + 0.9856472 \text{ (integer)} + 360.9856472 \text{ (FRAC)}, \quad (3.1.1)$$

where integer is the day number since the beginning of the year and FRAC is the fractional part of the day. $\theta_o$ is the Greenwich sidereal time at the beginning of the year, obtained from a table look-up procedure, STLC subroutine. This subroutine also provides $L_o$, the mean longitude of the sun at the beginning of the year, and $C_3$, a corrective constant for the same year.

Element type C is arbitrary with respect to epoch, and therefore the conversion of this type is made with the simplifying assumption that $t_o = 0$ and $\theta_o = 0$. Types C and D depend on station location and require the coordinates of the station to be available before conversion.

The transformation of the geodetic station coordinates to rectangular coordinates is accomplished by the relationships,

$$x_c = (C + H) \cos \phi$$

$$y_c = (S + H) \sin \phi$$

where

$y_c =$ sensor position above equatorial plane.

$x_c =$ projection on the equatorial plane of the distance from geocenter to sensor.

The quantities C and S are conversion factors based on the International Ellipsoid with flattening, $f = 1/298.3$, and equatorial radius $a_e = 1$ (6378.15 km),

$$C = \frac{1}{\sqrt{1 - (2f - f^2) \sin^2 \phi}}, \quad (3.1.3)$$

$$S = (1 - f)^2 C. \quad (3.1.4)$$

3-4
and

\[ H = \text{altitude above the reference ellipsoid (approximately sea level).} \]

\[ \phi = \text{geodetic latitude.} \]

The output data block, SBLOC, contains the quantities, east longitude, \( \lambda', -y', -y_c, \phi, \) and \( H. \)

The element conversion subroutines compute the \( MN \) elements

\[ (a_{xN}, a_{yN}, h_x, h_y, h_z, L_0) \]

from any of the four input types, A, B, C or D.

The conversion for classical elements (ETYP) is straightforward. First, the semilatus, \( p, \) is found from the semimajor axis, \( a, \) and the eccentricity, \( e, \) by

\[ p = a(1 - e^2). \quad (3.1.5) \]

The components of the angular momentum vector, \( h, \) follow, using the right ascension of the ascending node, \( \Omega, \) and the inclination, \( i, \)

\[ h_x = \sqrt{p} \sin \Omega \sin i, \quad (3.1.6) \]
\[ h_y = -\sqrt{p} \cos \Omega \sin i, \quad (3.1.7) \]
\[ h_z = \sqrt{p} \cos i. \quad (3.1.8) \]

The nodal components of the \( a \) vector, which depend on \( e \) and the argument of perigee, \( \omega, \) are computed from

\[ a_{xN} = e \cos \omega, \quad (3.1.9) \]
\[ a_{yN} = e \sin \omega. \quad (3.1.10) \]
Finally, the mean longitude at epoch is computed using \( \omega, \Omega, \) and the mean longitude at epoch, \( M_0, \) from

\[
L_0 = M_0 \pm \Omega + \omega, \quad + \text{ for } h_z \geq 0
\]

\[
L_0 = M_0 \pm \Omega - \omega, \quad - \text{ for } h_z < 0.
\]  (3.1.11)

The conversion for the position and velocity elements (ETYPB) requires a more complex set of formulae, which are necessary to avoid the singularities associated with low eccentricity. The components of angular momentum are obtained directly from the position vector \( \mathbf{r} \) and the velocity vector \( \dot{\mathbf{r}} \) in the vector product

\[
\mathbf{h} = \frac{\mathbf{r} \times \dot{\mathbf{r}}}{\sqrt{\mu}}
\]  (3.1.12)

where the vector product is computed using the input components \( \mathbf{r}(x, y, z) \) and \( \dot{\mathbf{r}}(\dot{x}, \dot{y}, \dot{z}) \). The computation of \( p \) follows.

\[
p = \mathbf{h} \cdot \dot{\mathbf{h}}.
\]  (3.1.13)

The orthogonal set of unit vectors is then computed

\[
\mathbf{U} = \frac{\mathbf{r}}{r},
\]  (3.1.14)

\[
\mathbf{W} = \frac{\mathbf{h}}{\sqrt{p}}
\]  (3.1.15)

\[
\mathbf{V} = \mathbf{W} \times \mathbf{U},
\]  (3.1.16)

where \( \mathbf{U} \) is the unit vector along \( \mathbf{r} \), \( \mathbf{W} \) is the unit vector normal to the orbit plane in the direction of the angular momentum vector, and \( \mathbf{V} \) completes the right-handed set. The eccentricity is obtained from

\[
e^2 = (e \cos v)^2 + (e \sin v)^2,
\]  (3.1.17)

where

\[
e \sin v = \sqrt{p/\mu} \dot{r}
\]  (3.1.18)

and

\[
e \cos v = p/r - 1.
\]  (3.1.19)
Equations (3.1.12) and (3.1.18) utilize the mass function, \( \mu \), which is taken as unity in satellite applications. The radial component of the velocity vector, \( \dot{r} \), in Equation (3.1.18) is computed from

\[
\dot{r} = \frac{\mathbf{r} \cdot \dot{\mathbf{r}}}{r}
\]

(3.1.20)

The semimajor axis, \( a \), and subsequently the mean motion, \( n \), are then available through Equation (3.1.5) and

\[
n = k \sqrt{\mu} a^{-3/2}
\]

(3.1.21)

where \( k \) is the geocentric gravitational constant. True longitude at epoch, \( t_0 \), is computed from

\[
t_0 = \tan^{-1} \left[ \frac{y_v - v_x}{y_x + v_y} \right]
\]

(3.1.22)

The nodal components of \( \mathbf{a} \) follow, using

\[
\mathbf{a} = \mathbf{a} \mathbf{e} \cos v - \mathbf{V} \mathbf{e} \sin v
\]

(3.1.23)

which leads to

\[
a_{x_0} = (-a_{W_2} \mathbf{y} + a_{W_3} \mathbf{z})(1 - W_2^2)^{-1/2}
\]

(3.1.24)

\[
a_{y_0} = (-a_{W_2} \mathbf{z} - a_{W_3} \mathbf{x})(1 - W_2^2)^{-1/2} + a_z (1 - W_2^2)^{1/2}
\]

The difference between the true anomaly, \( v \), and the eccentric anomaly, \( E \), is computed from

\[
v - E = \tan^{-1} \left[ \frac{\sin(v - E)}{\cos(v - E)} \right],
\]

(3.1.25)

where

\[
\sin(v - E) = \frac{\sqrt{[e \cos v(e \sin v) + e \sin v]}}{1 + (1 - e)^{1/2}}
\]

(3.1.26)
and
\[
\cos (v - E) = \frac{\pi}{p} \left[ 1 - \frac{(e \sin v)^2}{1 + (1 - e^{1/2}) + e \cos v} \right].
\] (3.1.27)

Combining
\[
e \sin E = \frac{\pi}{p} \sqrt{1 - e^2} e \sin v
\] (3.1.28)

with the results of Equations (3.1.22) and (3.1.25), the mean longitude at epoch is obtained from
\[
L_0 = L_0 - (v - E) - e \sin E.
\] (3.1.29)

The ETYPC conversion routine treats the elements defined by a partial set of elements and a description of the pass over the sensor. This partial set of elements includes the altitude of perigee above the reference ellipsoid, \(H\), the elevation angle of the satellite as it crosses the meridian of the sensor, \(h_c\), the true anomaly of the satellite as it crosses the meridian of the sensor, \(v_c\), \(e\), and \(i\). The elevation angle at culmination is specified either north or south of the sensor's zenith. The pass over the station is specified either north-to-south or south-to-north. Even though these north/south descriptions become incongruous when the satellite is at the apex or zenith positions, no ambiguity exists in the mathematics.

The magnitude of the radius vector from the geocenter to the satellite at culmination is obtained by
\[
r_c = \frac{q(1 + e)}{1 + e \cos v_c}
\] (3.1.30)

where the perigee distance
\[
q = 1 + Hq
\] (3.1.31)

The geocentric latitude of the subsatellite point \(\phi_s\) (Figure 3-1) is computed from
\[
\phi_s = \phi \pm \psi_c', \quad + \text{north of zenith}
\]
\[
\phi_s = \phi - \psi_c', \quad - \text{south of zenith}
\] (3.1.32)

where \(\psi_c\) is the complement of the sum of the angles \((h_c + \beta_c)\)(see Figure 3-2) and
FIGURE 3-1. SUBSATELLITE TRACK

FIGURE 3-2. MERIDIAN OF SENSOR
\[ \beta_c = \sin^{-1} \left[ \frac{R \cos h_c}{r_c} \right] \quad (3.1.33) \]

The angle \( u_c \) and \( k_c \) shown in Figure 3-1 are computed by means of

\[ u_c = \sin^{-1} \left[ \frac{\sin \phi}{\sin i} \right] \quad (3.1.34) \]

and

\[ k_c = \sin^{-1} \left[ \frac{\tan \phi}{\tan i} \right] \quad (3.1.35) \]

The quadrants of \( u_c \) and \( k_c \) are determined by the direction of the pass over the sensor and the signs of the bracketed quantities. The angles \( \Omega \) and \( \omega \) are obtained from

\[ \Omega = \lambda_E - k_c \quad \text{if } i \leq \pi/2 \]
\[ = \lambda_E + k_c \quad \text{if } i > \pi/2 \quad (3.1.36) \]

and

\[ \omega = u_c - v_c \quad (3.1.37) \]

The eccentric anomaly at culmination is obtained from

\[ E_c = \tan^{-1} \left[ \frac{\sin E_c}{\cos E_c} \right] \quad (3.1.38) \]

where

\[ \sin E_c = \frac{\sqrt{1 - e^2} \sin v_c}{1 + e \cos v_c} \quad (3.1.39) \]

and

\[ \cos E_c = \frac{\cos v_c + e}{1 + e \cos v_c} \quad (3.1.40) \]
The orbit epoch is defined at the satellite culmination over the sensor, meridian and

\[ t_o = 0 \]  
\[ \theta_{t_o} = 0 \]  \hspace{1cm} (3.1.41)

\[ M_o = E_c - e \sin E_c \]  \hspace{1cm} (3.1.42)

The computation then continues, as given by ETYPA, to obtain the desired \( M, N \) form.

The fourth option on the element input is converted by ETYPD. This input type defines the elements at a particular range, \( \rho_o \), and elevation angle, \( h_0 \), from a specified sensor. Along with these quantities, the orbital elements \( a, e, i, \Omega, \) and \( \omega \) are also required as input. Initially, the program tests \( \rho_o \) to ensure its validity with respect to the orbit elements. This test is

\[ \rho_{\text{min}} \leq \rho_o \leq \rho_{\text{max}} \]  \hspace{1cm} (3.1.43)

where

\[ \rho_{\text{min}} = q - R \]  \hspace{1cm} (3.1.44)

and

\[ \rho_{\text{max}} = \sqrt{q^2 - R^2} \]  \hspace{1cm} (3.1.45)

Perigee distance, \( q \), and apogee distance, \( q_2 \), in the above equations are obtained from

\[ q = a(1 - e) \]  \hspace{1cm} (3.1.46)

and

\[ q_2 = a(1 + e). \]  \hspace{1cm} (3.1.47)

If \( \rho_o \) is valid, the routine goes on to compute the geocentric distance to the satellite, \( r_o \),

\[ r_o = \sqrt{R^2 + \rho^2 + 2R \rho \sin h_o} \]  \hspace{1cm} (3.1.48)
and the true anomaly

\[ v_0 = \cos^{-1} \left[ \frac{p - e \mathbf{r}_0}{e \mathbf{r}_0} \right], \quad (3.1.49) \]

where \( p \) is computed from Equation (3.1.5), and \( v_0 \) is double valued.

The components of the unit vectors \( \mathbf{P} \) and \( \mathbf{Q} \) in the direction of motion in the orbit plane are computed from

\[
\begin{align*}
\mathbf{P}_x &= \cos \omega \cos \Omega - \sin \omega \sin \Omega \cos i \\
\mathbf{P}_y &= \cos \omega \sin \Omega + \sin \omega \cos \Omega \cos i \\
\mathbf{P}_z &= \sin \omega \sin i
\end{align*}
\]

(3.1.50)

and

\[
\begin{align*}
\mathbf{Q}_x &= - \sin \omega \cos \Omega - \cos \omega \sin \Omega \cos i \\
\mathbf{Q}_y &= - \sin \omega \sin \Omega + \cos \omega \cos \Omega \cos i \\
\mathbf{Q}_z &= \cos \omega \sin i
\end{align*}
\]

(3.1.51)

The components of two \( \mathbf{U} \) vectors are now obtained from the two solutions to \( v_0 \) by

\[
\mathbf{U}_i = \cos v_0 \mathbf{P} + \sin v_0 \mathbf{Q}, \quad (i = 1, 2). \quad (3.1.52)
\]

Auxiliary angles \( \lambda' \), which are the local sidereal times of the station for the solutions of the \( \mathbf{U} \) vectors, are established by

\[
\lambda'_i = \tan^{-1} \left( \frac{\mathbf{U}_y}{\mathbf{U}_x} \right)_i \pm 2 \tan^{-1} \sqrt{K_i}, \quad (i = 1, 2) \quad (3.1.53)
\]

where

\[
K_i = \frac{\sqrt{1 - U^2} \cos \phi + U \sin \phi - \cos \epsilon}{\sqrt{1 - U^2} \cos \phi - U \sin \phi + \cos \epsilon}, \quad (i = 1, 2) \quad (3.1.54)
\]

3-12
FIGURE 3-3.
\[ \cos \epsilon = \frac{R}{r_o - \rho_o \sin h_o} \]  

(3.1.55)

Of the two pairs of possible solutions, one pair is arbitrarily selected and the \( \lambda'_1 \) in which the satellite is entering the field of the sensor is chosen as epoch rather than the one in which it is exiting the field.

The Greenwich sidereal time at epoch for either of the solutions is obtained from

\[ \theta_{t_o} = \lambda'_1 - \lambda_E \]  

(3.1.56)

The eccentric anomaly, \( E_o \), at satellite epoch, \( \theta_{t_o} \), is computed by Equations (3.1.38), (3.1.39), and (3.1.40) (with subscripts c replaced by o). The mean anomaly \( M_o \) is then obtained by

\[ M_o = E_o - e \sin E_o \]  

(3.1.57)

3.1.3 SCHEMATIC COMPUTATIONAL SEQUENCE

As previously mentioned, the programs used in the initializing process are executive subroutines. The major routines ELMRED and SENCARD and their associated routines are described fully in Section 5. The flow diagram of ELMRED is shown here (Figure 3-3) for continuity, since it performs the major initializing function and indicates the role of SENCARD and the associated routines.
3.2 ACQUISITION TIME INTERVALS - AQTINT

The time of satellite acquisition for observation from a given station and sensor is governed by two main considerations. The first consideration is the orbit-plane orientation requirement for sensor visibility, and, secondly, it is desirable to specify the acquisition times in such a manner as to provide flexibility in the sensor's observing schedule. During the first and following passes of the satellite, consistent with an observation duration of selected dates, a specification of the initial and final acquisition times which corresponds to convenient sensor initial and final elevation angles will provide a wide range of observation times. The subdivision of the interval between the initial and final times into observation segments yields several initial and final observation times available for selection according to a desired observation schedule.

3.2.1 AQTINT INPUT-OUTPUT DATA

In the formulation of acquisition times in accordance with the above considerations, it is assumed the following quantities are available as input data:

1. $EBLOC$, the $MN$ satellite orbit elements and sidereal time at satellite epoch.
2. $SBLOC$, sensor identification and sensor station coordinates.
3. $IBLOC$, the initial and final elevation angles convenient for the sensor, total number of observation segments per satellite pass, the segments chosen for observations, and observation time frequency.
4. Time duration of observation.

The output from the program is a block of data, $TBLOC$, consisting of the times of acquisition from each sensor. The individual times depend on the simulation parameters, Item (3), and the number of acquisition times depends on the observation duration; however, the total number of times is limited to approximately 600. An optional feature of the program enables this block of acquisition times to be printed along with each corresponding sensor identification.
3.2.2 AQINT FORMULATION

The task of finding the observation times for a given satellite orbit and station is first concerned with the problem of determining the conditions necessary for the satellite to be above the observer's horizon. The examination of the geometric relationships between the orbit or orientation and position of the observer's station yield the following conditions:

(1) If \( \eta > 1 \) and \( \nu_1 > \nu \)

a portion of the satellite orbit track will always be above the observer's horizon.

(2) If \( \eta_1 > 1 \) and \( \nu_1 < \nu \)

the satellite will never be visible from the station.

(3) If \( \eta_1 < 1 \) or \( \eta < 1 \)

a portion of the satellite orbit path will be above the observer's horizon only when

\[ \nu_1 > \nu \]

The quantities in Equations (3.2.1) through (3.2.4) are defined by the expressions:

\[
\nu = \frac{1}{a(1 + e)} \left( 1 - \frac{a_{x_n}^2 + a_{y_n}^2}{p} \right)^2
\]  

(3.2.5)

\[
\nu_1 = 1 - \frac{(h_x X + h_y Y + h_z Z)^2}{(x^2 + y^2 + z^2)}
\]  

(3.2.6)

\[
\eta_1 = \frac{h_z}{\sqrt{p}} \sin \phi - \sqrt{1 - (h_z)^2/p}
\]  

(3.2.7)
\[
\eta = \frac{\frac{h_z}{p} \sin \phi - \sqrt{1 - \frac{h_z^2}{p}}}{\cos \phi \sqrt{1 - \frac{h_z^2}{p}}}
\]  
(3.2.8)

\[
\nu_2 = \left[ \frac{1 + \sqrt{\frac{a_x n + a_y n^2}{p}}}{p} \right]^2
\]  
(3.2.9)

\[X = -x_c \cos \theta\]  
(3.2.10)

\[Y = -x_c \sin \theta\]

\[Z = -y_c\]

The local sidereal time, \( \theta \), is obtained from

\[
\theta = \theta_{t_0} + \lambda_E + (0.0043752691) t, \quad \text{(3.2.11)}
\]

where \( \theta_{t_0} \) is the sidereal time at epoch from EBLOC, \( \lambda_E \) is the east longitude of the sensor, and \( t \) is time in minutes relative to satellite epoch. If the condition specified by Equation (3.2.3) prevails, then an iterative procedure must be carried out, advancing time, \( t \), until the condition specified by Equation (3.2.4) is fulfilled. The existence of the condition specified by Equation (3.2.4) is guaranteed by the existence of condition (3).

The satellite will be above the horizon upon satisfaction of the inequalities (3.2.1) or (3.2.4) and when

\[
L_{zh} > 0, \quad \text{(3.2.12)}
\]

where

\[
L_{zh} = \frac{1}{\rho} (\rho_x \cos \theta \cos \phi + \rho_y \sin \theta \cos \phi + \rho_z \sin \phi) \quad \text{(3.2.13)}
\]
and

\[ \rho = \sqrt{\rho_x^2 + \rho_y^2 + \rho_z^2} \]  \hspace{1cm} (3.2.14)

The components of \( \rho \) are obtained from

\[ \rho_x = X + x \]  \hspace{1cm} (3.2.15)

\[ \rho_y = Y + y \]

\[ \rho_z = Z + z \]

where \( x, y, \) and \( z \) are obtained from the MNREP subroutine. An iterative procedure must be performed in the time variable, \( t \), until the condition specified by Equation (3.2.12) is fulfilled.

The time, \( t \), corresponding to a given satellite elevation, \( h_{\text{REQ}} \), is determined by the convergence of the following iterative process. A linear approximation to the time interval from the current time point, obtained through condition (3.2.12), to that for \( h_{\text{REQ}} \) is

\[ \Delta t = \frac{(h_{\text{REQ}} - h)\rho}{k_e (\dot{\rho} \cdot \mathbf{h} + \rho \dot{\theta} \mathbf{h})} \]  \hspace{1cm} (3.2.16)

giving the next representation point by means of

\[ t_{\text{NEXT}} = t + \Delta t \]  \hspace{1cm} (3.2.17)
The equatorial system components of \( \mathbf{\hat{h}} \) in Equation (3.2.16) are obtained from the horizon system components by the rotation

\[
\begin{align*}
\mathbf{\hat{h}}_x &= \mathbf{\hat{h}}_{x_h} s_x + \mathbf{\hat{h}}_{y_h} s_y + \mathbf{\hat{h}}_{z_h} s_z \\
\mathbf{\hat{h}}_y &= \mathbf{\hat{h}}_{x_h} s_y + \mathbf{\hat{h}}_{y_h} s_y + \mathbf{\hat{h}}_{z_h} s_z \\
\mathbf{\hat{h}}_z &= \mathbf{\hat{h}}_{x_h} s_z + \mathbf{\hat{h}}_{y_h} s_z + \mathbf{\hat{h}}_{z_h} s_z
\end{align*}
\]  

where

\[
\begin{align*}
\mathbf{\hat{h}}_{x_h} &= \sin h \cos A \\
\mathbf{\hat{h}}_{y_h} &= \sin h \sin A \\
\mathbf{\hat{h}}_{z_h} &= \cos h
\end{align*}
\]

\[
\begin{align*}
S_x &= \sin \phi \cos \theta \\
S_y &= \sin \phi \sin \theta \\
S_z &= -\cos \phi
\end{align*}
\]

\[
\begin{align*}
E_x &= -\sin \theta \\
E_y &= \cos \theta \\
E_z &= 0
\end{align*}
\]
and

\[
\begin{align*}
Z &= \begin{cases} 
Z_x = \cos \phi \cos \theta \\
Z_y = \cos \phi \sin \theta \\
Z_z = \sin \phi 
\end{cases} 
\end{align*}
\]

(3.2.22)

The components of the vector \( \dot{r}_h \) are obtained from

\[
\begin{align*}
\dot{\rho}_x &= -Y \dot{\theta} + \dot{x} \\
\dot{\rho}_y &= X \dot{\theta} + \dot{y} \\
\dot{\rho}_z &= \dot{z},
\end{align*}
\]

(3.2.23)

where \( x, y, \) and \( z \) are available from MNREP, and \( \Theta \) is the rotation rate of the earth. The azimuth, \( A \), and the elevation angle, \( h \), in Equation (3.2.19) are computed from the components of the \( L_h \) vector. These expressions are

\[
h = \tan^{-1} \left[ \frac{L_{zh}}{\sqrt{1 - L_{zh}^2}} \right], \quad 0 \leq h \leq 90^\circ
\]

(3.2.24)

and

\[
A = \tan^{-1} \left[ \frac{L_{yh}}{L_{xh}} \right], \quad 0 \leq A \leq 360^\circ
\]

(3.2.25)
where

\[ L_x = \frac{1}{\rho} \left[ \rho_x \cos \theta \sin \phi + \rho_y \sin \phi \sin \theta - \rho_z \cos \phi \right] \]  

(3.2.26)

\[ L_y = \frac{1}{\rho} (\rho_y \cos \theta - \rho_x \sin \theta) \]  

(3.2.27)

and \( L_z \) is obtained from Equation (3.2.13).

Finally, the initial and final observation times corresponding to the \( i \)th observation segment are obtained from the expressions

\[ t_I = T_I + \frac{(\text{SEGNOs} - 1)}{\text{NUSEG}} (T_F - T_I) \]  

(3.2.28)

and

\[ t_F = T_I + \frac{(\text{SEGNOs}) + n}{\text{NUSEG}} (T_F - T_I) \]  

(3.2.29)

where

\( T_I \) = time in minutes relative to satellite epoch corresponding to the initial elevation angle, \( h_I \).

\( T_F \) = time in minutes relative to satellite epoch corresponding to the final elevation angle, \( h_F \).

\( n \) = number of consecutive segments minus 1.

\( \text{NUSEG} \) = total number of observation segments in one satellite pass.

\( \text{SEGNOs} \) = number, identifying the \( i \)th selection observation segment.

The latter two quantities are inputs, where \( \text{NUSEG} \) may be any number of segments up to a maximum of nine. \( \text{SEGNOs} \) is derived from input specifying any combination of the segments defined by \( \text{NUSEG} \) as is the integer, \( n \).

3.3 OBSERVATION SIMULATION - OBSIM

The purpose of the Observation Simulation Program is to compute topocentric coordinates for a satellite pass over a given set of sensors. It is assumed that acquisition times are provided, along with the time frequency of observations desired during the acquisition interval.

3.3.1 OBSIM INPUT-OUTPUT SPECIFICATIONS

The program requires as input the following quantities:

1. **EBLOC**, elements of the satellite orbit in $M_N$ representation and sidereal time at epoch

2. **SBLOC**, sensor identification and station coordinates of the sensor(s)

3. **TBLOC**, initial and final time limits of the acquisition interval for the sensor, sensor observing frequency, sensor observation type, and maximum range of sensor effectiveness.

The output of the program is the block of data, OBLOC, containing the following information:

- Sensor number (identification)
- Time
- Two angular quantities and/or Range and/or Range rate

The program obtains the simulated observations sensor by sensor. These observations are stored in core to a maximum of 500 points. Any further observations will be punched on observation cards.

3.3.2 OBSIM FORMULATION

The following steps provide the required observation simulation at the points specified by the acquisition interval and the observing frequency for each particular sensor.
The value of the local sidereal time at the required observation time is given by:

\[ \theta = (\theta_{t_0} + \lambda_E) + t (0.0043752691), \]  

(3.3.1)

where \( \lambda_E \) is the east longitude of the station in radians, \( t \) is the current time in minutes relative to the satellite epoch, and \( \theta_{t_0} \) is Greenwich Sidereal time at epoch in radians.

The station position vector components are computed from

\[
\begin{align*}
X &= x_c \cos \theta \\
Y &= x_c \sin \theta \\
Z &= y_c
\end{align*}
\]

(3.3.2)

Obtaining the satellite position vector \((x, y, z)\) from MNREP permits the computation of the range vector

\[
\begin{align*}
\rho_x &= X + x \\
\rho_y &= Y + y \\
\rho_z &= Z + z
\end{align*}
\]

(3.3.3)

and from this, the range to the satellite

\[ \rho = \sqrt{\rho_x^2 + \rho_y^2 + \rho_z^2}. \]  

(3.3.4)

If the sensor has a limited range, \( \rho_{\text{max}} \), then the criterion

\[ \rho < \rho_{\text{max}}. \]  

(3.3.5)

must be satisfied. Also, if the sensor is a visual type, then the following criterion must be fulfilled. The satellite will be visible if illuminated and if the elevation angle of the Sun is negative. The elevation angle of the Sun is negative if, and only if,

\[ \sin h = \left[ -\frac{X L_{x_0} + Y L_{y_0} + Z L_{z_0}}{\sqrt{(x)^2 + (y)^2 + (z)^2}} \right] < 0 \]  

(3.3.6)
The satellite will be illuminated if
\[
\cos \psi = \frac{1}{r} \left( x L_x + y L_y + z L_z \right) \geq 0
\]  
(3.3.7)

and if \( \cos \psi < 0 \), then the satellite will be illuminated if, and only if
\[
r \sqrt{1 - \cos^2 \psi} > 1.
\]  
(3.3.8)

The direction cosines to the Sun are computed by
\[
\begin{align*}
L_x &= \cos \delta_e \cos \alpha_e \\
L_y &= \cos \delta_e \sin \alpha_e \\
L_z &= \sin \delta_e
\end{align*}
\]  
(3.3.9)

where the right ascension of the Sun, \( \alpha_e \), is obtained from
\[
\alpha_e = L_e - C_4 \sin 2 L_e
\]  
(3.3.10)

and the declination, \( \delta_e \), from
\[
\delta_e = \tan^{-1} \left[ C_5 \sin \alpha_e \right].
\]  
(3.3.11)

Equation (3.3.10) requires the current value of the true longitude of the Sun. This is computed from
\[
L_e = L_\circ + C_1 (t + t_0) + C_2 \left[ \sin C_1 (t + t_0) - C_3 \right],
\]  
(3.3.12)

where \( L_\circ \), the mean longitude of the Sun at the beginning of the year in radians, and \(-C_3\), a corrective constant, are obtained from the STLC subroutine. The other constants in Equations (3.3.10), (3.3.11), and (3.3.12) are

\[
\begin{align*}
C_1 &= 0.01720279 \text{ rad/day} \\
C_2 &= 0.0333358 \\
C_4 &= 0.0431096 \\
C_5 &= 0.4336635
\end{align*}
\]
The satellite azimuth and elevation angles are computed from

\[ \phi = \tan^{-1} \left( \frac{L_{y_h}}{L_{x_h}} \right), \quad 0 \leq \phi \leq 2\pi \]  

(3.3.13)

and

\[ h = \sin^{-1} L_z, \quad -\frac{\pi}{2} \leq h \leq \frac{\pi}{2} \]  

(3.3.14)

Equations (3.3.11) and (3.3.12) require the \( L_h \) vector components

\[
\begin{align*}
L_{x_h} &= \frac{1}{\rho} (\rho_x \cos \theta \sin \phi + \rho_y \sin \theta \sin \phi - \rho_z \cos \phi) \\
L_{y_h} &= \frac{1}{\rho} (\rho_y \cos \theta - \rho_x \sin \theta) \\
L_{z_h} &= \frac{1}{\rho} (\rho_x \cos \theta \cos \phi + \rho_y \sin \theta \cos \phi + \rho_z \sin \phi)
\end{align*}
\]  

(3.3.15)

The right ascension and declination may be found from

\[ \alpha = \tan^{-1} \left( \frac{L_y}{L_x} \right), \quad 0 \leq \alpha \leq 2\pi \]  

(3.3.16)

\[ \delta = \sin^{-1} L_z, \quad -\frac{\pi}{2} \leq \delta \leq \frac{\pi}{2} \]  

(3.3.17)

Equations (3.3.16) and (3.3.17) require the \( L \) vector components

\[
\begin{align*}
L_x &= \frac{\rho_x}{\rho} \\
L_y &= \frac{\rho_y}{\rho} \\
L_z &= \frac{\rho_z}{\rho}
\end{align*}
\]  

(3.3.18)
The remaining simulated quantity, range rate, is computed by
\[ \dot{\rho} = L_x (\dot{x} + \dot{x}) + L_y (\dot{y} + \dot{y}) + L_z \dot{z}, \]  
(3.3.19)

where \( \dot{x}, \dot{y}, \) and \( \dot{z} \) are components of satellite velocity obtained from MNREP, and

\[ \dot{x} = -y \dot{\theta} \]
\[ \dot{y} = x \dot{\theta} \]
\[ \dot{\theta} = 0.05883447. \]

3.3.4 OBSIM SCHEMATIC COMPUTATIONAL SEQUENCE

The Observation Simulation flow diagrams are shown in Figures 3-8 and 3-9. The following glossary of terms explains the references made throughout the diagrams to functions presented in the formulation.

RHO Computes $\theta$, $R$, $\rho$ (Equations 3.3.1, 3.3.2, 3.3.3, and 3.3.4).

ANGSUN Computes $h_o$, $\alpha$, $\delta$, $l_e$, $\sin h_o$, $R$ (Equations 3.3.6, 3.3.9, 3.3.10, 3.3.11, and 3.3.12).

LUMANG Computes $\cos \psi$ (Equation 3.3.7).

ELEV Computes $L_h$ (Equation 3.3.15).

AZIM Computes $A$ (Equation 3.3.13).

RTASCN Computes $L$, $\alpha$ (Equations 3.3.16, 3.3.18).

DECLIN Computes $\delta$ (Equation 3.3.17).

RODT Computes $\rho$ (Equation 3.3.19).

3OUTB, OBSOUT Provides OBSIM output according to input options.
FIGURE 3-8. OBSIM
FIGURE 3-9 OBSIM CONT.
3.4 MONTE CARLO - MOCARO

The Monte Carlo, MOCARO, Program Unit is concerned with the generation of sets of contaminated observations from the set of hypothetically true observations. The generation process is based on the hypothesis that the difference between the contaminated and true observations is represented by a random sensor error of fixed standard deviation, \( \sigma_{\text{obs}} \), and a bias error of fixed magnitude. The standard deviation error and bias error are therefore representative of the sensor accuracy.

3.4.1 MOCARO INPUT-OUTPUT DATA

The input data consists of:

1. OBLOC, true observations
2. SGBLOC, sensor standard deviation and bias errors
3. FIRSTRN, first random number used to start the generation of random normal deviates
4. COFLAG, control option to print out contaminated observations
5. \( K \), the number of sets of contaminated observations to be generated.

The output is a block of contaminated observations, COBLOC, containing the information:

Sensor number
Time
Two angular quantities and/or
Range and/or
Range rate
3.4.2 MOCARO FORMULATION *

The contaminated observation, \( \text{OBS}_c \), is obtained by the relationship,

\[
\text{OBS}_c = \text{OBS}_t + \text{BIAS}_\text{OBS} + X_{\text{RN}} \sigma_{\text{OBS}}
\]

where

- \( \text{OBS}_t \) simulated value of the observation from OBLOC
- \( X_{\text{RN}} \) random normal variate
- \( \text{BIAS}_\text{OBS} \) fixed estimate of bias error of the sensor's measurement
- \( \sigma_{\text{OBS}} \) fixed estimate of standard deviation of the sensor's measurement

The random normal variates, \( X_{\text{RN}} \), are obtained by a generation and subsequent transformation of uniform random variates. The generation of uniform random numbers is obtained from the relationship

\[
\begin{align*}
    r_n + 1 &= r_n G, \\ r_n &= r_n \mod 2^{47}
\end{align*}
\]  

(3.4.1)

where \( G \) is a large odd number. The starting random number, \( r_0 \), is of the form,

\[
r_0 = 4K + 1
\]  

(3.4.2)

where \( K \) may be any positive integer. Equation (3.4.1) will produce pseudorandom integers between 0 and \( 2^{47} \). The integers are changed to a more convenient fractional form ranging from 0 to 1 by moving the binary point to the first bit position.

*The procedure for generation of the random normal variate is summarized according to the programming development provided by the H. S. Gelman Co. Limited, Toronto, Canada.*
The transformation from the uniform random variates to standardized ($\sigma = 1, \mu = 0$) normal variates is governed by the relationship,

$$
X_{RN} = \frac{1}{\sqrt{2\pi}} \int_{-\alpha}^{\alpha} e^{-\frac{r^2}{2}} \, dr.
$$

(3.4.3)

Since the closed analytic form of the inverse of this relationship is unknown, a table look-up and interpolation procedure is used to find the normal variates, $X_{RN}$, from the generated uniform variates, $r$.

3.5 DIFFERENTIAL CORRECTION - SGPDC

The purpose of the differential correction program is to determine the sets of orbital elements which individually best represent, in a least squares sense, the corresponding sets of acceptable input observations. This routine is based on the theory of motion in the two-body problem with the optional provision of including the effects of the secular perturbations on the orbital elements produced by the equatorial bulge of the earth and air drag.

The basic computational sequence in the routine consists of:

1. the computation of theoretical observations (either with or without perturbations) at the same time points as the input observations on the basis of a preliminary set of input orbital elements.
2. the formation of observation residuals (observed minus computed).
3. the comparison of the magnitude of the residuals with maximum values beyond which all residuals are rejected.
4. formation of linear correction equations containing the residuals and the element corrections (either with or without perturbations).
5. solution of the least squares matrix of the correction equations for the corrections to the elements.

Following this sequence of computations, the new set of elements are obtained by applying the corresponding corrections to the old set of elements and repeating the above process until the RMS value of the last residuals converge to a desired magnitude considered as acceptable.

The formation of the correction equations is accomplished by use of analytical differential correction formulas. The orbital elements employed in these expressions are:

\[ a = e \mathbf{P}, \] a vector with magnitude of eccentricity, \( e \), directed towards perigee

\[ n, \] the mean motion

\[ U_o = M_o + \omega, \] the mean argument of latitude at arbitrary epoch, \( U_o \), of mean anomaly, \( M_o \), and argument of perigee, \( \omega \)
\( \Omega = \) the nodal longitude \\
\( i = \) orbit inclination \\
\( c'' = \) the drag parameter defined by the equation \\
\[
L = L_o + \left( \frac{dL}{dt} \right)_o (t - t_o) + n_o c'' (t - t_o)^2
\]

where \( L \) is the mean longitude.

The adoption of \( \Omega \) and \( i \) to prescribe the orbit plane orientation and \( U_o \) to denote the initial position at epoch, necessarily restricts the application of the differential correction routine to nonequatorial orbits. The conversion of the input element set to the above form is accomplished within the program.

3.5.1 SGPDC INPUT-OUTPUT DATA

a. Numerical Input

The input observational data accepted by the program may be any combination of the following types:

- Topocentric right ascension, \( \alpha \), and declination, \( \delta \), or azimuth, \( A \), and elevation angle, \( h \).
- Slant range, \( \rho \).
- Slant range rate, \( \dot{\rho} \).

Included with the above observations are the identification number of the observation type, the associated station, and the time of observation. The source of the above observational data is output from the Monte Carlo Error Generator stored in the computer in the contaminated observation block (COBLOC).

The input station coordinates are contained in SBLOC.

The input set of orbital elements are the \( NsM \) type.

\( a_{xN} = \ell \cos \omega \), component of \( a \) along the nodal line.

\( a_{yN} = \ell \sin \omega \), component of \( a \) perpendicular to the nodal line.
\( h = \sqrt{p} \) \( \mathbf{H} \), the orbital angular momentum vector.

\( L_0 = M_o + \omega + \frac{1}{2} \), the mean longitude of the satellite at epoch.

\( C_o \) - the drag parameter defined by the equation:

\[
t = t_o + P_{No} (N - N_o) + C_o (N - N_o)^2
\]

where \( N \) is the revolution number and \( P_{No} \) is the nodal period at satellite epoch.

\( t_o \) - time of satellite epoch.

This input element set is stored in the element block (QBLOC).

b. Program Control Input Data

(1) Perturbation option.

(2) Number of element correction iterations override.

(3) Specific elements to be corrected override.

(4) Residual root-mean-square factor override.

(5) First absolute maximum range and angle residual override.

(6) Second absolute maximum range and angle residual override.

(7) Absolute maximum range rate residual override.

(8) Residual root-mean-square convergence criterion override.

(9) Option to print out variant classical elements and classical delta elements.

(10) Option to print out variant epoch position and velocity and epoch delta position and velocity.

(11) Option to punch out variant classical elements.

(12) Option to punch out variant epoch position and velocity.

3-48
(13) Option to print residual RMS and number of observations used and rejected.

(14) Option to print last iteration residuals.

The above data are inputs to the program via the SGPDC Control card.

c. **Output Data**

1. Variant \textit{N} elements (VEBLOC).
2. Classical delta elements (DEBLOC).
3. Optional output data are listed above (Items 9 through 14) under Program Control Data.

### 3.5.2 SGPDC FORMULATION

The following formulation is intended to serve as description of the fundamental computations in the program and their relation to the program objective, and is not illustrative of the actual computational sequence. The program information flow diagrams (Figures 3-11 through 3-14) describe the details of the complete computational sequence.

**a. Preliminary Calculations**

This part of the program calculates "observations" of the orbit specified by the input set of elements (or subsequently corrected elements) made from the sensor station. Given the station coordinates of latitude, \(\phi\), east longitude, \(\lambda\), and height above sea level, \(H\), and Greenwich sidereal time, \(\Theta\), at satellite epoch, \(t_0\), the following procedure computes the observations \(\rho_c\), \(\rho_c\), and the direction cosines of the unit vector, \(\mathbf{L}\), from the station to the satellite for time, \(t\), relative to satellite epoch.

Compute local sidereal time, \(\Theta\) at time, \(t\),

\[
\Theta = \lambda + \Theta_t + (0.0043752691)t, \text{ (Mod } 2\pi\text{)} \quad (3.5.1)
\]
Compute the station vector, \( \mathbf{R} \),

\[
\begin{align*}
X &= -x_c \cos \theta \\
Y &= -y_c \sin \theta \\
Z &= -y_c
\end{align*}
\]

(3.5.2)

where the \( x, y \) quantities are obtained from (SBLOC) previously stored with the appropriate Station ID.

Compute the slant range, \( \rho_c \),

\[
\rho_c = \sqrt{x^2 + y^2 + z^2}
\]

(3.5.3)

\[
\rho_x = x + X \\
\rho_y = y + X \\
\rho_z = z + Z
\]

(3.5.5)

where \( x, y, z \) are components of \( \mathbf{r} \) obtained from the MNREP subroutine by means of the input elements and the time, \( t \).

Compute unit vector from the station to the satellite in the equatorial coordinate system.

\[
\begin{align*}
L_x &= \frac{\rho_x}{\rho_c} \\
L_y &= \frac{\rho_y}{\rho_c} \\
L_z &= \frac{\rho_z}{\rho_c}
\end{align*}
\]

(3.5.6)

Compute range rate, \( \dot{\rho}_c \),

3-50
SIMULATION ERROR ANALYSIS SYSTEM

\[
\begin{align*}
x &= -y \dot{\theta}, \dot{\theta} = 0.058,834,47 \\
\dot{y} &= x \dot{\theta} \\
\dot{z} &= 0
\end{align*}
\]  

(3.5.7)

\[
\varepsilon_c = \dot{x} + \dot{\theta}.
\]  

(3.5.8)

\[
\rho_c = L \cdot \varepsilon_c = L_x (\dot{x} + \dot{\theta}) + L_y (\dot{y} + \dot{\theta}) + L_z \dot{z},
\]  

(3.5.9)

where \( \dot{x}, \dot{y}, \dot{z} \) are components of \( \dot{\xi} \), obtained from the MNREF subroutine.

b. Residuals

The observation residuals are given by the following expressions. The nonsubscripted symbols denote the input observational quantities, and the subscript \( c \) denotes the above computed observational quantities.

If range \( \rho \), is observed, the residual is:

\[
R_1 = \rho - \rho_c
\]  

(3.5.10)

If azimuth \( A \), and elevation \( h \), are observed, the residuals are, respectively.

\[
\begin{align*}
R_2 &= \rho_c \tilde{A} \cdot (L - L_c) \\
R_3 &= \rho_c \tilde{D} \cdot (L - L_c)
\end{align*}
\]  

(3.5.11) and

(3.5.12)

where

\[
\tilde{A} = \tilde{A}_{xh} S + \tilde{A}_{yh} E + \tilde{A}_{zh} Z
\]  

(3.5.13)

\[
\tilde{D} = \tilde{D}_{xh} S + \tilde{D}_{yh} E + \tilde{D}_{zh} Z
\]  

(3.5.14)

\[
L = L_{xh} S + L_{yh} E + L_{zh} Z
\]  

(3.5.15)
The $S$, $E$, $Z$ unit vector system and the horizon oriented $L_h$, $\tilde{\alpha}_h$, $\tilde{D}_h$ unit vector system are defined by:

$$
\begin{align*}
\begin{cases}
S_x &= \sin \phi \cos \theta \\
S_y &= \sin \phi \sin \theta \\
S_z &= -\cos \phi,
\end{cases}
\end{align*}
$$
(3.5.16)

$$
\begin{align*}
\begin{cases}
E_x &= -\sin \theta \\
E_y &= \cos \theta \\
E_z &= 0,
\end{cases}
\end{align*}
$$
(3.5.17)

$$
\begin{align*}
\begin{cases}
Z_x &= \cos \phi \cos \theta \\
Z_y &= \cos \phi \sin \theta \\
Z_z &= \sin \phi,
\end{cases}
\end{align*}
$$
(3.5.18)

$$
\begin{align*}
\begin{cases}
L_{xh} &= -\cos \alpha \cos h \\
L_{yh} &= \sin \alpha \cos h \\
L_{zh} &= \sin h,
\end{cases}
\end{align*}
$$
(3.5.19)

$$
\begin{align*}
\begin{cases}
\tilde{\alpha}_{xh} &= \sin \alpha \\
\tilde{\alpha}_{yh} &= \cos \alpha \\
\tilde{\alpha}_{zh} &= 0,
\end{cases}
\end{align*}
$$
(3.5.20)

and
\[
\begin{align*}
\bar{x}_h &= \cos A \sin h \\
\bar{y}_h &= -\sin A \sin h \\
\bar{z}_h &= \cos h.
\end{align*}
\] (3.5.21)

If right ascension \(\alpha\), and declination \(\delta\), are observed, the residuals are:

\[
\begin{align*}
R_4 &= \rho_c A \cdot (L - L_c) \\
R_5 &= \rho_c D \cdot (L - L_c)
\end{align*}
\] (3.5.22, 3.5.23)

where

\[
A = \begin{cases}
A_x &= -\sin \alpha \\
A_y &= \cos \alpha \\
A_z &= 0
\end{cases}
\] (3.5.24)

\[
D = \begin{cases}
D_x &= -\sin \delta \cos \alpha \\
D_y &= -\sin \alpha \sin \delta \\
D_z &= \cos \delta
\end{cases}
\] (3.4.25)

\[
L = \begin{cases}
L_x &= \cos \delta \cos \alpha \\
L_y &= \cos \delta \sin \alpha \\
L_z &= \sin \delta
\end{cases}
\] (3.5.26)

If range rate \(\dot{\rho}\), is observed,

\[
R_6 = \rho_c A \dot{\rho} = (\dot{\rho} - \dot{\rho}_c) \rho_c
\] (3.5.27)

3-53
c. **Residual Rejection Test**

After forming a set of residuals corresponding to a set of observations, the magnitudes of the angle and range residuals are compared with an absolute maximum value of 1000 km and the range rate residual is compared with an absolute maximum value of 0.5 km/sec. All residuals exceeding these absolute limits are rejected from the current iteration. Following the above first residual rejection test, a second similar residual rejection test is performed with a new maximum value equal to 1.5 x (RMS value of the previously accepted residuals). The remaining number of residuals are used in the correction Equation (3.5.28). However, upon completion of the calculation of the new set of corrected elements, the absolute maximum value of the first rejection test is subject to a change from 1000 km to 75 km if the new RMS value of the residuals is less than 50 km.

d. **Correction Equations**

This part of the program relates the residuals in the observations at time, $t$, to the corrections to be applied to the initial orbital parameters at epoch, $t_0$. The procedure allows for the calculation of the improved set of orbital elements and quantities associated with the station coordinates at the observation time. The procedure permits the combination of these quantities to obtain coefficients of linear relationships relating residuals to any combination of corrections, $\Delta n, \Delta a_x, \Delta a_y, \Delta U, \Delta \Omega, \Delta i, \Delta c"$. Finally, the corrections to be applied to the elements are determined by solving the (usually over-determined) system of linear correction equations.

The correction equations have the form:

$$
R_i = \sum_{n} (C_{i,n})_n \Delta n_o + \left(\Delta a_x N\right)_i \frac{\Delta a x N_o}{\Delta n_o} + \left(\Delta a_y N\right)_i \frac{\Delta a y N_o}{\Delta n_o} \\
+ \left(\Delta U\right)_i \frac{\Delta U_o}{\Delta n_o} + \left(C_{\Delta \Omega}\right)_i \Delta \Omega_o + \left(C_{\Delta i}\right)_i \Delta i + \left(C_{\Delta c"}\right)_i \Delta c"
$$

(3.5.28)

where the form of the coefficients, $C_i$, depend on the observation type in residual, $R_i$, and time of observation. These coefficients which have been developed by means of first order partials are functions of the orbit elements and computed observations.

The coefficients are computed by first establishing the $R$ and $V$ coefficients at time $t$:
The quantities, $r$, $a$, $a_{xN}$, $e_{yN}$, $e$, $n$, $U$, $e \cos E$, $e \sin E$, $\sin (E + \omega)$, and $\cos (E + \omega)$ are obtained from MNREP subroutine.
When the slant range is observed, the residual and coefficients of Equation (3.5.28) are given by the expressions:

\[ R = R_1 \]  \hspace{1cm} (3.5.31)
\[ C_{\Delta n} = L_c \cdot U_n + L_c \cdot V_u \]  \hspace{1cm} (3.5.32)
\[ C_{\Delta xN} = L_c \cdot U_{xN} + L_c \cdot V_{uN} \]  \hspace{1cm} (3.5.33)
\[ C_{\Delta yN} = L_c \cdot U_{yN} + L_c \cdot V_{yN} \]  \hspace{1cm} (3.5.34)
\[ C_{\Delta u} = L_c \cdot U_u + L_c \cdot V_u \]  \hspace{1cm} (3.5.35)
\[ C_{\Delta \Omega} = L_c \cdot v_r \cos i - L_c \cdot w_r \sin i \cos u \]  \hspace{1cm} (3.5.36)
\[ C_{\Delta i} = L_c \cdot w_r \sin u \]  \hspace{1cm} (3.5.37)
\[ C_{\Delta c''} = L_c \cdot U_c + L_c \cdot V_u \]  \hspace{1cm} (3.5.38)

where \( R_1 \) is given by Equation (3.5.10), \( L_c \) is given by Equation (3.5.6), and the quantities \( U, V, W, \sin u, \) and \( \cos u \) are again obtained by the MNREP subroutine.

When azimuth \( A \) is observed then \( R = R_2 \) as given by Equation (3.5.11), and the coefficients are obtained by replacing \( L_c \), in Equations (3.5.32) through (3.5.38), by \( A \) Equation (3.5.13). Along with azimuth, elevation \( h \) is always observed, and in this case, \( R = R_3 \) as given by Equation (3.5.12), and the corresponding coefficients are obtained by replacing \( L_c \) in Equation (3.5.32) through (3.5.38) with \( h \) Equation (3.5.14).

If right ascension \( \alpha \) is observed then \( R = R_4 \) as given by Equation (3.5.22), and the corresponding coefficients are obtained by replacing \( L_c \) with \( \alpha \) Equation (3.5.24). Along with right ascension, declination \( \delta \) is always observed and in this case, \( R = R_5 \), as given by Equation (3.5.23), and the corresponding coefficients are obtained by replacing \( L_c \) with \( \delta \) Equation (3.5.25).
If range rate, $\dot{\rho}$, is observed, the preliminary coefficients are computed from:

\[
\begin{align*}
\dot{R}_u &= \sqrt{\mu} \frac{a_3}{r^3} (e \cos E - e^2) \\
\dot{R}_n &= \frac{\dot{t}}{3} + (U - U_o) \dot{R}_u \\
\dot{k}_{xN} &= \left(\sqrt{\mu} \frac{a_3}{r^3}\right) \left[ \sin (E + \omega) - a_{xN} e \sin E - a_{yN} \right] \\
\dot{k}_{yN} &= \left(\sqrt{\mu} \frac{a_2}{r^3}\right) \left[ -\cos (E + \omega) - a_{yN} e \sin E + a_{xN} \right] \\
\dot{R}_c &= \frac{2 \dot{R}_n}{n} (U - U_o) \\
\dot{U}_u &= -\sqrt{\mu} \frac{a_2}{r^3} \sqrt{1 - e^2} e \sin E \\
\dot{U}_n &= \frac{\dot{r} u}{3} + (U - U_o) \dot{u}_u \\
\dot{U}_{xN} &= \left(\sqrt{\mu} \frac{a_2}{r^3}\right) \sqrt{1 - e^2} \left[ \cos (E + \omega) - a_{xN} \left(1 + \frac{r^2}{a}\right) \right] \\
\dot{U}_{yN} &= \left(\sqrt{\mu} \frac{a_2}{r^3}\right) \sqrt{1 - e^2} \left[ \sin (E + \omega) - a_{yN} \left(1 + \frac{r^2}{a}\right) \right] \\
\dot{U}_c &= \frac{2 \dot{U}_n}{n} (U - U_o),
\end{align*}
\]
then form the coefficients:

\[
\begin{align*}
\mathbf{c}_{\Delta n} &= L_c \cdot \mathbf{U} \left[ \rho_c \left( \dot{\mathbf{R}}_n - \mathbf{\omega U}_n \right) - \dot{\rho}_c \mathbf{R}_n \right] + \dot{\rho}_c \cdot \mathbf{U} \mathbf{R}_n \\
&\quad + L_c \cdot \mathbf{V} \left[ \rho_c \left( \dot{\mathbf{U}}_n + \frac{\dot{\mathbf{U}}}{r} \mathbf{U}_n \right) - \dot{\rho}_c \mathbf{U}_n \right] + \dot{\rho}_c \cdot \mathbf{V} \mathbf{U}_n \\
(3.5.41)
\end{align*}
\]

\[
\begin{align*}
\mathbf{c}_{\Delta xN} &= L_c \cdot \mathbf{U} \left[ \rho_c \left( \dot{\mathbf{R}}_{xN} - \mathbf{\omega U}_{xN} \right) - \dot{\rho}_c \mathbf{R}_{xN} \right] + \dot{\rho}_c \cdot \mathbf{U} \mathbf{R}_{xN} \\
&\quad + L_c \cdot \mathbf{V} \left[ \rho_c \left( \dot{\mathbf{U}}_{xN} + \frac{\dot{\mathbf{U}}}{r} \mathbf{U}_{xN} \right) - \dot{\rho}_c \mathbf{U}_{xN} \right] + \dot{\rho}_c \cdot \mathbf{V} \mathbf{U}_{xN} \\
(3.5.42)
\end{align*}
\]

\[
\begin{align*}
\mathbf{c}_{\Delta yN} &= L_c \cdot \mathbf{U} \left[ \rho_c \left( \dot{\mathbf{R}}_{yN} - \mathbf{\omega U}_{yN} \right) - \dot{\rho}_c \mathbf{R}_{yN} \right] + \dot{\rho}_c \cdot \mathbf{U} \mathbf{R}_{yN} \\
&\quad + L_c \cdot \mathbf{V} \left[ \rho_c \left( \dot{\mathbf{U}}_{yN} + \frac{\dot{\mathbf{U}}}{r} \mathbf{U}_{yN} \right) - \dot{\rho}_c \mathbf{U}_{yN} \right] + \dot{\rho}_c \cdot \mathbf{V} \mathbf{U}_{yN} \\
(3.5.43)
\end{align*}
\]

\[
\begin{align*}
\mathbf{c}_{\Delta u} &= L_c \cdot \mathbf{U} \left[ \rho_c \left( \dot{\mathbf{R}}_u - \mathbf{\omega U}_u \right) - \dot{\rho}_c \mathbf{R}_u \right] + \dot{\rho}_c \cdot \mathbf{U} \mathbf{R}_u \\
&\quad + L_c \cdot \mathbf{V} \left[ \rho_c \left( \dot{\mathbf{U}}_u + \frac{\dot{\mathbf{U}}}{r} \mathbf{U}_u \right) - \dot{\rho}_c \mathbf{U}_u \right] + \dot{\rho}_c \cdot \mathbf{V} \mathbf{U}_u \\
(3.5.44)
\end{align*}
\]

\[
\begin{align*}
\mathbf{c}_{\Delta \Omega} &= - \rho_c L_c \cdot \mathbf{U} \mathbf{r} \mathbf{\omega} \cos i + L_c \cdot \mathbf{V} \cos i \left[ \rho_c \mathbf{r} - \dot{\rho}_c \mathbf{r} \right] \\
&\quad + \dot{L}_c \cdot \mathbf{V} \mathbf{r} \cos i + \dot{L}_c \cdot \mathbf{W} \sin i \left[ \rho_c \left( \mathbf{r} \mathbf{\omega} \sin u - \frac{\dot{\mathbf{r}}}{r} \cos u \right) \right] \\
&\quad + \dot{\rho}_c \mathbf{r} \cos u - \dot{\rho}_c \mathbf{r} \sin i \cos u \\
(3.5.45)
\end{align*}
\]

3-58
\[
C_{\Delta 1} = L_c \cdot W \left[ \rho_c \left( r \dot{\psi} \cos u + t \sin u \right) - \dot{\rho}_c r \sin u \right] + \dot{\rho}_c \cdot W r \sin u
\]

(3.5.46)

\[
C_{\Delta c''} = L_c \cdot W \left[ \rho_c \left( \dot{R}_c - \dot{\psi} U_c \right) - \dot{\rho}_c R_c \right] + \dot{\rho}_c \cdot U R_c
\]

+ \dot{L}_c \cdot W \left[ \rho_c \left( \dot{U}_c + \frac{t}{r} U_c - \dot{\rho}_c U_c \right) + \dot{\rho}_c \cdot U U_c \right],
\]

(3.5.47)

where \( R_c \), given by Equation (3.5.27), is the corresponding residual for the above coefficients. The correction equation is formed as an Equation (3.5.28).

Considering all of the correction Equations (3.5.28) let:

\[
\sum_{i=1}^{N} C_{ij} \Delta_i = R_{ij}
\]

represent all such equations where: \( C_{ij} \)'s are the coefficients, \( R_{ij} \)'s are the accepted observation residuals, \( \Delta_i \)'s are the corrections to the orbital elements, and \( N \) is the number of elements to be corrected and \( j \) is the number of accepted observation residuals. The resulting matrix equation is solved to give the corrections, \( \Delta_i \)'s, in a least square sense, to the orbital elements at time, \( t_0 \). These corrections are applied as follows (primes denote corrected elements):

\[
n_0' = n_0 \left( 1 + \frac{\Delta n_0}{n_0} \right)
\]

(3.5.48)

\[
(c'')' = c'' + \Delta c''
\]

(3.5.49)

\[
c_o' = - \left( \frac{(c'')'}{n_0^2} \left( \frac{\pi^2}{360} \right) \right)
\]

(3.5.50)

\[
U_o' = U_o + \Delta U_o
\]

(3.5.51)

\[
a_{xN0}' = a_{xN0} + \Delta a_{xN}
\]

(3.5.52)
Following the above calculation of the corrected elements, a representation of the observations is performed on the basis of the corrected elements, and another set of residuals are formed by using the same input observations. The RMS values of the last two sets of consecutive residuals are compared to insure convergence of the computational process. The process is complete when the residual RMS converges to the minimum value considered as acceptable.

FIGURE 3-13. SGPDC (Continued)
RPT  Number of iterations per element correction specification.

SUM  Sum of squares of good range and angle residuals.

MAX  Current maximum value of acceptable range and angle residual RMS.

MAX 2 Current maximum value of acceptable range rate residual RMS.

XISTSG RMS multiplication factor.

XJGRCF Perturbation control.

ALREC Computes A, D and L from right ascension and declination observations.

AZREC Computes \( \hat{A}, \hat{D} \) and L from azimuth and elevation observations.

CCIN Tests the overrides input on the SGPDC control card and initializes the DC accordingly. CCIN uses SETJC to initialize perturbations.

CEILMSB Converts N, M elements to classical and stores them in CEBLOC (element type A and B only). The following formulas are used:

\[
\begin{align*}
P_o &= h_x^2 + h_y^2 + h_z^2 \\
W_o &= \frac{h_o}{P_o} \\
\Omega_o &= \tan^{-1} \left( \frac{W_x}{W_y} \right) \\
\end{align*}
\]

3-67
\[ e^2 = a_x^2 + a_y^2 \]
\[ e = \left( \frac{P_0}{1 - e^2} \right)^{1/2} \]
\[ \omega = \tan^{-1} \frac{a_y}{a_x} \]

- if \( W_z > 0 \), direct motion

\[ M = L_0 + \Omega_0 - \omega \]

+ if \( W_z < 0 \), retrograde motion

\[ c = c_0 \]

CMPCF Computes coefficients \( C \) (of Equation 3.5.28) for range and angle observations.

COMDEL Computes \( \Delta L, \Delta \bar{L} = L - L_c \) with \( L \) from Equation 3.5.14 or 3.5.26.

COMRMS Computes RMS of acceptable observations.

COMXLX Computes \( L_c \), Equation 3.5.6.

CORRD Computes coefficients \( C \) (Equation 3.5.28) for range rate observations.

CREKT Computes the corrected elements (Equation 3.5.48).

DELTau Computes geocentric angle between observed and computed satellite position vector, \( \Delta U \).

\[ \Delta u = \tan^{-1} \left[ \frac{(U \times \hat{r}_{obs}) \cdot \hat{W}}{U \cdot \hat{r}_{obs}} \right] \]

DOTPR Computes vector dot products of \( U, V \) and \( W \) with any of \( L_c, A, \bar{A}, D \) or \( \bar{D} \).
GENDEL

Generates delta classical elements according to the following formulas:

\[ \omega' = \tan^{-1} \frac{a'_y / yN_0}{a'_x / xN_0} \]

\[ M'_0 = L'_0 + \Omega'_0 - \omega'_0 \begin{cases} -\Omega'_0 & \text{if } W_z \geq 0 \\ \omega'_0 + \Omega'_0 & \text{if } W_z < 0 \end{cases} \]

\[ \Delta a_o = a'_o - a_o \]

\[ \Delta e_o = e'_o - e_o \]

\[ \Delta i_o = i'_o - i_o \]

\[ \Delta \Omega_o = \Omega'_o - \Omega_o \]

\[ \Delta \omega_o = \omega'_o - \omega_o \]

\[ \Delta M_o = M'_o - M_o \]

\[ \Delta c_o = c'_o - c_o \]

Note: Prime indicates variant element set.

All \( \Delta \) angles are mod \( 2\pi \).

If the corresponding element has no correction specified, the delta element is set to 0.

MOVDATI

Retrieves one processed observation from POBLOC.

MOVDATI has a special return for end of observations.

OBVEC

Computes \( \theta, X, Y \).

OBVECP

Moves station number, observation type, time since epoch, and \( X, Y, Z \) into POBLOC.

OBVECQ

Moves \( A \) or \( \bar{A} \), \( D \) or \( \bar{D} \) and \( L \) into POBLOC.

3-69
PUNCHTA Punches Type A variant element cards 1 and 2. (See card formats).

PUNCHTB Uses common subroutine MNREF to compute $r$, $\theta$ elements at epoch and punches Type B variant element cards 1 and 2. (See card formats).

RDTSB Computes $\rho_c$, $\rho_c^*$, Equations 3.5.8 and 3.5.9.

RESREJ1 Rejects range and angle observation if residual is greater than MAX and accumulates a count of acceptable and unacceptable observations; also, computes the sum of squares of acceptable residuals.

RESREJ2 Same as RESREJ1 except rejects range rate observation greater than MAX2.

RESTELT Restores an element set from the SVELT buffer. (See SAVELT for contents).

RHOSB Computes $\rho_c$, Equation 3.5.3.

RRATE Computes $R$, Equation 3.5.7.

SAVELT Saves a corrected element set in SVELT buffer. This includes the following: $a_xN_0$, $a_yN_0$, $h_x$, $h_y$, $L_o$, $c_o$, rms for range and angles, $y_o$, $z_o$, $\Delta N_0$, $\Delta a_xN_0$, $\Delta a_yN_0$,$\Delta U_o$, $\Delta \Omega, \Delta i, \Delta c^\prime$, number of acceptable residuals, number of residuals rejected, number of elements corrected.

SRESOUT Uses program subroutine COMRMS to compute the RMS's and outputs them in addition to the count of the residuals accepted and rejected.

SRSOUTI Performs the following:

(1) Computes vector magnitude

(2) Computes $r_{obs}$
(3) Uses DELTAU (program subroutine) to compute \( \Delta u \).

(4) Computes:
\[
U = U_c + \Delta u, \quad \Delta t = \frac{r^2 \Delta u}{k e \sqrt{p}}
\]
\[
\beta = \sin^{-1} \left( \frac{\frac{r_{\text{obs}}}{r_{\text{obs}}}}{W} \right)
\]

(5) Outputs: Station ID, time residuals, rejection flags, vector magnitude, \( \Delta t \), \( U \), \( \beta \).

- TARITE: Uses common subroutine ELOUTA to print classical elements in EBUF.
- TASET: Saves classical elements: \( a_o, e_o, i_o, \Omega_o, \omega_o, M_o, C_o, t_o \) in EBUF for output.
- TBRITE: Uses ELOUTB to print \( \hat{\mathbf{r}}, \hat{\mathbf{f}} \) elements in EBUF and prints \( \Delta \hat{\mathbf{r}}, \Delta \hat{\mathbf{f}} \) elements in EBUFD.
- TBSET: Uses common subroutine MNREP to compute \( \hat{\mathbf{r}}, \hat{\mathbf{f}} \) at epoch and saves the following in EBUF: \( x, y, z, \dot{x}, \dot{y}, \dot{z}, C_o, t \). Also computes \( \Delta \hat{\mathbf{r}}, \Delta \hat{\mathbf{f}} \) elements and saves them in EBUFD.
- ZDCOUT: Outputs comments indicating perturbation type used in SGPDC.
3.6 ELEMENT DISTRIBUTION - DCDIST

Statistical processing of the delta elements generated by the Differential Correction Program Unit is the function of the DCDIST Program Unit. The delta elements generated by SGPDC are the differences between the variant element sets and the reference element set. These differences represent, within the sensor error model chosen, errors in the determination of orbital elements.

3.6.1 DCDIST INPUT-OUTPUT DATA

The input data, DEBLOC, consist of K sets of the quantities, \( \Delta a, \Delta e, \Delta i, \Delta \Omega, \Delta \omega, \Delta M_0 \), and possibly \( \Delta C_0 \).

The DCDIST control parameters, input via the SPGDC control card, consist of:

- **DCNS**: The number of samples of an element error used to compute the mean and standard deviation error.
- **DCI**: The number of cells in each element frequency distribution.
- **DCSL**: The number of standard deviations below the mean at the first cell of the element frequency distributions.
- **DCS2**: The number of standard deviations above the mean at the last cell of the element frequency distributions.
- **DCCCPI**: Control parameter from SGPDC indicating which elements have simulated errors.
- **DCCCP3**: Control parameter from SGPDC indicating perturbation analysis option.
- **DCCCP10**: Classical element distribution suppression.
The output from DCDIST routine contains a printed listing of the following statistical data:

- Identification of error quantity
- Mean
- Standard deviation
- Minimum error, MIN
- Maximum error, MAX
- Summation of DCNS errors
- Summation of the square of DCNS errors
- DCNS
- Total number of errors, N
- DCS1
- DCS2
- Frequency distribution
- Lower limit of the frequency distribution
- Cell width of the frequency distribution

3.6.2 DCDIST FORMULATION

The presentation of the computations in the DCDIST Unit is given under Common Subroutine, STOB.

3.7 ERROR PREDICTION - ERP

The purpose of the Error Prediction Program Unit is to compute the errors in position and velocity at specified points due to variations in the orbit elements established in the MOCARO-SGPDC loop. The unit is functionally connected to the Prediction Distribution Program Unit and the two units are referred to in the executive logic as ERPRED. This functional connection is necessary because of the quadrant, or segment, prediction analysis specification for the system. In response to this system function, the two units were designed to provide compatible interfaces and thus act as two large subroutines under the control of an executive driver. However, for logical presentation of the system components, these two units are discussed separately.

Several modes of operation are available for the Error Prediction Program Unit. These likewise apply to the combined ERPRED function. The modes of operation are:

(1) **Specification of points for evaluation of errors, designated by Casetype, an integer from 0 to 3.**

(a) Casetype = 0: The prediction points are equally spaced in mean anomaly, \( M \), and are referenced to the first perigee passage after epoch. \( P_1 = \text{initial} \, M \), \( \Delta P = \Delta M \), and \( P_f = \text{final} \, M \). Note: If the eccentricity is too small, then these data are automatically assumed to be \( U \) data, mean latitude and a printout is made indicating this.

(b) Casetype = 2: There are \( N \) equally spaced points in each of the four quadrants of mean anomaly, \( M \), following the time of the last observation. \( P_1 = N \). (\( \Delta P \) and \( P_f \) not used).

(c) Casetype = 3: The prediction points are equally spaced in time referenced to epoch. \( P_1 = \text{initial time} \, P = \Delta t \), \( P_f = \text{final time} \).

(2) **Specification of form of output**

(a) If OTPFLAG = 0, then the position and velocity errors are referenced to the \( x, y, z \) coordinate system.
(b) If OTPFLAG ≠ 0, then the position and velocity errors are referenced to the U, V, W coordinate system.

(3) Specification of Method of Computation

(a) If APMFLAG = 0, then the errors are computed by representing the variant orbits using MNREP and subtracting the reference orbit position and velocity. In this mode, the perturbation control on MNREP is that assigned to the system in initialization.

(b) If APMFLAG = 1, then the errors are computed using MNREP with perturbations, overriding the system control.

(c) If APMFLAG = 2, then the errors are computed using MNREP without perturbations, overriding the system control.

(d) If APMFLAG = 3, then the errors are computed by multiplying the errors in the element set by a matrix of partial derivatives (Linear Taylor's expansion).

3.7.1 ERP INPUT-OUTPUT DATA

The input system and control data include:

(1) Operating Mode Indicators

  CASETYP
  APMFLAG
  OTPFLAG

(2) Prediction Points

  \( P_i, \Delta P, P_f \)

  Number of variant element sets = \( k \)
(3) Reference Element Set

\[ L_0, a_{x0}, a_{y0}, h_x, h_y, h_z, t_0 (EPOCH), c_0 \]

(4) Variant Element Sets

DEBLOC (\( \Delta a_j, \Delta e_j, \Delta i_j, \Delta o_j, \Delta \omega_j, \Delta M_{oj}, \Delta C_{oj} \))

VEBLOC (\( L_{oj}, a_{xoj}, a_{yoj}, h_{xoj}, h_{yoj}, h_{zoj} \))

The reference element set, delta element sets, and variant element sets are available from stored data blocks, EBLOC, DEBLOC, and VEBLOC, respectively. The remaining input data enter the routine via the error prediction card.

The output data are contained in DFVBLOC and consist of either delta position and velocity in equatorial coordinates

\[ \Delta x, \Delta y, \Delta z, \Delta \dot{x}, \Delta \dot{y}, \Delta \dot{z}, |\Delta \dot{X}|, |\Delta \dot{Z}| \]

or orbital coordinates

\[ D_u, D_v, D_w, \dot{D}_u, \dot{D}_v, \dot{D}_w, |\Delta \dot{X}|, |\Delta \dot{Z}| \]

3.7.2 ERP FORMULATION

(1) Compute \( e_o^2 \):

\[
e_o^2 = a_{x0}^2 + a_{y0}^2 \tag{3.7.1}
\]

(2) Compute \( \omega_o \) and \( \Omega_o \):

\[
\omega_o = \tan^{-1} \frac{a_{y0}}{a_{x0}} \tag{3.7.2}
\]

*In expressions using the arctan, the quadrant is determined by inspection of the numerator and denominator.

3-79
\[ \Omega_0 = \tan^{-1} \frac{h_x}{-h_y} \quad (3.7.3) \]

(3). Compute \( \Omega_0 \):

\[ \Omega_0 = \tan^{-1} \frac{h_x}{-h_y} \quad (3.7.4) \]

(4) Compute \( t_i, \Delta t, t_f \) from \( P_i \): \((N \text{ is stored in } P_i)\)

\[ t_{\text{OFB}} = \text{time of last observation} \]

\[ t_i = t_{\text{OFB}} - t_o \quad (3.7.5) \]

\[ p_o = h_{x_o}^2 + h_{y_o}^2 + h_{z_o}^2 \quad (3.7.6) \]

\[ a_o = p_o / (1 - e_o^2) \quad (3.7.7) \]

\[ \Delta t = \frac{\pi a_o^{3/2}}{2 P_i k e^{\sqrt{\mu}}} \quad (3.7.8) \]

\[ t_f = \frac{2 \pi a_o^{3/2}}{k e^{\sqrt{\mu}}} + t_{\text{OFB}} - t_o \quad (3.7.9) \]

(5) Initial Quadratic Coefficients for \( U \) \((a, b, \text{and } c)\):

\[ n_o = \frac{k e^{\sqrt{\mu}}}{a_o^{3/2}} \quad (3.7.10) \]
(a) If XJGRCF = 0 (no perturbations), then

\[ a = 0 \]

\[ b = n_0 \]

\[ c = L_0 - P_1 - \frac{h_0}{h_0} \Omega_0 \]

(b) If XJGRCF ≠ 0 (perturbations), then

\[ c'' = \frac{360n_0^2c_0}{\pi^2} \]

\[ J' = \sqrt{\mu} \frac{J_a e}{p_0} 7/2 \]

\[ a = c'' \left( n_0 + k_e J' \frac{h_0}{\sqrt{p_0}} 4. e_0 (1-e_o) \right) \]

\[ b = n_0 + k_e J' \left[ -1 + \frac{7}{4} e_0^2 + \frac{h_0^2}{p_0} (4 - \frac{27}{4} e_0^2) \right] \]

\[ c = L_0 - P_1 - \frac{h_0}{h_0} \Omega_0 \]

(6) Initial Quadratic Coefficients for M (a, b, and c):

(a) If XJGRCF = 0 (no perturbations), then

\[ a = 0 \]

\[ b = n_0 \]
\[ c = L_0 - P_i - \omega_0 - \frac{h_{z_0}}{|h_{z_0}|} \Omega_0 \]

(b) If \( XIGRCF \neq 0 \) (perturbations), then

\[
c'' = - \frac{360 n^2 c_o}{\pi^2} \]
\[
J' = \frac{\sqrt{\mu} J a e^2}{p_o^{7/2}}
\]

\[
a = c'' \left[ n_o + 2k e J 'e_o (1 - e_o) \right] \left\{ 1 + 2 \frac{h_{z_o}}{\sqrt{p_o}} - 5 \frac{h_{z_o}^2}{p_o} \right\}
\]
\[
b = n_o - k e J ' \left( \frac{1}{2} - e_o^2 \right) \left( 1 - 3 \frac{h_{z_o}^2}{p_o} \right)
\]
\[
c = L_0 - P_i - \omega_0 - \frac{h_{z_0}}{|h_{z_0}|} \Omega_0
\]

(7) Solve quadratic equation for \( t_n \):

(a) If \( \left| \frac{4ac}{b^2} \right| \geq \delta_2 \), then

\[
t_n = - \frac{b}{2a} \left\{ 1 - \sqrt{1 - \frac{4ac}{b^2}} \right\} \quad (3.7.11)
\]

(b) If \( \left| \frac{4ac}{b^2} \right| \leq \delta_2 \), then

\[
t_n = - \frac{c}{b} \left( 1 + \frac{ac}{b^2} \right) \quad (3.7.12)
\]

3-82
(c) If \((1 - \frac{4ac}{b^2}) \leq 0\) then

\[ t_n = -\frac{b}{2a} \]  

(3.7.13)

Print: NEGATIVE RADICAND EQUALS - .rrr ± ee
Continue processing

(8) Compute Partial Derivative Matrix \([p_{ij}]\), where

\[
\begin{align*}
\quad P_{11} &= R_m \\
\quad P_{12} &= R_{xN} \\
\quad P_{13} &= R_{yN} \\
\quad P_{14} &= \frac{a}{a} \\
\quad P_{15} &= P_{16} = 0 \\
\quad P_{21} &= V_m \\
\quad P_{22} &= V_{xN} \\
\quad P_{23} &= V_{yN} \\
\quad P_{24} &= \frac{a}{a} \\
\quad P_{25} &= 0 \\
\quad P_{26} &= r \cos i \\
\quad P_{31} &= P_{32} = P_{33} = P_{34} = 0 \\
\quad P_{35} &= r \sin u 
\end{align*}
\]

3-83
\[ p_{36} = -r \sin i \cos u \]
\[ p_{41} = R_x - \dot{\nu} V_m \]
\[ p_{42} = R_x - \dot{\nu} V_{xN} \]
\[ p_{43} = R_y - \dot{\nu} V_{yN} \]
\[ p_{44} = (\dot{R}_a - \dot{\nu} V_a) / a \]
\[ p_{45} = 0 \]
\[ p_{46} = -r \dot{\nu} \cos i \]
\[ p_{51} = \dot{V}_m + \dot{\nu} V_m \]
\[ p_{52} = V_{xN} + \dot{\nu} V_{xN} \]
\[ p_{53} = V_{yN} + \dot{\nu} V_{yN} \]
\[ p_{54} = (\dot{V}_a - \dot{\nu} V_a) / a \]
\[ p_{55} = 0 \]
\[ p_{56} = \dot{r} \cos i \]
\[ p_{61} = p_{62} = p_{63} = p_{64} = 0 \]
\[ p_{65} = r \dot{\nu} \cos u + \dot{r} \sin u \]
\[ p_{66} = (r \dot{\nu} \sin u - \dot{r} \cos u) \sin i \]

The auxiliary quantities in the \( p_{ij} \) elements are obtained from:

3-84
\[ R_m = \frac{a^2}{r} \sin E \] (3.7.14)

\[ R_a = r - \frac{3}{2} (U - U_o) R_m \] (3.7.15)

\[ R_{xN} = \frac{a^2}{r} \left[ a_{xN} \cos (E + \omega) \right] \] (3.7.16)

\[ R_{yN} = \frac{a^2}{r} \left[ a_{yN} \sin (E + \omega) \right] \] (3.7.17)

\[ V_m = \frac{a^2}{r} - \sqrt{1-e^2} \] (3.7.18)

\[ V_a = -\frac{3}{2} (U - U_o) V_m \] (3.7.19)

\[ V_{xN} = \frac{a^2}{r} \left[ (1 + \frac{r}{a}) \sin (E + \omega) \right. \] (3.7.20)

\[ + a_{xN} \sin E \frac{e^2 - (1+ \sqrt{1-e^2}) \cos E}{\sqrt{1-e^2} (1+ \sqrt{1-e^2})^2} \]

\[ - \frac{a_{yN}}{1+\sqrt{1-e^2}} \right] \]

\[ V_{yN} = \frac{a^2}{r} \left[ - (1 + \frac{r}{a}) \cos (E + \omega) \right. \] (3.7.21)

\[ + a_{yN} \sin E \frac{e^2 - (1+ \sqrt{1-e^2}) \cos E}{\sqrt{1-e^2} (1+ \sqrt{1-e^2})^2} \]

\[ + \frac{a_{xN}}{1+\sqrt{1-e^2}} \right] \]

\[ R_m = \sqrt{\mu a^{5/2}} \frac{(e \cos E - e^2)}{r^3} \] (3.7.22)

3-85
\[ R_x = -\frac{1}{2} \dot{r} - \frac{3}{2} (U - U_o) \frac{\dot{r}}{r} \]  
(3.7.23)

\[ R_{xN} = \sqrt{\mu} a^{5/2} \left[ \sin (E + \omega) - a_{xN} \sin E - a_{yN} \right] / r^3 \]  
(3.7.24)

\[ R_{yN} = \sqrt{\mu} a^{5/2} \left[ -\cos (E + \omega) - a_{yN} \sin E + a_{xN} \right] / r^3 \]  
(3.7.25)

\[ V_m = \sqrt{\mu} a^{5/2} \sqrt{1-e^2} \sin E / r^3 \]  
(3.7.26)

\[ V_a = -\frac{1}{2} \dot{r} \dot{\theta} - \frac{3}{2} (U - U_o) \frac{\dot{r}}{r} \]  
(3.7.27)

\[ V_{xN} = \sqrt{\mu} a^{5/2} \sqrt{1-e^2} \left[ \cos (E+\omega) - a_{xN} \left(1+\frac{\dot{r}}{\dot{a}}\right) \right] / r^3 \]  
(3.7.28)

\[ V_{yN} = \sqrt{\mu} a^{5/2} \sqrt{1-e^2} \left[ \sin (E+\omega) - a_{yN} \left(1+\frac{\dot{r}}{\dot{a}}\right) \right] / r^3 \]  
(3.7.29)

The parameters which are used in the above expressions are available from the MNREP subroutine.

(9) Compute U, V, W errors using Partial Matrix:

\[
\begin{bmatrix}
D_u \\
D_v \\
D_w \\
D_u \\
D_v \\
D_w \\
\end{bmatrix}
= \begin{bmatrix}
P \\
n \\
\end{bmatrix} x
\begin{bmatrix}
\Delta U_o \\
\Delta a_{xN} \\
\Delta a_{yN} \\
\Delta a \\
\Delta i \\
\Delta \Omega \\
\end{bmatrix}
\]

(3.7.30)
(10) Convert \( U, V, W \) errors to \( x, y, z \) errors:

\[
\begin{align*}
\Delta x &= D_u U_x + D_v V_x + D_w W_x \\
\Delta y &= D_u U_y + D_v V_y + D_w W_y \\
\Delta z &= D_u U_z + D_v V_z + D_w W_z \\
\Delta \dot{x} &= \dot{D}_u U_x + \dot{D}_v V_x + \dot{D}_w W_x \\
\Delta \dot{y} &= \dot{D}_u U_y + \dot{D}_v V_y + \dot{D}_w W_y \\
\Delta \dot{z} &= \dot{D}_u U_z + \dot{D}_v V_z + \dot{D}_w W_z
\end{align*}
\]

(3.7.31)

(11) Convert \( x, y, z \) errors to \( U, V, W \) errors:

\[
\begin{align*}
D_u &= \Delta x U_x + \Delta y U_y + \Delta z U_z \\
D_v &= \Delta x V_x + \Delta y V_y + \Delta z V_z \\
D_w &= \Delta x W_x + \Delta y W_y + \Delta z W_z \\
\dot{D}_u &= \Delta \dot{x} U_x + \Delta \dot{y} U_y + \Delta \dot{z} U_z \\
\dot{D}_v &= \Delta \dot{x} V_x + \Delta \dot{y} V_y + \Delta \dot{z} V_z \\
\dot{D}_w &= \Delta \dot{x} W_x + \Delta \dot{y} W_y + \Delta \dot{z} W_z
\end{align*}
\]

(3.7.32)

(12) Compute \(|\Delta \xi|, |\Delta \dot{\xi}|\):

\[
|\Delta \xi| = \left[ (\Delta x^2 + \Delta y^2 + \Delta z^2) \right]^{1/2} \quad (3.7.33)
\]

\[
|\Delta \dot{\xi}| = \left[ (\Delta \dot{x}^2 + \Delta \dot{y}^2 + \Delta \dot{z}^2) \right]^{1/2} \quad (3.7.34)
\]
or

\[ |\Delta r| = \left( D_u^2 + D_v^2 + D_w^2 \right)^{1/2} \quad (3.7.35) \]

\[ |\Delta \xi| = \left( \dot{D}_u^2 + \dot{D}_v^2 + \dot{D}_w^2 \right)^{1/2} \quad (3.7.36) \]

Those equations are used for which the data are available.

### 3.7.4 ERP SCHEMATIC COMPUTATIONAL SEQUENCE

The Error Prediction diagram showing the program logic is presented in Figure 3-16. A glossary of the main internal subroutines used in the diagram is given below for reference:

- **MATRIX** Computes the coefficients of the matrix (Step 8).
- **XMATRIX** Solves Equation 3.7.30.
- **DU2DX** Converts $D_u, D_v, D_w$ errors to $\Delta x, \Delta y, \Delta z$ using Equations 3.7.31.
- **SAVDE** Computes $|\Delta x|$ and $|\Delta y|$ using Equations 3.7.33, 3.7.34 or Equations 3.7.35, 3.7.36, storing in DPVBLOC.
- **QUADEQ** Computes $t_n$ using Equations 3.7.11, 3.7.12, 3.7.13.
- **CASE2** Computes $t_f$, $\Delta t$, $t_f$ (Equations 3.7.5, 3.7.8, 3.7.9).
- **QUADCO** Computes $a$, $b$, $c$ for Equations 3.7.11, 3.7.12, 3.7.13.
- **INIT1** Computes $e_0^2$, $e_o$, $P_0$.
- **COMDEL** Computes $\Delta a/a$, $\Delta \omega$, $\Delta a_{XN}$, $\Delta a_{YN}$.
- **REPSUB** Uses MNREP to compute $\Delta x, \Delta y, \Delta z, \Delta \dot{x}, \Delta \dot{y}, \Delta \dot{z}$ at time $t$.

The diagram in the upper portion of Figure 3-16 illustrates the complete looping sequence of operations between ERP and ERPDIST. This represents the ERPRED function described above.
3.8 PREDICTION DISTRIBUTION - ERPDIST

The Prediction Distribution Program Unit, ERPDIST, performs the statistical processing of the delta position and velocity data generated by the ERP Program Unit. The delta position and velocity data generated by ERP are the differences in the predicted position and velocity vectors produced by the variant element sets and the reference element set. These differences constitute the sets of position and velocity vector errors arising from the simulated observational inaccuracies.

The purpose of the ERPDIST Unit is to compute at each prediction point a statistic of each coordinate of position and velocity. The statistic of the errors include the maximum, minimum, mean, standard deviation, and at option a frequency distribution of the errors. Also, for all prediction points in a quadrant (beginning at the last observation), the statistic of each coordinate at each prediction point will be treated as a set of error quantities, and for each of these corresponding error quantities, a statistic will be computed for that quadrant of the orbit. The process is repeated for the remaining quadrants.

3.8.1 ERPDIST INPUT-OUTPUT DATA

The statistical processing of position and velocity errors require the following input data:

(1) DPVBLOC, the k sets of delta position and velocity error data:

\[
\begin{align*}
\Delta x & \text{ or } D_u \\
\Delta y & \text{ or } D_v \\
\Delta z & \text{ or } D_w \\
|\Delta r| & \\
|\Delta t| & 
\end{align*}
\]

These error quantities are output from the Error Prediction Program Unit and are either in equatorial or orbit plane coordinates respectively.

(2) ERPNS The number of samples of a position-velocity type error used to compute the mean and standard deviation.
(3) QUNS  The number of samples of the error quantity used to compute the mean and standard deviation in the quadrant and analysis.

(4) ERPM  The number of cells in the position-velocity coordinate frequency distributions.

(5) ERPS1  The number of standard deviations below the mean at the first cell of the position-velocity coordinate frequency distribution.

(6) ERPS2  The number of standard deviations above the mean at the last cell of the position-velocity coordinate frequency distribution.

(7) OTPFLAG Control parameter from ERP defining either equatorial or orbit plane coordinates in DPVBLOC.

(8) CASETYP Control parameter from ERP indicating the option to perform or exclude quadrant analysis.

(9) CAPPI  Number of prediction points per quadrant of the orbit.

(10) OPOUTI Control parameter indicating option to include or exclude frequency distribution of position and velocity errors in printed output.

(11) OPOUT2 Control parameter indicating option to include or exclude punch card output.

(12) ERPDOPT Control parameter indicating whether distributions are desired.

Items other than DPVBLOC are input via the ERPRED Control Card.

The output from ERPDIST routine consists of the following data:

(a) Identification of error quantity

(b) Mean error
(c) Standard deviation of error
(d) Minimum error
(e) Maximum error
(f) Time since epoch in minutes

Additional output data, optional to the ERPDIST routine, includes:

(g) Frequency distribution of errors
(h) Punch cards containing items (a) through (f) above

3.8.2 ERPDIST FORMULATION

The presentation of the computations involved in the ERPDIST Unit is given under Common Subroutine, STOB.

3.8.4 ERPDIST SCHEMATIC COMPUTATIONAL SEQUENCE

   Figure 3-17 presents the flow diagram for the ERPDIST unit.
SECTION 4

EXECUTIVE PROGRAM

The Executive Program (EP) has two main functions to fulfill in the system: the first, is that of processing all input data and converting them to convenient formats for internal use; the second, is that of providing linkage between the component programs in the system. In order to minimize the size and complexity of the SEA Executive Program, SYS (Philco 2000 Operating System) service routines and subroutines were used whenever possible.

4.1 PROGRAM DESIGN

The SEA EP is divided into three main functional units, one of which contains two program units. These three units accomplish the tasks of input processing and internal program linkage as follows:

(1) General Executive Program (EXEC)

EXEC is the main executive unit which does the basic input processing and linkage.

(2) Special Executive Programs (INTERFN and CONTROLN)

The special executive logic necessary to control a sequence number "N" is contained in CONTROLN and INTERFN. CONTROLN contains input tables, program unit table, etc., and INTERFN contains the executive programming that is actually performed as opposed to control cells and tables. This additional executive control is necessary to implement the special logic required for the specific sequence operations.
(3) **Subroutines (SUBS)**

SUBS contains most of the common subroutines used by the SEA program units. SUBS contains card reading routines, retrieval routines, computational subroutines, and other miscellaneous subroutines. A list of all the subroutines is given in the System Subroutine Section.

These four program units (EXEC, CONTROLN, INTERFN, and SUBS) are necessary in all SEA sequences. Therefore, they are loaded along with the specific program units required for each sequence.

### 4.2 DESCRIPTION OF GENERAL EXECUTIVE LOGIC

The flow diagram of the general logic of the Executive Program is presented in Figures 4-1 through 4-4. In order to associate the description of the executive logic with the schematic representation, various points in the flow diagram are designated numerically (n) and are referenced in this manner in the text. After SYS has brought an SEA sequence into core memory, control is transferred to the EP at SEASTRT (1). This routine does all the initialization of the EP, such as clearing switches and indicators, setting up error recoveries, initializing the output routine, and outputing headings. After accomplishing its tasks, SEASTRT transfers control to AAA (the central input processor). AAA retrieves an input card using INXTCON (2) and examines columns 17 to 24 and 80 of each input card to determine its function (3), (4), (5). If it is a legal SEA card, SYS card, or data card, AAA jumps to the correct processing routine or subroutine (6), (7), (8). If the card is not a legal type, AAA rejects the card with a diagnostic comment (9). Most of the card processing routines return to AAA. CONINT is the control card process (18) and always returns to AAA. Routines that do not always return to AAA are SYSRET, JOB, SEACARD and ENDDATA.

A "SYS" card or a "JOB" card will signal SEA to return to SYS. SYSRET and JOB (20), (26) return control to SYS after it has been restored (24), (25). A case ("SEA") card causes the EP to initialize for a case. This is done in SEACARD (11). SEACARD can transfer control to NXJOB if the case card is illegal (17) or to ENDDATA if two case cards are found with no ENDDATA card separating them (16), otherwise, SEACARD returns to AAA (14), (15). An "ENDDATA" card signals SEA to run the case just input. The ENDDATA routine checks the input received against the required input to run (Boxes 12 and 13). ENDDATA never returns to AAA. If the case had any serious input errors, ENDDATA will transfer control to
SAVE CONTENTS OF THE SYS ENTRY VECTORS FOR CONTROL-LINE-ERROR PROCESSING, SYS INITIALIZATION, AND END OF JOB PROCESSING. SET THE ENTRY VECTORS TO SAVE THE JA IN ENTRYJA AND TRANSFER CONTROL TO SYSCONR, SYSINT AND SYSSJOBS RESPECTIVELY.

INITIALIZE THE OUTPUT ROUTINE (PANT) TO OUTPUT ONTO TAPE 5. EJECT A PAGE ON HARD COPY OUTPUT.

SET THE SYS MASTER CONTROL SWITCH, CONBITS, TO INHIBIT CONTROL CARD PROCESSING BY 1NXTCON.

SET CELLS 0 AND 3 TO RETURN TO SEAERR IN THE CASE OF EXPONENT OVERFLOW OR SUBROUTINE ERROR.

READ THE ACCOUNTING CLOCK AND STORE THE DATE AND TIME IN OUTPUT LINE. OUTPUT THE LINE AS COSINE5B PAGE HEADING. TYPE "COSINE5B" AND THE SEA NUMBER ON THE FLEXOWRITER.

INITIALIZE TABLE LOOKUP ON DATA CARDS AND CONTROL CARDS.

SET THE SEA ID AND CASE ID = BLANKS.

FIGURE
Figure 4-4. Executive Program (Continued)
JOBSRCH (19) initiating a search for the next case or job. If the case did not have serious input errors, ENDDATA will exit to EXEND (10) and initiate the running of the case. "PRINT" and "FLOAT" cards will execute the PRINT or FLOAT subroutines described in the System Subroutine Specifications.

The central routine used in sequence control is EXEND (30). EXEND increments the program number (PROGNO) and transfers control to the next program in sequence, using PROGTBL. Normally, programs return to EXEND; however, if a nonrecoverable error occurs during a case run, the program unit puts out a diagnostic comment and exits to NXJOB (27). After putting out a comment indicating that the case was terminated, NXJOB transfers control to JOBSRCH (28).

Normal termination of a case is executed by a jump to SEAEOJ (29). This routine is the last entry in PROGTBL and the EXEND logic will result in a transfer of control to SEAEOJ after completion of the last program unit. SEAEOJ puts out a comment indicating that the case has ended and transfers control to JOBSRCH.

JOBSRCH (28) searches the input until a SYS, JOB, or case card is found, in which case it transfers control to SYSRET (20), JOB (26), or AAA (2), respectively.

The SEA system will retain control until a SYS or JOB card is intercepted, or until the operator executes a jump to cell 1, 4, or 5 from the console in an attempt to initialize SYS or run the next job. In any of these conditions, the EP will restore the SYS entry vectors, reset the SYS master control switch CONBITS, and exit to the right half of cell 1 (23), 4 (24), or 5 (25). The exit taken depends on the next SYS function desired.

4.3 DESCRIPTION OF SPECIAL EXECUTIVE LOGIC

Situations arise in any system that require special logic and handling. Rather than incorporate these in a general EP, the SEA system isolates these "special executive" routines in the program unit INTERFN. These perform the logic needed during a case run to accomplish special tasks required, such as performing a Monte Carlo-Differential Correction loop. These are written as small sequence programs and have entries in PROGTBL. They therefore return to EXEND. At present, the special executive routines in the SEA system and their functions are as follows:

EXEC1AA Outputs nominal elements. Restricts sensor data to one sensor in Type C and D elements. EXEC1AA is the first entry in PROGTBL.
EXEC1B Initializes Differential Correction and Monte Carlo. Initializes MOCARO - SGPDC loop. EXEC1B is between OBSIM and MOCARO in the PROGTBL.

EXEC1C Increments counter of MOCARO - SGPDC loops (KCOUNT) and compares it to the number of runs requested on the case input (K). If more loops are required, EXEC1C decrements PROGNO by 3 and exits to EXEND. If not, EXEC1C outputs the final random number and number of unsuccessful corrections and then exits to EXEND without altering PROGNO. EXEC1C is between SGPDC and DCDIST in the PROGTBL.

4.4 DESCRIPTION OF EXECUTIVE Routines AND SUBROUTINES

EXEND Normal end of program return.

(EXEC) If a sequence program is executed in a normal fashion, i.e., no fatal errors detected, the program returns to EXEND signalling the EP to transfer control to the next program in sequence. EXEND increments the left address of PROGNO by 1 and adds it to the address of PROGTBL-l. This is the location of a jump to the next program in the sequence.

NXJOB or Error end of sequence exit.

EXEND Normal end of program return.

(NEXTJOB) If a sequence program encounters a fatal error when attempting to run a case, control is returned to NXJOB, following a diagnostic comment. NXJOB indicates that the case is terminated both on the flexo and on hard copy. It then transfers control to JOBSRCH to begin the next case.

JOBSRCH Job or case search entrance.

(EXEC) JOBSRCH processes the input data on Tape 8, searching for one of the following three cards:

Col 17-24 = SEA - case card
      = SYS - SYS card
      = JOB - JOB card

4-8
If a case card is found, JOBSRCH repositions the input to the case card, resets cells 0 and 3 for the EP error processing, and transfers control to AAA. If a SYS card is found, JOBSRCH transfers control to SYSRET. If a JOB card is found, JOBSRCH transfers control to JOB.

**JOB**

JOB card processing.

**(EXEC)**

JOB types a comment on the flexo indicating that a JOB card was intercepted, repositions the input retrieval to the JOB card and exits to SYSJOB.

**SYSJOB**

SYS job processing.

**(EXEC)**

SYSJOB resets CONBITS, empties the output buffers in PANT, restores the SYS entry vectors, and exits to M/4 right.

**SYSRET**

Return control to SYS

**(EXEC)**

SYSRET resets CONBITS, empties the output buffers in PANT, restores the SYS entry vectors, and exits to M/5 right.

**SYSINT**

Initialize SYS

**(EXEC)**

SYSINT resets CONBITS, empties the output buffers in PANT, restores the SYS entry vectors, and exits to M/1 right.

**SEASTRT**

Initialization of SEA exec.

**(EXEC)**

SEASTRT does all the initialization required of the SEA executive routine. It saves the contents of the SYS entry vectors ISYSIN, IENJOB, and XCONER and changes them to set the ENTRYJA and transfer control to SYSINT, SYSJOB and SEACONR, respectively; initializes PANT to output onto Tape 5, ejects a page, and outputs COSINE 5B headings with the date and time; sets CONBITS for SEA usage; sets cells 0 and 3 to return to SEAERR; sets the size of the data card table and control line ID table = 0 (to prevent table lookup from matching until after a case card); blanks the SEA and case ID's; and then exits to AAA.

4-9
Control line error processing.

EXEC If an error occurs on SYS control lines, SEACONR prints an error comment on hard copy, and types an error comment if input is from the flexo. In either case, control is returned to AAA.

SEAERR Exponent overflow or subroutine error processing.

EXEC SEAERR outputs an error comment and then transfers control to NXJOB.

AAA Central Executive input processor

EXEC AAA uses INXTCON to retrieve the next input card, and uses STRIP to extract the command field (Col 17-24). AAA uses table A1A to determine if the card is an SEA card. If equality is found with one of the SEA card functions, AAA jumps to the corresponding entry in table A1B to convert the card. Subroutines that process SEA cards are SEACARD (Case card), ENDDATA (Enddata card), PRINT (Print card), FLOAT (Float card), CONINT (Control card), JOB (Job card), and SYSRET (SYS card). Subroutines PRINT, FLOAT, and CONINT will return to AAA; JOB and SYSRET restore SYS and return control to SYS; SEACARD normally returns control to AAA, however can go to ENDDATA or NXJOB; and ENDDATA always returns control to EXEND or JOBSRCH.

If the card is not an SEA card, then AAA uses TABLE1 to determine if the card is a legal SYS card. If it is, control is transferred to BLKIN with a parameter of 8 (Block 8 of the SYS Tape desired). BLKIN will locate Block 8 which will trigger the SYS card processing. After the card has been processed, SYS will return to INXTCON which will retrieve the next card, and return to ARET (in AAA). If the input card is not an SEA or SYS card, AAA checks to see if a Case card has been found. If not, data cards are not yet allowed, and the card will be rejected with a diagnostic comment. If a Case card has been found, AAA will compare Col 80 of the input card to legal data card types as given in the table specified in CARDTBL left address. If equality is found, AAA
jumps to the corresponding entry in the table specified in CARDTBL right address, which is a subroutine to process the particular data card. After the card has been processed, control is returned to AAA. If the input card is none of the above legal inputs, it is rejected with a comment indicating that an error exists in Col 17-24 or 80. Control is then returned to AAA.

SEACARD

Case Card Processor

EXEC

SEACARD processes a Case card (SEA in Col 17-24). It checks the SEA number against the sequence number held internally and sets up the SEA ID and Case ID on the page headings. It also clears all switches and indicators, and initializes the input processing including table lookups on data cards and control card ID's. SEACARD normally exits to AAA, however, with various error conditions, it can exit to ENDDATA (previous Case card encountered with no ENDDATA card on case), or NXJOB (SEA ID disagreement).

ENDDATA

ENDDATA Card Processor

EXEC

ENDDATA processes an ENDDATA card. This primarily consists of checking the data successfully processed in the case and comparing it to the minimal data requirements for the sequence being run. ENDDATA outputs error diagnostics indicating which types of data cards were not found and which types of control cards were not found. Deficiencies in either type of card will cause ENDDATA to inhibit the running of the case. If all data required was found, ENDDATA checks the no-run switch (bit0-EXSWTCH) for an inhibit set during the input processing. If no run is set, ENDDATA will not run the case, but transfers control to JOBSRCH. If no errors were found and the case is to be run, ENDDATA transfers control to EXEND.

CONINT

Control Card Processor

EXEC

CONINT processes CONTROL (CONTROL in Col 17-24) cards. Using the table of N entries (N specified by CONPRO right address) beginning at a location TABLE (specified by CONPRO left address), CONINT does a table
lookup on the CONTROL card, ID given in Col 9-16. If equality is found, CONINT jumps to N plus the core location in TABLE equal to the ID. This must be a jump to a subroutine to process the CONTROL card, and a jump to AAA. CONINT therefore returns control to AAA.

The subroutines used by CONINT must set a bit in cell CCARD after a successful card read is executed. This signals ENDDATA that the specific control card was found and read without any errors. For bit assignments, see cell CCARD.

**SEAEOJ** Sequence Termination

**(EXEC)** SEAEOJ terminates an SEA sequence. After printing and typing "END OF CASE" SEAEOJ empties the output buffers and exits to JOBSRCH for the next case.

**INPTINT** Initialization Subroutine

**(INTERFN)** When the EXEC encounters a Case card, it will go to the subroutine INPTINT. This should do all necessary initialization of the input routines for the sequence, such as setting up strobes and clearing counters for various data blocks (i.e., EBLOC, OBLOC, etc.).

### 4.5 DESCRIPTION OF EXECUTIVE CONTROL SWITCHES AND TABLES

**EXSWTCH**

<td>Control cards required. A bit is set = 1 for each type of control card required to run the sequence. Bit assignments must be the same as those for CCARD.</td>
</tr>
<tr>
<td>CONPROZ</td>
<td>C/HLT; C/HLT, TABLE where location TABLE must contain the following:</td>
</tr>
</tbody>
</table>
| (CONTROLN) | TABLE W/AQTINT  
W/MOCARO  
W/SGPDC, etc. |
| CONPRO | C/HLT, TABLE1; D/HLT, N where location |
| (CONTROLN) | TABLE1 must contain the following: |
| | TABLE1 W/00AQTINT  
W/00MOCARO  
W/00SGPDC etc. |
| | The BCD words given correspond to the ID's expected on the control cards required as specified by CCRDOPT. The first entry in TABLE1 will correspond to the first bit (counting from the left) in CCRDOPT. The number of entries in TABLE1 will be the same as the number of bits set in CCRDOPT. Each entry should be centered, if possible, within the 8 characters of the word, with unused characters left blank. |
| | The BCD words given correspond to the ID's on the control cards required. The ID's must be right adjusted with leading zeros. N = the number of entries in TABLE1. TABLE1 must be followed by a TABLE2 where TABLE2 contains the following: |
| | TABLE2 C/JMP, AQTC; C/JMP, AAA  
C/JMP, MC; C/JMP, AAA  
C/JMP, DCON; C/JMP, AAA etc. |
| | "AQTC" is a subroutine to convert the control card with the ID "AQTINT"; "MC" is a subroutine to convert the control card with the ID "MOCARO", etc. The first entry in TABLE2 must correspond to the first entry in TABLE1. TABLE2 will be N entries long and must be located immediately after TABLE1 (or at location TABLE1 + N). |
| CARDTBL | C/HLT, TABLE1; C/HLT, N where location 4-14 |
TABLE1 must contain the following:

TABLE1  W/0000000A
         W/0000000B
         W/0000000C  etc.

The BCD character given corresponds to the card types in Column 80 of the data cards required by the sequence. The card types must be right adjusted with preceding zeros.

N = the number of entries in TABLE1.

TABLE1 must be immediately followed by TABLE2 (TABLE2 start address = TABLE1 start address + N). TABLE2 contains the following:

TABLE2  C/JMP, ACARD; C/JMP, AAA
         C/JMP, BCARD; C/JMP, AAA
         C/JMP, CCARD; C/JMP, AAA  etc.

"ACARD" is a subroutine to convert the data card with "A" in Col 80; "BCARD" is a subroutine to convert the data card with "B" in Col 80, etc. The first entry in TABLE2 must indicate a subroutine which converts the data card indicated by the first entry in TABLE1. TABLE2 will be N entries in length.

**PROGTBL**  Program jump table

**PROGTBL**  C/JMP, PROG1
          C/JMP, PROG2
          ...
          C/JMP, PROGN
          C/JMP, SEAEOJ

PROG1 is the starting instruction of the first program in the sequence; "PROG2" is the starting instruction of the second program in the sequence, etc.; and "PROGN" is the starting instruction of the last program in the sequence. This will control the running of programs, as the EXEC will transfer control to the programs sequentially. A jump to SEAEOJ must always be the last entry in the table. Each program above should exit to "EXEND" or "NXJOB" in the case of an error.
PROGNO C/HLT, N, C/HLT, where N is the number of the program currently being run. The "Jump and Address" used to transfer control to the program N is at location PROGTBL - 1 + N. PROGNO is incremented by EXEND.

CONBITS SYS master control word, used by SYS for all switches, inhibits, flags, etc. The exact bit assignments are as follows:

bit 0 Always = 0, not used
bit 1-15 Address of next input card to be processed. Used only if input is from magnetic tape. The address is between 6008 and 7708. If the address equals 7708, the next input card is in the next block on Tape 8.
bits 16-20 Not used
bit 21 = 1 if SYS is to search for a "JOB" card, bypassing all other control cards. This search will occur at the next entry to INXTCON (M/5).
= 0 if SYS is to retrieve the next sequential control line at the next entry to INXTCON.
bit 22 = 1 if input on Tape 8 is in the image mode.
= 0 if input on Tape 8 is in the code mode.
Not used if input is not from magnetic tape.
bit 23 = 1 indicates that the information in the input buffer (M/600 - M/777) has been destroyed, and SYS must reread the last block of data from Tape 8 when the next control line is requested in INXTCON.
= 0 if the information in the input buffer has not been destroyed.
Not used if input is not from magnetic tape.
bit 24 Always = 0, not used.
bits 25-39 Left shift required of "PTWORD" to bring the next character to be processed T5 (in bits 0 to 5). If the number = 48, PTWORD has been entirely processed and the next character is in the next word of the control line.
bit 40  Always = 0, not used.
bit 41  = 1 if the accounting clock is in the system (part of the computer complex).
       = 0 if no accounting clock is available.
bit 42  = 1 if the next control line is not to be processed immediately upon retrieval.
       "INXTCON" will move the next control line into "CONLINE" without processing it, and exit to the "ENTRY JA."
       = 0 if the next control line is to be processed immediately after it is retrieved.
bit 43  = 1 if image mode input from magnetic tape should be converted to code mode from Col 1 to Col 24, leaving Col 25 to Col 80 in image mode.
       = 0 if image mode input from magnetic tape should be converted to code mode from Col 1 to Col 80. Not used if input is not image mode from magnetic tape.
bit 44  = 1 if a "JOB" card is not legal at this time (e.g. - during compilation).
       = 0 if a "JOB" card is allowed.
bit 45  = 1 if input is from magnetic tape.
bit 46  = 1 if input is from paper tape.
bit 47  = 1 if input is from the flexowriter.

One and only one of the bits 45 to 47 must be set = 1, the other two must be = 0.
SECTION 5

SYSTEM SUBROUTINES

The subroutines available to the Simulation Error Analysis System are classified in four groups: Program, SYS, Philco, and Common. Philco subroutines are accessible from the Philco Subroutine library tape and are read into core by SYS as required. SYS subroutines are in the area of core allocated to SYS; therefore, they are available as long as SYS is retained in core. Program subroutines are those used by one specific program and are compiled with it. In order to conserve core space, the subroutines used by more than one program have been collected into a section called SUBS and are designated the Common System Subroutines.

This section presents the input, output, and calling sequences for all of the common subroutines and a few of the frequently used SYS subroutines. Philco subroutine specifications are a part of the Philco documentation which may be obtained from the Philco Computer Division. The subroutines are presented in alphabetical order and are dated for anticipated revisions and additions.

Input and output quantities will have an associated symbol, when applicable, designating the format of the word. The formats are assigned as follows:

D - Decimal
F - Floating Point
O - Octal
BCD - Binary Coded Decimal
Tx - Fixed Point Number with x as the scale factor

Within the calling sequences, many capitalized words are in parentheses to indicate that they are not absolute core locations. These locations must be assigned by the user when calling one of the subroutines.
The subroutines exit to core cells 0 (exponent overflow) or 3 (standard error) bypassing the normal exit when encountering non-recoverable errors. Programs using these routines must preset cells 0 and 3 for error recovery procedure.
PURPOSE: To read the Accounting Clock and convert it to standard (6-Bit) BCD format.

CALL SEQUENCE: JMP AKLOK
TAM (RESULT 1)
TQM (RESULT 2)

INPUTS: None

OUTPUTS: RESULT 1 = Δ Δ Δ Y Y M M
RESULT 2 = D D H H M M . M

STORAGE REQUIREMENTS: 11 Cells

SUBROUTINES: Common: KLOK

DESCRIPTION:

Since the Accounting Clock does not contain the year, the last two digits of the year in core location ZYEAR are inserted in bits 24-35 of Result 1, after the Accounting Clock has been converted from 4-bit BCD to 6-bit BCD.

Note: ZYEAR must be updated yearly.
PURPOSE: To convert an AQTINT Control Card.

CALL SEQUENCE:
JMP AQTCON
JAZ (ERROR)

INPUTS:
AQTINT Control Card
CCARD - See Description

OUTPUTS:
OBSDUR = Observation duration (minutes) (F)
TOPT = Output option for TBLOC D(T 47)
OBSOPT = Output option for OBSIM D(T 47)
PERT = Perturbations control (for all programs except DC) D(T 47)
PNCHOB = Punched output option for OBSIM D(T 47)
CCARD = See Description

STORAGE REQUIREMENTS: 33 Cells

SUBROUTINES: Common: SFXFLTA, SFXINT, CARDER, PANT

DESCRIPTION:
Core location CCARD is checked to see that an AQTINT Control Card has not been converted for the case. If one has been processed, the current one will be rejected with an error comment and the A Reg = 0; if not, the card will be converted, and Bit 1 will be set = 1 in CCARD to indicate a successful conversion. If an error occurs during conversion, an error comment will be printed and the subroutine will exit with the A Reg = 0.
PURPOSE: To find the arc cos of a floating point number

CALL SEQUENCE: TMA (WORD)
               JMP ARCCOS
               JMP (ERROR)
               TAM (RESULT)

INPUTS: WORD = Cos (X) (Floating point)

OUTPUTS: RESULT = X, 0 ≤ X ≤ π (Floating point)

STORAGE REQUIREMENTS: 14 Cells

SUBROUTINES: Philco: FACOS

DESCRIPTION:

Due to cumulative computational round-off errors, it is possible for the cosine of an angle near 0° to be greater than 1. Therefore a comparison is made between cos (X) and 1.001:

\[
\text{if } \cos (X) \quad \text{is} \quad \begin{cases} 
> 1.001 \rightarrow \text{ERROR} \\
\geq 1.0 \text{ and } < 1.001 \rightarrow X = 0 \text{ or } \pi \\
< 1.0 \rightarrow 0 < X < \pi
\end{cases}
\]
PURPOSE: To find the arc sin of a floating point number

CALL SEQUENCE: 
MA (WORD)
JMP ARCSIN
JMP (ERROR)
TAM (RESULT)

INPUTS: WORD = Sin (X) (Floating point)

OUTPUTS: Result = X, \( \pi/2 \leq X \leq \pi/2 \) (Floating point)

STORAGE REQUIREMENTS: 16 Cells

SUBROUTINES: Philco: FASIN

DESCRIPTION:

Due to cumulative computational round-off errors, it is possible for the sine of an angle near 90° to be greater than 1. Therefore a comparison is made between sin (X) and 1.001:

\[
\text{if } |\sin (X)| \text{ is } \begin{cases} 
> 1.001 \rightarrow \text{ERROR} \\
\geq 1.0 \text{ and } \leq 1.001 \rightarrow X = \pm \pi/2 \\
< 1.0 \rightarrow -\pi/2 \leq X < \pi/2
\end{cases}
\]
PURPOSE: To find the arc tan of a floating point number

CALL SEQUENCE: TMA (WORD 1)  
                TMQ (WORD 2)  
                JMP ARCTAN  
                TAM (RESULT)

INPUTS: WORD 1 = Cos (X)  
         WORD 2 = Sin (X)  

OUTPUTS: RESULT = X, 0 ≤ X ≤ 2π (Floating point)

STORAGE REQUIREMENTS: 17 Cells

SUBROUTINES: Philco: FATAN

DESCRIPTION:

If sin (X) = 0 and cos (X) = 0, then X = 0 arbitrarily with no error indication.
PURPOSE: To read the Accounting Clock and edit it for printing or typing.

CALL SEQUENCE: JMP BCDCLK
              TAM (RESULT 1)
              TQM (RESULT 2)

INPUTS: None

OUTPUTS: RESULT 1 = YY - MM - DD
          RESULT 2 = HH - MM.M

6-Bit BCD

STORAGE REQUIREMENTS: 29 Cells

SUBROUTINES: Common: AKLOK

DESCRIPTION:

This subroutine uses AKLOK to get the Accounting Clock and year in 6-Bit BCD, putting it in the format for printing and typing.
PURPOSE: To convert BCD date to floating point days and fractions since the beginning of the year

CALL SEQUENCE:

TMA (WORD 1)
TMQ (WORD 2)
JMP BCDFD
JAZ (ERROR)
TAM (RESULT 1)
TQM (RESULT 2)

INPUTS:
WORD 1 = YMMDDHH 6-Bit BCD
WORD 2 = MMSS.SSS

OUTPUTS:
RESULT 1 = Integral number of days
RESULT 2 = Fractional number of days

STORAGE REQUIREMENTS 71 Cells

SUBROUTINES: Common: SFXFLTA

DESCRIPTION:

If an error is found, the normal exit will be taken with the A Reg = 0
PURPOSE: To set input card retrieval (INXTCON) to reprocess last control line.

CALL SEQUENCE: JMP BCK1CRD

INPUTS: Left address of CONBITS = Location of current control line.

OUTPUTS: Left address of CONBITS = Location of previous control line.

STORAGE REQUIREMENTS: 20 cells

SUBROUTINES: Common: PANT
SYS: 1TYPOUT

DESCRIPTION:

If input is from magnetic tape, the cell CONBITS is reset to location of previous card image. If input is from the flexowriter, the comment "IMPROPER CONTROL LINE" is typed. If input is from paper tape, the comment "CONTROL LINE ON PAPER TAPE OUT OF ORDER" is printed.
PURPOSE: To call in the block of the SYS Tape specified and transfer control to it.

CALL SEQUENCE:  
C/JMP, BLKIN; N/7T47  
Control returned to ENTRYJA  
ENTRYJA not set by JMP BLKIN

INPUTS:  
# = The decimal number of the block desired  
Example: C/JMP, BLKIN; N/7T47 to retrieve the seventh block on tape 1 (SYS tape)

OUTPUTS:  
Execution of program in block # given

STORAGE REQUIREMENTS:  
Part of SYS

SUBROUTINES:  
SYS subs only

DESCRIPTION:  
BLKIN reads the SYS tape into cells M/400 to M/577 searching for the block number specified. When block # is found, BLKIN jumps to M/401, and thereby transfers control to the routine in the block specified. Normally control will be returned to the ENTRYJA, thus back to the entry to SYS just prior to the jump to BLKIN.
PURPOSE: To output card error comments.

CALL SEQUENCE: (1) TMA (WORD) JMP CARDER
(2) TMA (WORD1) JMP CARDERA
(3) JMP CARDERB
(4) TMA (WORD2) JMP CARDERC

INPUTS: In all cases, XR3 must contain the location of the erroneous card:

WORD = ?? ?? ?? ?? ?? ?? NN (BCD Column Number)
WORD1 = ?? ?? ?? ?? ?? ?N (BCD Card Type)
WORD2 = ?? ?? ?? ?? ?? ?N (BCD Card Type)

OUTPUTS: See Description

STORAGE REQUIREMENTS: 48 Cells

SUBROUTINES: Common: PANT, PAGECON

DESCRIPTION:
The subroutine will insert the given parameter into one of the following comments corresponding to the entrance:

(1) - Error in field ending in Col. NN.
(2) - System expects card with N in Col. 80.
(3) - (No comment)
(4) - Card rejected, too many cards of type N.

The program will then output the comment (or no comment) followed by:

1 8 16 24 32 40 48 56 64 72 80
(80 Column Card Image)
1 Line space

CARDER subroutines set the no-run switch for the EXEC (bit 0 of EXSWITCH), except for the CARDERC routine.
PURPOSE: To issue a carriage return to the flexowriter.

CALL SEQUENCE: JMP CARRET

INPUTS: None

OUTPUTS: A carriage return character transmitted to the flexowriter

STORAGE REQUIREMENTS: 2 cells

SUBROUTINES: None
PURPOSE: To retrieve one contaminated observation from COBLOC

CALL SEQUENCE:
1. To initialize:
   JMP INITCOB
2. Normal:
   JMP COBGET
   +1H JMP (END)
   +2H (NORMAL)

INPUTS:
- COBLOC
- LOCCOB = C/HLT, COBLOC; C/HLT, 0
- Termination indicator for COBLOC must be 48/0

OUTPUTS:
- END = End of contaminated observations
- NORMAL = A REG = STAID

STORAGE REQUIREMENTS: 8 Cells

SUBROUTINES: None

DESCRIPTION:
It is necessary to "JMP INITCOB" only before the first "JMP COBGET." INITCOB sets the beginning address of COBLOC; with every call of COBGET, this address is modified to retrieve the next successive contaminated observation. The maximum number of contaminated observations is 500.
PURPOSE: To pack one contaminated observation into COBLOC

CALL SEQUENCE: (1) To initialize: (2) Normal:

JMP ICOBPCK
JMP COBPCK

INPUTS: LCOBLOC = C/HLT, COBLOC; C/HLT, COBLOC + 3000

STAI D
OTYPE
RANGE
ALPHA
DELTA
RODOT

(See COBLOC format for contents of core locations)

OUTPUTS: One contaminated observation in COBLOC (See COBLOC format)

STORAGE REQUIREMENTS: 46 Cells

SUBROUTINES: Common: PANT, GLOP, PAGECON
Program: OBPKA, OBPKS (See OBPK)

DESCRIPTION:

It is necessary to "JMP ICOBPCK" only before the first "JMP COBPCK". ICOBPCK sets the beginning address of COBLOC. With every call of COBPCK this address is modified in order to pack the next observation successively. 500 observations may be stored in COBLOC; observations in excess of 500 will be printed.
PURPOSE: To convert a SGPDC Control Card.

CALL SEQUENCE: JMP DCCON JAZ (ERROR)

INPUTS: SGPDC Control Card CCARD

OUTPUTS:

- DCCCPI - Correction flag override (0, bits 41 through 47 only)
- DCCCNP2 - Repeat counter override (BCD)
- DCCCNP3 - Perturbations Control (DC) (D/T47)
- DCCCNP4 - Output Options (0, bits 42 through 47 only)
- DCCCNP5 - RMS multiplier override (BCD)
- DCCCNP6 - First absolute maximum override (F)
- DCCCNP7 - Second absolute maximum override (F)
- DCCCNP8 - ABSMX2 override (F)
- DCCCNP9 - Convergence criterion override (F)
- DCCCNP10 - DC distribution override (D/T47)

- DCSI - Lower limit (distribution) (F)
- DCNS2 - Upper limit (distribution) (F)
- DCNS - No. of quantities to compute range of distribution (D/T47)
- DCI - No. of cells in distribution (D/T47)
- CCARD - See Description

STORAGE REQUIREMENTS: 61 Cells

SUBROUTINES: Common: SXSRCH, CARDER, PANT

DESCRIPTION:

Core location CCARD is checked to see that a DC Control Card has not been converted for the case. If one has been processed, the current one will be rejected with an error comment and the A Reg = 0; if not, the card will be converted. If S1 and/or S2 = 0, then S1 and/or S2 will be set = 3. The subroutine will then make the following tests:

1. S1 and S2 = 0
2. S1 or S2 Neg
3. I Neg
4. I ≥ 101

If any of the above are true, or if there was an error on conversion, the card will be rejected with an error comment and the A Reg = 0. If the card conversion is successful, Bit 3 will be set = 1 in core location CCARD.
PURPOSE: To retrieve a delta element set from DEBLOC

CALL SEQUENCE: (1) To initialize
   JMP INITDEL
   +1H JMP DELGET
   +2H JMP (END)
(2) Normal:
   JMP DELGET
   (END)

INPUTS: LOCDEL = C/HLT, DEBLOC; C/HLT, 0
   Termination indicator for DEBLOC must be 48/0

OUTPUTS: END = End of DEBLOC
   DELA
   DELE
   DELO
   DELNOD
   DELOM
   DELMO
   DELCO
   (See DEBLOC format for contents of core location)

STORAGE REQUIREMENTS: 17 Cells

SUBROUTINES: None

DESCRIPTION:

It is necessary to "JMP INITDEL" only before the first "JMP DELGET". INITDEL sets the beginning address of DEBLOC. With every call of DELGET this address is modified to retrieve the next successive set of delta elements. The maximum number of sets of delta elements is 100.
PURPOSE: To pack one delta element set into DEBLOC

CALL SEQUENCE: (1) To initialize
                JMP IDELPCK
                (2) Normal
                JMP DELPCK

INPUTS: LDEBLOC = C/HLT, DEBLOC; C/HLT, DEBLOC + 700
        \{DELA
        DELE
        DELI
        DELNOD
        DELOM
        DELMO
        DELCO\}
            (See DEBLOC format for contents of core locations)

OUTPUTS: One set of delta elements in DEBLOC (See DEBLOC format)

STORAGE REQUIREMENTS: 41 Cells

SUBROUTINES: Common: PANT, GLOP, PAGECON

DESCRIPTION:

It is necessary to "JMP IDELPCK" only before the first "JMP DELPCK". IDELPCK sets the beginning address of DEBLOC. With every call of "DELPCK" this address is modified in order to pack the next delta element set successively. 100 sets of delta elements may be stored in DEBLOC. The delta element sets in excess of 100 will be printed.
PURPOSE: To control the conversion of nominal and variant element cards 1 and 2 into EBLOC and VEBLOC format.

CALL SEQUENCE: (1) To initialize
JMP ECARDI

(2) Normal
JMP ECARD

INPUTS:
XR3 = Location of card image
For E Card processing, the following locations must be set initially:

LEBLOC = C/HLT, EBLOC; C/HLT, EBLOC + 12
SATSTB = C/HLT, EBLOC; C/HLT, 0

For V Card processing, the following locations must be set initially:

LVEBLOC = C/HLT, VEBLOC; C/HLT, VEBLOC + 700
ELMSTB = C/HLT, VEBLOC; C/HLT, 0
LDEBLOC = C/HLT, DEBLOC; C/HLT, DEBLOC + 700
DELSSTB = C/HLT, DEBLOC; C/HLT, 0

OUTPUTS:
See Output of VECARD or ELMRED

For E Card processing:

Increments left address of SATSTB by 12
Increments ECOUNT by 1
Sets right address of LOCSAT equal to left address of SATSTB
Sets Bit 1 = 1 in core location CARDS

For V Card processing:

Increments left address of ELMSTB and DELSTB by 7
Increments VECOUNT and DECOUNT by 1
Sets right address of LOCELM and LOCDEL equal to the left address of ELMSTB and DELSTB respectively
Sets Bit 5 = 1 in core location CARDS
SIMULATION ERROR ANALYSIS SYSTEM

STORAGE
REQUIREMENTS: 184 Cells

SUBROUTINES: Common: CARDER, PANT, PAGECON, ELMRED, VECARD

DESCRIPTION:

Nominal element cards must be input before variant element cards.

It is necessary to "JMP ECARDI" only before the first "JMP ECARD" to initially clear buffers. A pair of element cards (cards 1 and 2) must be entered together; if not, the subroutine will search for a pair, while saving the most recent cards in a buffer and printing error comments on those rejected. Having found a pair of element cards, a comparison is made as to whether both cards have the same element type (A, B, C, or D), satellite number, and card type (E or V). If all 3 do not agree, the search for a pair is begun again, while the most recent cards are saved and an error comment is printed. If all 3 agree, card type is tested to determine which routine should unpack the cards: E = ELMRED (nominal element cards) or V = VECARD (variant element cards). If the cards converted were variant element cards, the subroutine will fill DEBLOC with nominal classical elements to be used later to create a true delta element block. Having successfully converted the cards, the subroutine will set counters, strobes and CARDS, then exit. If unsuccessful, the program will take the normal exit, but the appropriate card bit will not be set in core location CARDS.
PURPOSE: To unpack Element Card 1.

CALL SEQUENCE: TMA (WORD)  
               JMP  ELEM1

INPUTS: WORD = C/HLT, (Elem. Card 1 address); C/HLT, (Output buffer address)  
        Element Card 1

OUTPUTS: Output buffer-formats for element types A, B, C, D, respectively. In the first word, N = satellite number. All numbers are floating point except those designated as BCD.

</tbody>
</table>

Z = NORTH  P = NS  (BCD)

STORAGE REQUIREMENTS: 24 Cells

SUBROUTINES: Common: SFXFLT

DESCRIPTION:

The subroutine unpacks element card 1 and stores the input numbers into the output buffer as shown above. If an error is found in converting the numbers to floating point, the normal exit will not be taken. Rather, the subroutine will transfer to core location ELERR1, where error recovery must be set up.
PURPOSE: To unpack Element Card 2.

CALL SEQUENCE: TMA (WORD)
               JMP ELEM2

INPUTS: WORD = C/HLT, (Elem. Card 2 address); C/HLT (Output buffer address)
        Element Card 2

OUTPUTS: The output buffer formats for the various element types are as follows (the BCD character T is filled by the element type A, B, C, or D, AAA is the element number, NNN is the satellite number, and SSS is the sensor number):

Types A or B:
+0 ETAAANNN (BCD)
+1
+2
+3 (To be filled)
+4
+5
+6
+7 $C_0$ (Days/rev) (F)
+8 $t$ (minutes) (F)
+9 (to be filled)
+10 YMMDDHH (BCD)
+11 MISO.SSS (BCD)
REFYEAR 00000000Y
RH00 00000000
ELMSEN 000000X

Types C or D:
+0 ETAAANNN (BCD)
+1
+2
+3 (To be filled)
+4
+5
+6
+7 $C_0$ (Days/rev) (F)
+8 $t$ (minutes) (F)
+9 (to be filled)
+10 $\omega_0$ (Field 1) (BCD)
+11 $\rho_0$ (Field 2) (BCD)
RH00 00000000 or $\rho_0$ (BCD)

STORAGE REQUIREMENTS: 37 Cells

SUBROUTINES: Common: BCDFD, SFXFLT

DESCRIPTION:

The subroutine unpacks element card 2 into the output buffer and core locations as shown above. If errors occur, the normal exit is not taken; rather, the exits indicated will be taken. It is necessary to set up error recovery at these core locations:

Invalid epoch time (field 1) $\rightarrow$ ELERR2
Invalid $C_0$ (field 2) $\rightarrow$ ELERR2A
Invalid $\rho_0$ (field 4) $\rightarrow$ ELERR2B
PURPOSE: To retrieve one variant element set from VEBLOC

CALL SEQUENCE: (1) To initialize:
                   JMP INITELM
(2) Normal:
                   JMP ELMGET
                   +1H JMP (END)
                   +2H (NORMAL)

INPUTS: VEBLOC
        LOCIML = C/HLT, VEBLOC; C/HLT, 0
        Termination indicator for VEBLOC must be 48/0

OUTPUTS: END = End of VEBLOC

AXNO
AYNO
HXO
HYO
H2O
XLO
CO

(See VEBLOC format for contents of core locations)

STORAGE REQUIREMENTS: 8 Cells

SUBROUTINES: Program: NXSAT (See EUNPCK)

DESCRIPTION:

It is necessary to "JMP INITELM" only before the first "JMP ELMGET". INITELM sets the beginning address of VEBLOC. With every call of ELMGET, this address is modified to retrieve a successive variant element set. The maximum number of sets of variant elements is 100.
PURPOSE: To print elements - Type A, B, C, or D

CALL SEQUENCE: JMP ELMOUT

INPUTS: ELMTP = 000000N, N = A, B, C, or D (BCD)
EBUF (Output Buffer)

OUTPUTS: Contents of EBUF

STORAGE REQUIREMENTS: 149 Cells

SUBROUTINES: Common: GLOP, PAGECON, PANT
Program: ELOUTA, ELOUTB, ELOUTC, ELOUTD

DESCRIPTION:

This subroutine tests ELMTP to determine which of the following program subroutines to use to output the values in EBUF:

- Element Type A - ELOUTA
- Element Type B - ELOUTB
- Element Type C - ELOUTC
- Element Type D - ELOUTD

</table>
PURPOSE: To pack one variant element set into VEBLOC

CALL SEQUENCE: (1) To initialize
(2) Normal:
JMP IELMPCK
JMP ELMPCK

INPUTS: LVEBLOC = C/HLT, VEBLOC; C/HLT, VEBLOC + 700
AXNO
AYNO
HXO
HYO
HZO
XLO
CO
(See VEBLOC format for contents of core locations)

OUTPUTS: One set of variant elements in VEBLOC (See VEBLOC format)

STORAGE REQUIREMENTS: 39 Cells

SUBROUTINES: Common: GLOP, PANT, PAGECON

DESCRIPTION:

It is necessary to "JMP IELMPCK" only before the first "JMP ELMPCK". IELMPCK sets the beginning address of VEBLOC; with every call of ELMPCK, this address is modified in order to pack the next variant element set successively. 100 sets of variant elements (700 words) may be stored in VEBLOC. The variant element sets in excess of 100 will be printed.
PURPOSE: To control the conversion of a pair of element cards into EBLOC format.

CALL SEQUENCE: TMA (WORD) JMP ELMRED JAZ (ERROR)

INPUTS: WORD = C/HLT, (Address of element card); C/HLT, (Block address)

OUTPUTS: \( N, M \) elements, \( \theta, t_o \), epoch, element type, in EBLOC

STORAGE REQUIREMENTS: 209 Cells

SUBROUTINES: Common: ELEM1, ELEM2, ETYPA, ETYPR, ETYPC, ETYPD, SFKFLT, SENGET, STLC, SEPSUB, PANT, CARDER, PAGECON, BCDFD, ARCTAN, ARCSIN, ARCCOS
Philco: FSQRT, FSIN, FCOS

DESCRIPTION:

The subroutine will validate the element type (A, B, C, D); if it is invalid, the normal exit will be taken with the A Reg = 0 after an error comment has been printed. If it is valid, the element cards will be unpacked and converted to \( N, M \) elements. These will be stored in EBLOC, as will the other values given in the EBLOC format. The subroutine will then set up the output buffer (EBUF) so that the one of following may be printed by another subroutine ELMOUT:

1. Element type A - classical elements
2. Element type B - \( r, \hat{r} \) elements
3. Element type C - orbit-station elements, classical elements, sensor coordinates
4. Element type D - radar-oriented elements, classical elements, sensor coordinates
PURPOSE: To convert an Error Prediction (ERFRED) Control Card.

CALL SEQUENCE: JMP ERPCON
              JAZ (ERROR)

INPUTS: Error Prediction (ERFRED) Control Card
        CCARD - See Description

OUTPUTS: CASETYP  ERPDOPT
         OTPFLAG  ERPS1
         APMFLAG  ERPS2
         DPVFLAG  ERPS3
         CAPPI    ERPI
         DELCAPP  OPOUT1
         CAPPF    OPOUT2 

STORAGE REQUIREMENTS: 72 Cells

SUBROUTINES: Common: SXSRCH, CARDER, PANT

DESCRIPTION:

Core location CCARD is checked to see that an ERFRED Control Card has not been converted for the case. If one has been processed, the current one will be rejected with an error comment and the A Reg = 0; if not, the card will be converted. If S1 and/or S2 = Δ, then S1 and/or S2 will be set = 3. The subroutine will then make the following tests:

1. S1 and S2 = 0
2. S1 or S2 NEG
3. I NEG
4. I ≥ 101

If any of the above are true, or if there was an error on conversion, the card will be rejected with an error comment and the A Reg = 0. If the card conversion is successful, Bit 5 will be set = 1 in core location CCARD.
PURPOSE: To convert classical elements to $N_M$ elements.

CALL SEQUENCE: TMA (WORD)
                JMP ETYPA

INPUTS: WORD = C/HLT, (Input Buffer Address); C/HLT, (Output Buffer Address)

Input Buffer (all floating point):
- **0**: Not used
- **1**: $a$ (Earth radii)
- **2**: $e$
- **3**: $i$ (Deg)
- **4**: $\Omega$ (Deg)
- **5**: $\omega$ (Deg)
- **6**: $M_0$ (Deg)

OUTPUTS: Output Buffer (all floating point):
- **0**: Not used
- **1**: $a_{X_0}$
- **2**: $a_{Y_0}$
- **3**: $h_{X_0}$ (Earth radii) $1/2$
- **4**: $h_{Y_0}$ (" ) $1/2$
- **5**: $h_{Z_0}$ (" ) $1/2$
- **6**: $L_0$ (Radians)

STORAGE REQUIREMENTS: 41 Cells

SUBROUTINES: Philco: FSIN, FCOS, FSQRT

DESCRIPTION:

Three input values are validated. If an error is found, the normal subroutine exit is not taken, but rather the exits indicated. It is necessary to set up error recovery at these core locations.

- **If** $a < 1.0$, then $\rightarrow$ ELERRA
- **If** $e \geq 1.0$, then $\rightarrow$ ELERRE
- **If** $i < 0$ or $i > \pi$, then $\rightarrow$ ELERRI

Having successfully validated these quantities, the subroutine will convert classical elements to $N_M$ elements with the formulas presented in the initialization portion of Section 3.
PURPOSE: To convert \( r, \dot{r} \) elements to \( N \) \( M \) elements

CALL SEQUENCE: TMA (WORD)
JMP ETYPB

INPUTS: WORD = C/HLT, (Input Buffer Address); C/HLT, (Output Buffer Address)

Input Buffer (all floating point):
+ 0 Not used
+ 1 \( x \) (Earth radii)
+ 2 \( y \) (Earth radii)
+ 3 \( z \) (Earth radii)
+ 4 \( \dot{x} \) (Radii/ke\(^{-1}\) min)
+ 5 \( \dot{y} \) (Radii/ke\(^{-1}\) min)
+ 6 \( \dot{z} \) (Radii/ke\(^{-1}\) min)

OUTPUTS:

Output Buffer (all floating point):
+ 0 Not used
+ 1 \( a_{x\mathrm{no}} \)
+ 2 \( a_{y\mathrm{no}} \)
+ 3 \( h_{x_0} \) (Earth radii\(^{1/2}\))
+ 4 \( h_{y_0} \) (Earth radii\(^{1/2}\))
+ 5 \( h_{z_0} \) (Earth radii\(^{1/2}\))
+ 6 \( L_{\theta} \) (Radians)

STORAGE REQUIREMENTS: 100 Cells

SUBROUTINES: Common: ARCTAN
Philco: FSQRT

DESCRIPTION:
The subroutine converts \( r, \dot{r} \) elements to \( N \) \( M \) elements with the formulas given in Section 3.
PURPOSE: To convert orbit-station elements to classical elements

CALL SEQUENCE: TMA (WORD)
                JMP ETYPC

INPUTS: WORD = C/HLT, (Input Buffer Address); C/HLT, (Output Buffer Address)

Input Buffer:
+ 0  Not used
+ 1  \( h_q \) (Km)
+ 2  \( e \) (Degrees)
+ 3  \( i \) (Degrees) \( \begin{cases} \text{(F)} \\ \{ \text{SOUTH} \Delta \text{SN} \} \end{cases} \) (BCD)
+ 4  \( h_0 \) (Degrees)
+ 5  \( \nu_0 \) (Degrees)
+ 6  \( \{ \text{NORTH} \Delta \text{NS} \} \) (BCD)

OUTPUTS: Output Buffer (all floating point):
+ 0  Not used
+ 1  \( a \) (Earth radii)
+ 2  \( e \)
+ 3  \( i \) (Degrees)
+ 4  \( \Omega \) (Degrees)
+ 5  \( \omega \) (Degrees)
+ 6  \( M_0 \) (Degrees)

STORAGE REQUIREMENTS: 80 Cells

SUBROUTINES: Common: ARCSIN, ARCTAN
Philco: FSIN, FCOS, FSQRT
DESCRIPTION:

Two input quantities are validated. If an error is found, the normal subroutine exit is not taken, rather the exits indicated will be taken. It is necessary to set up error recovery at these core locations.

If \( i = 0 \), then ELERRI
If \( e \geq 1 \), then ELERRE

Having successfully validated these quantities, the subroutine will convert orbit-station elements to classical elements with the formulas given in Section 3. During the conversion, it is possible to find an error in computing \( v_o, \beta_o, \) or \( K_o \). Therefore it is necessary to set up error recovery at core locations UOERR, BOERR, KOERR. These exits will be taken if the sine of the respective angle is \( > 1 \). Epoch time is zero and is stored in appropriate core location.
PURPOSE: To convert radar oriented elements to classical elements.

CALL SEQUENCE: TMA (WORD)  
               JMP ETYPD

INPUTS: WORD = C/HLT, (Input Buffer Address)  
         C/HLT, (Output Buffer Address)  
         Input Buffer (all floating point):  
         + 0 Not used  
         + 1 a (Earth radii)  
         + 2 e  
         + 3 i (Degrees)  
         + 4 h (Degrees)  
         + 5 ω (Degrees)  
         + 6 h (Degrees)  
         RHOO Po (Km) (F)

OUTPUTS: Output Buffer (all floating point):  
         + 0 Not used  
         + 1 a (Earth radii)  
         + 2 e  
         + 3 i (Degrees)  
         + 4 h (Degrees)  
         + 5 ω (Degrees)  
         + 6 M0 (Degrees)

STORAGE: 140 Cells

SUBROUTINES: Common: ARCCOS, ARCTAN  
              Philco: FSIN, FCOS, FSQRT, FATAN

DESCRIPTION: Three input quantities are validated. If an error is found,  
the normal subroutine exit is not taken, rather the exits indicated will be  
taken. It is necessary to set up error recovery at these core locations

If a < 1, then ELERRA  
If e ≥ 1, then ELERRE  
If i = 0, then ELERRI
Having successfully validated these quantities, the subroutine will convert radar oriented elements to classical elements with the formulas given in Section 3. During the conversion, it is possible to encounter $\rho_{\text{min}} > \rho_0 > \rho_{\text{max}}$, $|\cos v_0| > 1$, $|\cos \epsilon| > 1$, $|\sin \delta| > 1$, or $K_i < 0$. Therefore it is necessary to set up the respective error recovery locations ELERRO, VOERR, ELERREP, ELERRDG, and ELERRK.
PURPOSE: To retrieve and unpack one element set from EBLOC.

CALL SEQUENCE:

JMP EUNPCK
+1H JMP (ERROR)
+2H (NORMAL)

INPUTS:
EBLOC
LOCSAT = C/HLT, EBLOC; C/HLT, 0

OUTPUTS:
SATN HXO CO
ELNO HYO TO
AXNO HZO THGRTO
AYNO XLO YY

STORAGE REQUIREMENTS: 36 Cells

SUBROUTINES: Program: INITSAT, NXSAT

DESCRIPTION:

This subroutine uses "INITSAT" to initialize retrieval and "NXSAT" to retrieve the element set and other values from EBLOC. The ERROR return is obtained if the first word of EBLOC is zero, indicating no elements.
PURPOSE: To read the accounting clock and convert it to floating point days

CALL SEQUENCE: JMP FKLOK
TAM (RESULT 1)
TQM (RESULT 2)

INPUTS: None

OUTPUTS: RESULT 1 = Accounting clock - (floating point)
RESULT 2 = Accounting clock (4-bit BCD) - OYYMDDHMM M

STORAGE REQUIREMENTS: 11 Cells

SUBROUTINES: Common: AKLOK, BCDFD

DESCRIPTION:

The accounting clock reading is converted to floating point days since the beginning of the year and left in the A register; the accounting clock is left in the Q register in 4-bit BCD.
PURPOSE: Process a FLOAT card.

CALL SEQUENCE: JMP FLOAT

INPUTS: XR3 = card location

OUTPUTS: Floating correction

STORAGE REQUIREMENTS: 10 Cells

SUBROUTINES: Common: SFXFLT
SYS: STRIP

DESCRIPTION:

Uses the address in Col. 9-16, converted to octal, as the location to be corrected. Columns 25 to 40 are converted to floating point binary using SFXFLT and stored in the specified location.
PURPOSE: To set mode of subroutine SCANON to ignore or retrieve blanks

CALL SEQUENCE:

(1) To retrieve blanks:              (2) To ignore blanks:
    JMP GETBL                        JMP IGEL

INPUTS: None

OUTPUTS: None

STORAGE REQUIREMENTS: Part of SYS

SUBROUTINES: None
PURPOSE: To convert specified data words to BCD suitable for output purposes and output the converted group using PANT.

CALL SEQUENCE:

(1) TMA CWORD
JMP. GLOP.GLOP

This prepares specified data words for printing and jumps to PANT to put the line on magnetic tape.

(2) TMA CWORD
JMP GLOP.TGLOP

This prepares specified data words for TTY punching and jumps to TPANT to put image on magnetic tape.

(3) TMA CWORD
JMP GLOP.PGLOP

This prepares specified data words for card punching and jumps to PFANT to put image on magnetic tape.

INPUTS:

GLOP uses an indirect calling sequence, i.e., the parameters need not be in line in the user's coding. The control word is of the form:

L CWORD C/HLT,0;C/TIJL,FWORD, X1

FWORD is the first of a string of format words located in sequential core locations, and X1 may be any non-counting index register, except 1,2,3,4. If the programmer desires to put more than one sequence of format words together to specify a line of output, the code word has the format:

L CWORD C/TMA,CWORD2;C/TIJL,FWORD2,X1

CWORD2 is the location of another code word of the same form. When the left half of CWORD is zero, the end of the string of code words is signified. A string of CWORDs need not be in sequential core locations.
Example

TMA  CWORD
JMP  GLOP.GLOP

CWORD  C/TMA,CWOR2;C/TJL,FWORD
CWORD2 C/TMA,CWOR3;C/TJL,FWORD2
CWORD3 C/HLT,0;C/TJL,FWORD3

This calling sequence would cause GLOP to use as format words the three strings beginning at locations FWORD,FWORD2,FWORD3. The strings of format words would be processed in the order given. See Description for the details of the format words.

OUTPUTS: A 15 word output buffer (GLOP.BUFF) moved to the proper buffer in PANT.

STORAGE REQUIREMENTS: 210 Cells

SUBROUTINES: Common: PANT

DESCRIPTION:

The format words specify the various types of output desired and how they are to be positioned on the line. In general, the format words are of the form:

L FWOR MODE P*128 + F
FLAG DATA, Xi

Location FWOR is the first word of a sequence of format words - one word for each field on the line. The parameters which must be specified by the format words are:

1. P - the position of the field on the line.
2. F - the number of characters in the field.
3. DATA, Xj  - the location of the data.
4. MODE  - the mode (0 to 6) of conversion to alphanumeric.
5. FLAG   - the end of the format sequence.
6. The scale factor, if a fixed point number is involved.

Each conversion mode requires its own parameters; however, some parameters are common to all modes and will be discussed here.

The parameter P is used in all modes and is defined as the right-most print position of the data being processed. Its range is 0≤P≤128 for hard copy, 0≤P≤80 for cards, and 0≤P≤72 for teletype. The burden is on the user to insure enough room on the line for the information, without overlap. If an attempt is made to put more than one character in any one print position, the last character specified will be the one used.

The end of the format sequence is indicated by the command in the right half of the format word, "FLAG". If this command is "TMA" the GLOP conversion continues with the format word in the next sequential core location. If it is "CAM" the sequence is terminated and GLOP processes the next control word. This is specified in the left half of the previous control word. If the left half of the previous control word was a "HLT,0," all conversions have been finished and the line will be transferred from the line buffer to the output buffer. If the left half of the last control word was a "TMA, CWORDn", CWORDn is processed by GLOP.

Each conversion mode will now be taken up in turn.

Mode 0 - Alphanumeric Data - No conversion

Format: HLT P*128 + F
        FLAG DATA, Xj

F is the number of characters to be placed into the line buffer starting with the first character in location DATA, Xj. The last of these characters will be in position P. Xj may be any non-counting index register except 1X, 2X, 3X or 4X.
The range of $F$ is $0 \leq F \leq 120$.

**Mode 1** - Fixed point binary to fixed point decimal.

Format: 

- **JBT** $P \times 128 + F$
- **FLAG** DATA, $X_j$
- **D/X**

$F$ is the number of fractional digits to the right of the decimal point, the last being in print position $P$. As many places as are necessary to print the number, and its sign, are taken to the left of the decimal point. The total number of digits, both integral and fractional, may not exceed 14.

$X$ is the scale factor of the fixed point binary number in location DATA,$X_j$. $X_j$ may be any non-counting index register except $1X$, $2X$, $3X$ or $4X$.

**Mode 2** - Floating point binary to fixed point decimal.

Format: 

- **ICOZ** $P \times 128 + F$
- **FLAG** DATA, $X_j$

The format for **Mode 2** is exactly the same as for **Mode 1** except for the scale factor, which is not used. If $F$ is zero, no decimal point is printed.

**Mode 3** - Fixed point binary to floating point decimal.

Format: 

- **NOFL** $P \times 128 + F$
- **FLAG** DATA, $X_j$
- **D/X**

$F$ is the total field size, with the right-most character in position $P$. The printed number will look like $+mmm...mmmmpee$, where $m$ is a mantissa digit and $e$ is an exponent digit. The field is from the leading sign to the final $e$, and may not exceed 16.

Only the number of exponent digits required to express the number will be printed. If the exponent is zero, the mantissa takes the entire field.
X is the scale factor of the fixed point binary number in location DATA, Xj. Xj may be any non-counting index register except 1X, 2X, 3X or 4X.

**Mode 4** - Floating binary to floating point decimal.

Format: TIO P * 128 + F  
FLAG DATA, Xj

The format for Mode 4 is exactly the same as for Mode 3, with the exception of the scale factor, which is not used.

**Mode 5** - Fixed binary integer to decimal integer.

Format: TCM P * 128 + F  
FLAG DATA, Xj

F is the number of right shifts required to scale the word in location DATA, Xj 47; i.e., if one has an integer in the right half address (scaled 39), an F of 8 will cause the number to be scaled 47 before conversion. If the word in DATA, Xj is scaled 47, F should be = 0. The integer will be printed as a decimal integer with the low order digit in position P. As many characters as necessary will be used to express the number. Leading zeros or a plus sign will not be printed; if the number is negative, a leading minus sign will be printed.

**Mode 6** - Binary to octal.

Format: SKC P * 128 + F  
FLAG DATA, Xj

The binary word will be printed in octal in the form xxxx xxxx xxxx xxxx. Nineteen print positions are used. The right-most octal digit is placed in position P. F is not used.
PURPOSE: To output page headings on printed output.

CALL SEQUENCE: JMP HEAD

INPUTS: None

OUTPUTS: Page eject, system page heading, 2 line spaces

STORAGE REQUIREMENTS: 54 Cells

SUBROUTINES: Common: PANT, GLOP
PURPOSE: To control the conversion of a simulation parameter card into IBLOC format.

CALL SEQUENCE: JMP ICARD

INPUTS: XR3 = Location of card image
LIBLOC = C/HLT, IBLOC; C/HLT, IBLOC + 700
ISTB = C/HLT, IBLOC; C/HLT, 0 (initially)

OUTPUTS: Left address of ISTB is incremented by 7 and the right address of LOCI is set equal to it
ICOUNT is incremented by 1
Sets I card bit (Bit 3 = 1) in core location CARDS

STORAGE REQUIREMENTS: 13 Cells

SUBROUTINES: Common: SPARM, CARDER

DESCRIPTION:
The output listed is obtained only if no error is encountered during card conversion. The maximum number of cards that will be accepted is 100; those in excess of 100 will be rejected with an error comment.

Also see SPARM.
PURPOSE: To retrieve one set of simulation parameters from IBLOC

CALL SEQUENCE: (1) To initialize: 

```
JMP INITI
```

(2) Normal: 

```
JMP IGET
+1H JMP (END)
+2H (NORMAL)
```

INPUTS: 

```
LOCI = C/HLT, IBLOC; C/HLT, 0
Termination indicator for IBLOC must be 48/0
EIMTYP = 0000000X, X = Element type (A, B, C, D)
```

IBLOC

OUTPUTS: 

```
END = End of IBLOC, NORMAL: A Reg = STAID
```

STORAGE

```
STAID
OTYPE
VTYPE
DIRI (See IBLOC format for contents of core locations)
NUSEG
SEGNOS
HI
HF
IDELTAT
ROMAX
```

REQUIREMENTS: 30 Cells

SUBROUTINES: None

DESCRIPTION:

It is necessary to "JMP INITI" only before the first "JMP IGET". INITI sets the beginning address of IBLOC. With every call of IGET this address is modified to retrieve the next set of simulation parameters. If ELMTYP is not available, it is necessary to "JMP EUNPCK" to retrieve it. ELMTYP is tested; if it is = C or D, VTYPE is made non-visual (=0). The maximum number of sets of simulation parameters is 100.
PURPOSE: To read the Accounting Clock in 4-bit BCD format.

CALL SEQUENCE: JMP KLOK TAM (RESULT)

INPUTS: None

OUTPUTS: Result = OYYMDDHHMM.M (4-bit BCD)  
                 Implied decimal

STORAGE REQUIREMENTS: 10 Cells

SUBROUTINES: None

DESCRIPTION: Since the Accounting Clock does not contain the year, the last two digits of the year in core location ZYEAR is converted to 4-bit BCD and inserted in bits 4-11 of the result. ZYEAR must be updated yearly.
PURPOSE: To form a least squares matrix and solve the matrix equation \( Ax = B \) for \( x \); where

\[
A = \begin{bmatrix}
\sum C_1 C_1 & \sum C_1 C_2 & \cdots & \sum C_1 C_n \\
\sum C_2 C_1 & \sum C_2 C_2 & \cdots & \sum C_2 C_n \\
\vdots & \vdots & \ddots & \vdots \\
\sum C_n C_1 & \sum C_n C_2 & \cdots & \sum C_n C_n \\
\end{bmatrix}, \quad B = \begin{bmatrix}
\sum C_1 C_n + 1 \\
\sum C_2 C_n + 1 \\
\vdots \\
\sum C_n C_n + 1 \\
\end{bmatrix}
\]

CALL SEQUENCE: (1) To set \( n \)
TMA CWORD
JMP CHGNNXN

\text{CWORD} = C/HLTR, n \quad (n \leq 7)

(2) To initialize the routine (Zero A and B matrices)
JMP LSQ

This will jump to a routine call FUNCT for the first set of terms \( C_1 \) to \( C_{n+1} \)

(3) To add to the matrix A and B
JMP LSQR

\( C_1 \) to \( C_{n+1} \) are to be located in cells TERMS to TERMS + n.
This will jump to FUNCT for the next set of C's.

(4) To solve the matrix equation
JMP LSQS

Solves the matrix equation, leaving the solution in LSQX to LSQX + n - 1.
(Continued)

STORAGE REQUIREMENTS: 141 Cells

SUBROUTINES: Philco: FMAIN, FMAMU

DESCRIPTION:

The top half of matrix A is accumulated at each entry to LSQR. When entry is made to LSQS, the terms of A are placed in the bottom half, then entry is made to the standard Philco matrix inversion and multiplication subroutines.
PURPOSE: To control the conversion of a standard deviation and bias card into SGBLOC format.

CALL SEQUENCE: JMP MCARD

INPUTS: XR3 = Location of card image
LSGBLOC = C/HLT, SGBLOC; C/HLT, SGBLOC + 900
SIGSTB = C/HLT, SGBLOC; C/HLT, 0 (Initially)

OUTPUTS: The left address of SIGSTB is incremented by 9 and the right address of LOCSIG is set equal to it.
SGCOUNT is incremented by 1
Sets M card bit (bit 4 = 1) in core location CARDS

STORAGE REQUIREMENTS: 11 Cells

SUBROUTINES: Common: CARDER, STDEV

DESCRIPTION:

The output listed is obtained only if no error is encountered during card conversion. The maximum number of cards that will be accepted is 100; those in excess of 100 will be rejected with an error comment.

Also see STDEV
PURPOSE: To convert a Monte Carlo (MOCARO) Control Card

CALL SEQUENCE: JMP MCCON
               JAZ (ERROR)

INPUTS: MOCARD Control Card
         CCARD
         KMAX = D/100(T47)

OUTPUTS: K - Number of contaminated observations to be generated (T47)
         FIRSTRN - Beginning random number (T47)
         COFLAG - Monte Carlo output option (T47)

STORAGE REQUIREMENTS: 35 Cells

SUBROUTINES: Common: SFXINT, CARDER, PANT

DESCRIPTION:

Core location CCARD is checked to see that a Monte Carlo Control Card has not been converted for the case. If one has been processed, the current one will be rejected with an error comment and the A Reg = 0; if not, the card will be converted. K will be tested to see that it is less than KMAX. If it is not, or if there is an error on conversion, an error comment will be printed and the subroutine will exit with A Reg = 0. If the card conversion is successful, Bit 2 will be set = 1 in core location CCARD.
PURPOSE: To compute position and velocity at a specific time.

CALL SEQUENCE: JMP MNREP

INPUTS (All floating point):

- XJGRCF: $k_e \sqrt{\mu J a_e^2}$ or $1.20717162 \times 10^{-4}$ \((\text{radii})^{7/2}\)
- CO: Perigee drag parameter $C_0$ (days/rev)
- HXO: Inertial X component of angular momentum $h_x (\text{Earth radii})^2 k_e^{-1} \text{min}$
- HYO: Inertial Y component of angular momentum $h_y (\text{Earth radii})^2 k_e^{-1} \text{min}$
- HZO: Inertial Z component of angular momentum $h_z (\text{Earth radii})^2 k_e^{-1} \text{min}$
- AXNO: N component of $a = e P \times N$
- AYNO: M component of $a = e P \times N$
- XLO: Mean longitude $L(\text{Radian})$
- T: Elapsed time since epoch conditions $t - t_0$ (min)

OUTPUTS (All floating point):

- X: Inertial X component of position at time $t$ \(x \text{ Earth radii}\)
- Y: Inertial Y component of position at time $t$ \(y \text{ Earth radii}\)
OUTPUTS (All floating point): (continued)

- **Z**: Inertial Z component of position at time $t$
- **XDOT**: Inertial X component of velocity at time $t$
- **YDOT**: Inertial Y component of velocity at time $t$
- **ZDOT**: Inertial Z component of velocity at time $t$

**STORAGE REQUIREMENTS**: 200 Cells

**SUBROUTINES**: Philco: FSIN, FCOS, FSORT

**DESCRIPTION**:

Given the six orbital quantities, $a_{xN}$, $a_{yN}$, $h_x$, $h_y$, $h_z$ and $L$, along with the quantities $t - t_0$, $C_0$, and $XJGRCF$, MNREP will compute and output position $\mathbf{r}$ and velocity $\dot{\mathbf{r}}$. The input quantity, $XJGRCF = k \sqrt{\mu} J_{22}^2$, controls the method of computation of $\mathbf{r}$ and $\dot{\mathbf{r}}$ (i.e., $XJGRCF = 1.20717162 \times 10^{-4}$ includes the perturbation effects in the computation of $\mathbf{r}$ and $\dot{\mathbf{r}}$, $XJGRCF = 0$ bypasses all perturbation effects and computes the two body $\mathbf{r}$ and $\dot{\mathbf{r}}$). By means of initializing checks, the routine establishes whether the incoming element set had been used previously. If so, it bypasses a portion of the computation that would be redundant, thus saving computation time.
The formulation used in the MNREP subroutine is presented below. Reference may also be made to the enclosed flow diagram for the logical sequence of computation.

(1) Compute the preliminary quantities:

\[
\begin{align*}
    p_o &= h_x^2 + h_y^2 + h_z^2 \\
    e_o &= a_x^2 + a_y^2 \\
    a_o &= p_o / (1 - e_o^2) \\
    n_o &= \frac{k_e \nu / a_o^{3/2}} \\
    w_o &= \frac{h_o}{\sqrt{p_o}} \\
    \sin i &= \sqrt{1 - w_o^2} \\
    \cos i &= w_o \\
    i &= \tan^{-1}(\sin i / \cos i) \quad 0 \leq i \leq \pi \\
    \cos \Omega_o &= -w_o / \sin i \\
    \sin \Omega_o &= w_o / \sin i \\
    \Omega_o &= \tan^{-1}(\sin \Omega_o / \cos \Omega_o) \\
    q_o &= a_o (1 - e_o)
\end{align*}
\]
(2) For simplified general perturbations computation, i.e. when XJGRCF ≠ 0, compute the perturbative coefficients c", k_e' and k_e L'_so:

\[
c" = -360 \frac{n_0^2 C_0}{\pi^2}
\]

\[
k_e J' = k_e \sqrt{\mu} \frac{J^2}{a_0^3/2}
\]

\[
k_e L'_so = \frac{[k_e \sqrt{\mu} J^2 / a_0^{7/2}]}{[3 - 5e^2 - \cos i \left(1 - \frac{3}{2} e^2\right) - \sin^2 i(4 - \frac{27}{4} e^2)]}
\]

In two body computation, i.e. when XJGRCF = 0, the above coefficients are identically zero.

(3) Compute the perturbed orbital elements:

\[
a = a_o \left[1 - \frac{4}{3} c" (t-t_o)\right]
\]

\[
n = k_e \sqrt{\mu} / a^{3/2}
\]

\[
e = 1 - a_o / a, \text{ FOR } a > q_o
\]

\[
e = 0, \text{ FOR } a < q_o
\]

\[
p = q_o (1 + e)
\]

\[
\frac{d\Omega}{dt} = -k_e J' \cos i \left(1 - \frac{3}{2} e^2\right)
\]

\[
\Omega = \Omega_o + \frac{d\Omega}{dt} (t-t_o)
\]
\[
\frac{d\omega}{dt} = k_e \frac{J_1}{2} (5 \cos^2 i - 1)(1 - \frac{3}{2} e^2)
\]

\[
\omega_s = \omega - \omega_o = \frac{d\omega}{dt} (t - t_o)
\]

\[
a_x N = \frac{e}{e_o} (a_x \cos \omega - a_y \sin \omega)
\]

\[
a_y N = \frac{e}{e_o} (a_x \sin \omega + a_y \cos \omega)
\]

\[
L = L_0 + (n_o + k e_{s_o}) (t - t_o) + n_o c'' (t - t_o)^2
\]

(4) Compute U and the components of the vectors M, N, W:

\[
W_x = \sin \Omega \sin i
\]

\[
W_y = \cos \Omega \sin i
\]

\[
W_z = \cos i
\]

\[
M_x = -\sin \Omega \cos i
\]

\[
M_y = \cos \Omega \cos i
\]

\[
M_z = \sin i
\]

\[
N_x = \cos \Omega
\]

\[
N_y = \sin \Omega
\]

\[
N_z = 0
\]

\[
U = L - \Omega, \text{ IF } W_z \geq 0
\]

\[
U = L + \Omega, \text{ IF } W_z < 0
\]
(5) Compute \((E + \omega)\) by iteration:

\[
E + \omega = U + a_x \sin (E + \omega) - a_y \cos (E + \omega)
\]

(6) Compute the additional auxiliary quantities:

\[
e \cos E = a_x \cos (E + \omega) + a_y \sin (E + \omega)
\]

\[
e \sin E = a_x \sin (E + \omega) - a_y \cos (E + \omega)
\]

\[
r = a (1 - e \cos E)
\]

\[
\dot{r} = \left(\sqrt{\frac{a}{r}}\right) e \sin E
\]

\[
r \dot{\nu} = \left(\sqrt{\frac{a}{r}}\right) \sqrt{1 - e^2}
\]

\[
\cos u = \frac{a}{r} \left[\cos (E + \omega) - a_x \sin \left(\frac{e \sin E}{1 + \sqrt{1 - e^2}}\right) + a_y \right]
\]

\[
\sin u = \frac{a}{r} \left[\sin (E + \omega) - a_y \sin \left(\frac{e \sin E}{1 + \sqrt{1 - e^2}}\right) - a_x \right]
\]

(7) Compute the components of the unit vectors \(U\) and \(V\):

\[
U = N \cos i + N \sin u
\]

\[
V = -N \sin u + N \cos u
\]

(8) The position and velocity vectors are then obtained directly:

\[
r = r U \rightarrow x, y, z
\]

\[
\dot{r} = \dot{r} U + r \dot{\nu} V \rightarrow \dot{x}, \dot{y}, \dot{z}
\]
PURPOSE: To obtain a number randomly from a normal distribution.

CALL SEQUENCE: JMP NODN
TQM (RESULT)

INPUTS: See Description

OUTPUTS: RESULT = Normal deviate (Floating point)

STORAGE REQUIREMENTS: 79 Cells

SUBROUTINES: Common: REDN

DESCRIPTION:

Since this subroutine uses REDN, it is necessary to initialize it as required (see REDN). Given a random number between 0 and 1, NODN will do a table look-up and interpolation to find the normal deviate.
PURPOSE: To control the conversion of a system observation card (internal format, Col 80 = 0) into OBLOC or COBLOC format.

CALL SEQUENCE: (1) For OBLOC: 
(2) For COBLOC:

JMP OBCARD    JMP OCCARD

INPUTS: See: OBSCRD

OUTPUTS: See: OBSCRD

STORAGE REQUIREMENTS: 4 Cells

SUBROUTINES: Common: OOCARD, OBSCRD, COBCRD

DESCRIPTION:

OBCARD modifies subroutine OBSCRD to accept system observation cards; then transfers control to OBSCRD. Subroutine OOCARD is used in place of OBSERV. The OBCARD entrance is used in converting cards for OBLOC, and the OCCARD entrance is used in converting cards for COBLOC.
PURPOSE: To pack one simulated observation into OBLOC

CALL SEQUENCE: 

(1) To initialize: 

JMP IOBPCK

(2) Normal: 

JMP OBPKCK

+ 1H JMP (END)

+ 2H (NORMAL)

INPUTS: 

LOBLOC = C/HLT, OBLOC; C/HLT, OBLOC + 3000

STAID

OTYPE

RANGE (See OBLOC format for contents of core locations)

ALPHA

DELTA

RODOT

T

OUTPUTS: One simulated observation in OBLOC (See OBLOC format)

END = OBLOC full (See Description)

STORAGE REQUIREMENTS: 48 Cells

SUBRoutines: 

Common: PANT, GLOP, PAGECON

Program: OBPKCK, OBPKCA

DESCRIPTION:

It is necessary to "JMP IOBPCK" only before the first "JMP OBPKCK". IOBPCK sets the beginning address of OBLOC. With every call of OBPKCK this address is modified in order to pack the next observation successively; a program subroutine OBPKCK packs one observation. 500 observations may be stored in OBLOC. Observations in excess of 500 will be printed by program subroutine OBPKCA.
Purpose: To control the conversion of a standard SPADATS observation card into OBLOC or COBLOC format.

Call Sequence:
(1) For OBLOC: 
\[ \text{JMP OBSCRD} \]

(2) For COBLOC: 
\[ \text{JMP COBCRD} \]

Inputs:
\[ \text{XR3} = \text{Location of card image} \]
\[ \text{EBLOC} \]

For OBLOC entrance:
\[ \text{LOBLOC} = C/HLT, \text{OBLOC}; C/HLT, \text{OBLOC} + 3000 \]
\[ \text{OBSSTB} = C/HLT, \text{OBLOC}; C/HLT, 0 \text{ (initially)} \]

For COBLOC entrance:
\[ \text{LCOBLOC} = C/HLT, \text{COBLOC}; C/HLT, \text{COBLOC} + 3000 \]
\[ \text{COBSTB} = C/HLT, \text{COBLOC}; C/HLT, 0 \text{ (initially)} \]

Outputs:
(1) For OBLOC entrance:
Left address of OBSSTB incremented by 6 and right address of LOBONS set equal to it. OCOUNT incremented by 1.

(2) For COBLOC entrance:
Left address of COBSTB incremented by 6 and right address of LOCCOB set equal to it. COCOUNT incremented by 1.

Bit 46 set to 1 in location CARDS to indicate a successful read.

Storage Requirements: 45 Cells

Subroutines: Common: OBSERV, PANT, CARDER
DESCRIPTION:

OBCRD and COBCRD are similar subroutines, differing only as to which block is used for output: OBLOC (Observation Block) or COBLOC (Contaminated Observation Block). It is necessary for element cards to be entered before observation cards. If not, the observation card is rejected and an error comment is printed. Standard SPADATS observation cards are not allowable for element types C and D; they will be rejected with an error comment if encountered. The output listed is obtained only if no error is encountered during card conversion. The maximum number of cards that will be accepted is 500; those in excess of 500 will be rejected with an error comment.

Also, see OBSERV.
PURPOSE: To convert a standard SPADATS observation card into OBLOC or COBLOC format.

CALL SEQUENCE: TMA (WORD)  
JMP OBSERV  
JAZ (ERROR)

INPUTS: WORD = C/HLT, (card address); C/HLT (Block address)  
EBLOC

OUTPUTS: ERROR = Error on conversion  
One observation entered in OBLOC or COBLOC

STORAGE REQUIREMENTS: 109 Cells

SUBROUTINES: Common: CARDER, PANT, SXRSRCH, BCDFD

DESCRIPTION:

This subroutine unpacks SPADATS observation cards into OBLOC or COBLOC. If an error is found, a comment will be printed and the normal exit will be taken with the A Reg. = 0.
PURPOSE: To retrieve one simulated observation from OBLOC.

CALL SEQUENCE:

(1) To initialize:
   JMP INITOBS

(2) Normal:
   JMP OBSGET
   +1H JMP (END)
   +2H (NORMAL)

INPUTS:
OBLOC
LOCOBS = C/HLT, OBLOC; C/HLT, 0
Termination indicator for OBLOC must be 48/0

OUTPUTS:
   END = End of simulated observations
   NORMAL A Reg = STAID
   OTYPE
   RANGE (See OBLOC format for contents of core locations)
   ALPH
   DELTA
   RODOT
   T

STORAGE
REQUIREMENTS: 20 Cells

SUBROUTINES: None

DESCRIPTION:

It is necessary to "JMP INITOBS" only before the first
"JMP OBSGET". INITOBS sets the beginning address of OBLOC. With every
call of OBSGET this address is modified to retrieve the next successive
simulated observation. The maximum number of simulated observations is 500.
PURPOSE: To convert a system observation card (internal format, col 80 = 0) into OBLOC or COBLOC format

CALL SEQUENCE: TMA (WORD)
                JMP OOCARD
                JAZ (ERROR)

INPUTS: WORD = C/HLT, (Card address); C/HLT (Block address)

OUTPUTS: ERROR = Error on conversion
          One observation entered in OBLOC or COBLOC

STORAGE REQUIREMENTS: 21 Cells

SUBROUTINES: Common: SXSRCH
PURPOSE: To provide a central control for printed output formats.

CALL SEQUENCE: TMA (WORD)
                JMP PAGECON

INPUTS: WORD = C/HLT, (N); C/HLT, 0, (N = number of lines of output)

OUTPUTS: A Reg = 0. Start of new page.

STORAGE REQUIREMENTS: 7 Cells

SUBROUTINES: Common: HEAD, PANT, GLOP

DESCRIPTION:

This subroutine requires initialization by subroutine "PAGEINT" at the start of every job. It is recommended to use PAGECON at least after every 5 lines of output. To force a new page, set N = 70. The subroutine keeps a line count for the current output page. When the count is ≥ 55, it will eject the page, put out a new heading, space 2 lines, and exit with the A Reg = 0.
PURPOSE: To initialize HEAD and PAGECON.

CALL SEQUENCE: JMP PAGEINT

INPUTS: None

OUTPUTS: None

STORAGE REQUIREMENTS: 13 Cells

SUBROUTINES: Common: AKLOK, BCDCCLK, HEAD

DESCRIPTION:

This subroutine initializes HEAD and PAGECON in the following manner:

1. Sets page number to 1
2. Uses Accounting Clock to set up BCD date and time of the start of run
3. Sets up the case ID and sequence number
4. Outputs the first page heading and sets the line count
NAME: PANT

PURPOSE: To edit output and control writing of output buffers on magnetic tape.

STORAGE REQUIREMENTS: 806 Cells

SUBROUTINES: None

DESCRIPTION:

PANT edits all alphanumeric output data properly for the mode desired, accumulates each type in a separate buffer, writes out the buffer onto magnetic tape when it is full, and resets the buffer to the appropriate filler characters.

The three modes of output that PANT can edit are hard-copy (printer) teletype (TTY) and punched cards in code-mode. The hard-copy is accumulated in PANT, BUFF; TTY in PANT.BBUF; and punched cards in PANT.PBUF. When processing the output tape off line, hard copy is in data select 0; punched cards in data select 2, and teletype in data select 4. The punched cards are in code-mode with the PCC (punched card controller) set to 10 words/card, 12 cards/block, and the "Sense Control Characters Switch" set to ignore.

PANT contains all its own output processing logic, including TIOs and skip check orders. Mode 3 writes are used which will normally handle parity and sprocket errors. In the case of block marks, PANT rewrites the block and indicates via a flex typeout that an improper block mark was encountered. Duplicate output may result in this case. Errors requiring operator action are indicated on the flexewriter. If PANT reissues an order ten times without successfully writing the block, it will rewind the output tape with lockout (no wrapup), and type on the flex calling for a new output tape.

PANT has many entrances which are explained in detail on the following pages.
CALL SEQUENCE: JMP PANT.PAGE

INPUTS: None

OUTPUTS: Page eject on hard copy

DESCRIPTION:

It places a page eject in the hard copy output buffer followed by an end-of-line control character.
CALL SEQUENCE: TMA (WORD)
               JMP PANT.PINT

INPUTS: WORD = C/HLT,N;C/HLT, TABLE Form 1
       or    N/XT23         Form 2

In Form 1, the sum of TABLE + N is the location of a cell containing the desired tape number (O/T23) e.g. TABLE + 5 contains 0/5T23.

In Form 2, X = tape number desired

OUTPUTS: PANT initialized with buffers and counters all preset.

DESCRIPTION:

PINT initializes all IO and skip check orders to the tape number specified. It also sets all counters to the beginning address of the three output blocks (BUFF, BBUF, PBUF). It also sets the first word of each buffer to the proper data select (0 for printing, 2 for punched cards, 4 for TTY) and the remaining words in the buffer to the proper fill characters.

PINT will destroy any information contained in PANT's output buffers.
CALL SEQUENCE:  TMD  (WORD)
                JMP  PANT.PANT

INPUTS:        WORD = C/HLT,N;C/HLT,BUFFER
                N = No. of Words
                BUFFER = Beginning address of alphanumeric data

OUTPUTS:       Alphanumeric data in hard-copy output buffer or written
                on magnetic tape

DESCRIPTION:

    PANT moves N words from Buffer to Buffer + N - 1 into
the output buffer for hard-copy (PANT.BUFF). When PANT.BUFF contains
113 words or more, PANT writes it on magnetic tape, and resets it to
fillers plus a data select word and an end of block word.
CALL SEQUENCE: TMD (WORD)
JMP PANT.TPANTA
or
JMP PANT.TPANT

INPUTS: WORD = C/HLT, N;C/HLT, BUFFER
N = No. of words
BUFFER = Beginning address of alphanumeric data

PANT.TPANT assumes N = 15, BUFFER = GLOP.BUFF

OUTPUTS: Alphanumeric data on the teletype output buffer or
written on magnetic tape.

DESCRIPTION:

PANT moves N words from Buffer to Buffer + N - 1 into the
teletype output buffer (PANT.BBUFF). When PANT.BBUFF contains 127 words
plus a data select word, PANT writes it on magnetic tape and resets the
buffer to letters characters (37g).

If the user wants to use the same GLOP.BUFF output which
has just been put on hard copy for teletype output, he should jump to
PANT.TPANT. This entrance assumes N = 15, BUFFER = GLOP.BUFF.

In order to minimize the number of characters in a line,
TPANT will recognize a 32g (filler character) as the end of the teletype
line and convert it to two carriage returns and a line feed (555575g).
If the user does not have a 32 in his output data, TPANT will put the two
carriage returns and line feed after the last character of the last word,
(8th character of Buffer + N - 1). When using TPANT, one should always
output the 32g character immediately following the last column used to
minimize the amount of teletype tape punched and the amount of transmission
time necessary to send the message. This is especially important when using
GLOP.BUFF either via GLOP.TGLOP or PANT.TPANT.
CALL SEQUENCE:  TMD (WORD)
                JMP PANT.PPANT

INPUTS:       WORD = C/HLT, N;C/HLT, BUFFER
              N = No. of words
              BUFFER = Beginning address of alphanumeric data

OUTPUTS:      Alphanumeric data in the punched card output buffer or
              written on magnetic tape in proper format for punching.

DESCRIPTION:

PPANT moves N words from Buffer to Buffer + N - 1 into
the punched card output buffer (PANT.PBUF). It then sets the next "10-N"
locations equal to blanks. If N is greater than 10, PPANT only accepts
the first 10 words of BUFFER. When PANT.PBUF has 12 card images (or 120
words plus a data select word), it is written on magnetic tape and reset
to fillers (32g). Cards are punched with the PCC (punch card controller)
set at 10 words/card, 12 cards/block, and sense control characters to
ignore.
CALL SEQUENCE: JMP PANT.SPACE or TMA (WORD) JMP PANT.SPACER

INPUTS: WORD = C/HLT, N
N = Number of spaces desired

PANT.SPACE assumes N = 1

OUTPUTS: Spaces on hard copy

DESCRIPTION:

Puts N end-of-line characters in the output buffer in PANT (PANT.BUFF).
CALL SEQUENCE: JMP PANT.TSPACE
or
TMD (WORD)
JMP PANT.TSPACER

INPUTS: WORD = C/HLT, N
        N = Number of spaces desired

PANT.SPACE is the special case where N is assumed = 1

OUTPUTS: One or more line feeds on teletype output

DESCRIPTION:

The number of line feeds specified are output with a
double carriage return, preceding the last line feed. If N = 0, no
output is done and a normal return is executed.
CALL SEQUENCE: JMP PANT.FINISH

INPUTS: None

OUTPUTS: All hard copy output on magnetic tape with a conditional stop character.

DESCRIPTION:

If the hard-copy output buffer is partially full, PANT writes it on magnetic tape and resets the buffer to fillers. Then, in all cases, a conditional stop is inserted and the output buffer is written on tape and reset to filler characters.
CALL SEQUENCE: JMP PANT.TFIN

INPUTS: None

OUTPUTS: All TTY output on magnetic tape with a conditional stop character.

DESCRIPTION:

If the TTY output buffer is partially full, it is written on magnetic tape and reset to letters characters. Then, in all cases, a conditional stop is inserted and the output buffer is written on tape and reset to letters characters.
CALL SEQUENCE:  JMP  PANT.PFIN

INPUTS:  None

OUTPUTS:  All punched card output on magnetic tape with a conditional stop character.

DESCRIPTION:

If the punched card output buffer is partially full, PANT writes it on magnetic tape and resets it to fillers. Then, in all cases, a conditional stop character is inserted and the output buffer is written on tape and reset to filler characters.
CALL SEQUENCE: JMP PANT.ALLFIN (Conditional stops)
 or
      JMP PANT.XFIN  (Absolute stops)

INPUTS: None

OUTPUTS: All output data on magnetic tape with absolute or conditional stops.

DESCRIPTION:

This is equivalent to a jump to PANT.FINISH, PANT.TFIN, PANT.PFIN. If PANT.XFIN is used, absolute, rather than conditional stops, will be output.
PURPOSE: Output image of Col. 25 to 80 of PRINT card to hard-copy.

CALL SEQUENCE: JMP PRINT

INPUTS: XR3 = card location

OUTPUTS: XR3 = card location + 3
        Alphanumeric data output.

STORAGE REQUIREMENTS: 4-1/2 Cells

SUBROUTINES: Common: CARDER, PANT, PAGECON

DESCRIPTION:

Outputs the 7 words from card location + 3 to card location + 9 to hard-copies, then outputs one space.
PURPOSE: To generate a random number.

CALL SEQUENCE:

(1) To initialize:
  TMA (WORD)
  JMP REDNI

(2) Normal:
  JMP REDN
  TAM (RESULT1)
  TQM (RESULT2)

INPUTS: WORD = First random number of the form 4K + 1, K is a positive integer (fixed point)

OUTPUTS: RESULT1 = Fixed point random number
          RESULT2 = Floating point random number

STORAGE REQUIREMENTS: 9 Cells

SUBROUTINES: None

DESCRIPTION:

It is necessary to initialize only once for each case or for each time a new beginning random number is desired. REDN saves the current random number and uses it to generate the next random number.
PURPOSE: To extract a variable field on an input card.

CALL SEQUENCE:

(1) For first field:
   JMP SCAN

(2) For successive fields:
   JMP SCANON

INPUTS:
   Input card

OUTPUTS:
   W1 { BCD field, blanks suppressed, right justified
   W2 } with leading zeros.

S1CHARCT = Left address = character count

A Reg = break character

STORAGE REQUIREMENTS: Part of SYS

SUBROUTINES: None

DESCRIPTION:

This subroutine will extract variable fields for columns 25-80; maximum allowable field length is 16 BCD characters. To extract the first field, "JMP SCAN"; for successive fields, "JMP SCANON". The subroutine will search field, suppressing blanks and storing valid characters into core locations W1 and W2 until a break character is found (.,$./;). The character count is kept in the left address of core location S1CHARCT. Upon return, the A register will contain the break character, right justified with leading zeros.

If blanks are desired, precede "JMP SCANON" by a "JMP GETBL". If blanks are desired on the first field, move core location COL25 to core location SCANC, "JMP GETBL", and begin with "JMP SCANON" rather than "JMP SCAN".
PURPOSE: To convert a sensor card into SBLOC format.

CALL SEQUENCE:

<table>
<thead>
<tr>
<th>Command</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>TMA</td>
<td>(WORD)</td>
</tr>
<tr>
<td>JMP</td>
<td>SCARD</td>
</tr>
<tr>
<td>JAZ</td>
<td>(ERROR)</td>
</tr>
<tr>
<td></td>
<td>(NORMAL)</td>
</tr>
</tbody>
</table>

INPUTS:
WORD = C/HLT, (Card address); C/HLT, (Block address)

OUTPUTS:
ERROR = Error on conversion
One sensor entered in SBLOC.

STORAGE REQUIREMENTS:
60 Cells

SUBROUTINES:
Common: SFXFLT, SFXFLTA, CARDER, PANT
Program: SCONV
Philco: FSIN, FCOS, FSQRT

DESCRIPTION:
This subroutine unpacks sensor cards into SBLOC. It also computes X/cos θ and Z by using program subroutine SCONV; these values are also stored in SBLOC. If an error is found, a comment will be printed and the normal exit will be taken with the A Reg = 0.
PURPOSE: To convert floating point days to a BCD date

CALL SEQUENCE:
TMA (WORD)
JMP SDKLOK
TAM (RESULT1)
TQM (RESULT2)

INPUTS: WORD = Floating point days since beginning of year

OUTPUTS: RESULT1 = △YYMMDD (6-Bit BCD)
RESULT2 = Fraction of days (floating point)

STORAGE REQUIREMENTS: 122 Cells

SUBROUTINES: None
PURPOSE: To control the conversion of a sensor card into SBLOC format

CALL SEQUENCE: JMP  SENCARD

INPUTS: 
- XR 3 = Location of Card image
- LSBLOC = C/HLT, SBLOC; C/HLT, SBLOC + 600
- SENSTB = C/HLT, SBLOC; C/HLT, 0 (Initially)

OUTPUTS: The left address of SENSTB is incremented by 6 and the right address of LOCSEN is set equal to it. SCOUNT is incremented by 1. Bit 2 of location CARDS is set to 1.

STORAGE REQUIREMENTS: 11 Cells

SUBROUTINES: Common: CARDER, SCARD

DESCRIPTION:
The output listed is obtained only if no error is encountered during the card conversion. The maximum number of cards that will be accepted is 100. Those in excess of 100 will be rejected with an error comment.
PURPOSE: To retrieve sensor data from SBLOC.

CALL SEQUENCE:

(1) To initialize:
    JMP INITSEN

(2) To retrieve sensors sequentially:
    CA
    JMP SENGET
    + 1H JMP (END)
    + 2H (NORMAL)

(3) To retrieve a specific sensor:
    TMA (WORD)
    JMP SENGET
    + 1H JMP (ERROR)
    + 2H (NORMAL)

INPUTS: LOCSEN = C/HLT SBLOC; C/HLT, 0
         Termination indicator for SBLOC must be 48/0
         SCOUT = C/HLT, N; C/HLT, 0 N = No. of Sensors in SBLOC
         WORD = AAAAANNN, N = Sensor Number
         SBLOC

OUTPUTS: END = End of SBLOC
         ERROR = Sensor not in SBLOC
         XLAMBA
         PHIRD
         OALT
         XOVT
         CAPZ
         STAID
         (See SBLOC format for contents of core locations)

STORAGE

REQUIREMENTS: 27 Cells

SUBROUTINES: None

DESCRIPTION: This subroutine may be used in two ways: To retrieve a specific sensor or to retrieve the next sequential sensor. To retrieve a specific sensor use call sequence (3); no initialization is required. If retrieving sequential sensors, it is necessary to "JMP INITSEN" only before the first use of call sequence (2). INITSEN sets the beginning address of SBLOC. With every call of SENGET (2), this address is modified to retrieve the next sensor. The maximum number of sensors is 100.
PURPOSE: To separate a floating point number into its integral and fractional parts.

CALL SEQUENCE: TMA (WORD) JMP SEPSUB

INPUTS: WORD = Floating point number

OUTPUTS: A Reg. = Integer (F) Q Reg. = Fraction (F)

STORAGE REQUIREMENTS: 18 Cells

SUBROUTINES: None
PURPOSE: To set the mode of the MNREP subroutine.

CALL SEQUENCE: TMA (WORD)
               JMP SETJC

INPUTS: WORD = \{00000000, 00000001\} Allow perturbations
          \{00000000 \angle, 00000001\} Suppress perturbations

OUTPUTS: XJGRCF = \{0, 1.2071762 \times 10^{-4}\} Suppress perturbations
          \{1.2071762 \times 10^{-4}\} Allow perturbations

STORAGE REQUIREMENTS: 4 Cells

SUBROUTINES: None

DESCRIPTION:

The core location XJGRCF is set as a parameter for the MNREP subroutine to determine whether the two-body or the simplified general perturbations approach is used for predicting orbital position and velocity.
PURPOSE: To convert a BCD number to a floating point number.

CALL SEQUENCE:

(1) If ≤ 8 BCD characters:
   TMQ (WORD)
   JMP SFXFLTA
   JAZ (ERROR)
   TAM (RESULT)

(2) If > 8 and ≤ 16 BCD characters:
   TMA (WORD 1)
   TMQ (WORD 2)
   JMP SFXFLT
   JAZ (ERROR)
   TAM (RESULT)

INPUTS: WORD = ≤ 8 BCD Character number
         WORD 1 > 8 and ≤ 16 BCD Character number
         WORD 2

OUTPUTS: RESULT - floating point number

STORAGE REQUIREMENTS: 110 Cells

SUBROUTINES: None

DESCRIPTION:

The input may be of the following forms:

±xx. xx
±xx. xx ± NN
±xx. xx E ± NN

All blanks are ignored. Leading zeros are ignored; trailing zeros are significant.
PURPOSE: To retrieve one set of standard deviations and biases from SGBLOC.

CALL SEQUENCE:

(1) To initialize
   JMP INITSIG

(2) To retrieve sequentially:
   JMP INITSIG
   JMP SIGGET
   + 1H JMP (END)
   + 2H (NORMAL)

(3) To retrieve specifically:
   JMP SIGGET
   + 1H JMP (ERROR)
   + 2H (NORMAL)

INPUTS:

LOC SIG = C/HLT, SGBLOC: C/HLT, 0
Termination indicator for SGBLOC must be 48/0
SGCOUNT = C/HLT, N; C/HLT, 0 N = Number of sets in SGBLOC
WORD = △△△△△ NNN, N = Sensor Number

OUTPUTS:

END = End of SGBLOC
ERROR = Set not in SGBLOC
STAID BLASRHO
SIGRHO BIASALP
SIGALP BIASDLT
SIGDLT BLASRRT (See SGBLOC Format for contents of
SIGRT core locations)

STORAGE REQUIREMENTS: 24 Cells

SUBROUTINES: None

DESCRIPTION:

This subroutine may be used in two ways: To retrieve one set of standard deviations and biases for a specific sensor or for the next sequential sensor. To retrieve a set for a specific sensor, use call sequence (3); no initialization is required. If retrieving a set for sequential sensors, it is necessary to "JMP INITSIG" only before the first use of call sequence (2). INITSIG sets the beginning address of SGBLOC. With every call of SIGGET (Call sequence 2) this address is modified to retrieve the next set of deviations and biases. The maximum number of sets is 100.
PURPOSE: To convert a Simulation Parameter Card into IBLOC format.

CALL SEQUENCE: TMA (WORD)
               JMP SPARM
               JAZ (ERROR)

INPUTS: WORD = C/HLT, (Card address); C/HLT, (Block address)

OUTPUTS: ERROR = Error on conversion
         One set of simulation parameters entered in IBLOC - see IBLOC format.

STORAGE REQUIREMENTS: 93 Cells

SUBROUTINES: Common: CARDER, SFXFLTA, SFXFLTA

DESCRIPTION:

The subroutine converts a Simulation Parameter Card into IBLOC format. If an error is found, the card will be rejected with an error comment; the normal exit will be taken with the A Reg = 0.
PURPOSE: To output results of a distribution of the delta classical elements.

CALL SEQUENCE: JMP SPOUT 1

INPUTS: VQ Table (from STOB)
         HBLOC (from STOB)
         STCOUNT (counter in STOB)

OUTPUTS: Label
         S1, S2, NS, I
         σ, μ, e_min, e_max, Δ_e, e_o
         Histogram

STORAGE REQUIREMENTS: 222 Cells

SUBROUTINES: Common: PANT, GLOP, PAGECON
              Program: FDOUT

DESCRIPTION:

This is a subroutine used by STOB to output the results of a distribution of the delta classical elements. If C is not corrected, it will not be processed by STOB and SPOUT 1 will print a comment. FDOUT is a program subroutine to output the histogram; it is also used by SPOUT 2.
PURPOSE: To output results of a distribution of the delta position and velocity elements.

CALL SEQUENCE: JMP SPOUT2

INPUTS: 
- OPOUT1
- OPOUT2
- VQ Table (See STOB)
- HBLOC (See STOB)
- OCOUNT, STCOUNT (Counters in STOB)
- CASETYP (From ERP)
- UNITEST (See Description)

OUTPUTS: This subroutine has several output options:

1. CASETYP ≠ 2
   - OPOUT1 = 0, Print label epoch, min. since epoch, µ, σ, e_min, e_max
   - OPOUT1 ≠ 0, Print label epoch, min. since epoch, µ, σ, e_min, e_max, histogram.
   - OPOUT2 = 0, Punch label epoch, min. since epoch µ, σ, e_min, e_max
   - OPOUT2 ≠ 0, None

2. CASETYP = 2 (Quad. Analysis)
   - STPBLOC will be built, while
   - OPOUT2 will be tested but OPOUT1 will be bypassed when
     STPBLOC is built. Label, µ, σ, e_min, e_max will be printed.

STORAGE REQUIREMENTS: 161 Cells

SUBROUTINES: Common: PANT, GLOP, PAGECON, SPOUT1
- Program: STVQ, VQPUNCH, FDOUT (See SPOUT1), STOUT3

DESCRIPTION:

This is a subroutine to be used by STOB to output the results of a distribution of the delta position and velocity elements.

When this subroutine is used by STOB, STOB will expect
- UNITEST = 0/5T15 for DPVBLLOC
- 0/15T15 for STPBLOC

as additional input.
PURPOSE: To issue a single tab or double tab to the flexowriter.

CALL SEQUENCE:

(1) For single tab:
   JMP STAB

(2) For double tab:
   JMP DBLTAB

INPUTS: None

OUTPUTS: Tab characters transmitted to the flexowriter.

STORAGE REQUIREMENTS: 4 Cells

SUBROUTINES: None
PURPOSE: To convert a standard deviation and bias card (M card) into SGBLOC format.

CALL SEQUENCE:
TMA (WORD)
JMF STDEV
JAZ (ERROR)

INPUTS: WORD = C/HLT (Card address); C/HLT, (Block address)

OUTPUTS: ERROR = Error on conversion
One set of standard deviations and biases entered in SGBLOC

STORAGE REQUIREMENTS: 45 Cells

SUBROUTINES: Common: SFXFLTA, CARDER

DESCRIPTION:
This subroutine converts an M card into SGBLOC format. If an error is found, the card will be rejected with an error comment; the normal exit will be taken with the A Reg = 0.
PURPOSE: To retrieve three astrodynamical constants which vary with the year.

CALL SEQUENCE: TMQ \[\text{REFYEAR}\] JMP STLC

INPUTS: \text{REFYEAR} = 0000000Y, Y = Significant year digit in BCD Option: 0000NNNN, N = Full year, with program extracting the year digit

OUTPUTS: THGRO = \theta (Radians) XLSUNO = L^0 (Radians) C3 = -\theta_3 (Radians)

STORAGE REQUIREMENTS: 44 Cells

SUBROUTINES: None

DESCRIPTION: This subroutine is only usable for the years 1957 - 1966, as it interprets only the last digit to retrieve the constants, i.e., 8 \rightarrow 1958, 1 \rightarrow 1961.
PURPOSE: To statistically process any sample size of a set of variant quantities.

CALL SEQUENCE: TIJ (WORD) TJM ST11 JMP STOB

INPUTS:
- WORD = Name of output routine
- OCOUNT = 00000000 (Counter)
- TEST NS - If NS > N, make NS = N
- VQ table must be filled in as indicated by asterisks (STOB will fill in other values) - See attached format.
- TN = Total no. of sets of quantities (D/T47)
- Table Table
- Block of TN sets of quantities

OUTPUTS:
- \( \mu, \bar{e} \)
- \( \sigma, \bar{e}^2 \)
- \( e_{\text{min}}, \Delta e, e_{\text{max}}, e_0 \), and frequency distribution (HBLOC) also see SPOUT1 and SPOUT2

STORAGE REQUIREMENTS: 377 Cells

SUBROUTINES: Common: SEPSUB, PAGECON, PANT
Program: ST13

DESCRIPTION:

This subroutine processes any sample size of a family of variant quantities and produces a statistic characteristic of the set of quantities. The statistic is given in terms of the mean, standard deviation, minimum, maximum, and frequency distribution.

The label table is a BCD list of names describing the quantities to be processed; BCD names should be centered in the required 3 words/name (This is necessary for printing purposes). Also the names should correspond sequentially to the quantities of the set in the block.

The block format is fixed by sets, i.e., \( (x_1, y_1, z_1, x_2, y_2, z_2, \ldots x_{TN}, y_{TN}, z_{TN}) \). In this example there are \( TN \) sets of quantities which must be in the floating point format.
DESCRIPTION: (continued)

Not all quantities in a set must be processed. \((VQ + 21)\) must be the number of sequential quantities which will be processed. For example, if there are 12 quantities in each set, and the 1st, 2nd, 4th, and 6th are to be processed, the cells would be set as follows:

\[
\begin{align*}
VQ + 18 &= D/12 \ T15 \\
VQ + 21 &= D/6 \ T15 \\
VQ + 24 &= 1/110101 \ T5 
\end{align*}
\]

In such a case, the label table must contain labels describing the 1st 6 entries in the set, although it is desired to suppress the 3rd and 5th quantities. This is necessary because a comment is printed pertaining to the suppressed quantities: (LABEL) - "HISTOGRAM NOT PROCESSED". If all 12 are to be processed, the label table should have 12 labels and the cells would be set as follows:

\[
\begin{align*}
VQ + 18 &= D/12 \ T15 \\
VQ + 21 &= D/12 \ T15 \\
VQ + 24 &= 12/1T11 
\end{align*}
\]

The subroutine will first move the appropriate label to VQ table, and then compute or find the following values:

1. If \(NS = 0\), then \(NS = TN\)
   - If \(I = 0\), then \(I = 1/2 (TN) + 1\)

2. \(\Sigma e, \Sigma e^2\) for \(NS\) quantities
   \[
   \sigma = \sqrt{\frac{1}{NS-1} \sum e^2 - \left(\frac{\Sigma e}{NS}\right)^2}
   \]

3. If \(NS > 1\), then \(\mu = \frac{\Sigma e}{NS}\), \(\sigma^2 = \sum e^2 - \left(\frac{\Sigma e}{NS}\right)^2\)
   - If \(NS = 1\), then \(\mu = \Sigma e, \sigma^2 = 0\)

4. If \(SI \neq 0\), then \(e_o = \mu - S1\sigma\)
   \[
   \Delta e = \frac{(S1 + S2)\sigma}{I}
   \]
   - If \(SI = 0\), then \(e_o = \max \left(\mu - S2 \sigma, 0\right), \Delta e = \frac{\mu + S2\sigma - e_o}{I}\)

5. \(\Sigma e, \Sigma e^2, e\text{min}, e\text{max}\) of \(TN\) quantities

The subroutine will then examine each quantity and determine the cell in the distribution in which it belongs. If the quantity is less than or equal to \(e_o\), it will be considered equal to \(e_o\) and therefore entered in
DESCRIPTION: (continued)

the first cell, otherwise the cell is determined. The integral part of

\[
\frac{e - e_0}{\Delta e} + (0, \text{ if fractional part} = 0) + (1, \text{ if fractional part} \neq 0)
\]

If the result of this equation is greater than I, the quantity will be considered as belonging in the Ith cell. The distribution is located in HBLOC to HBLOC + I - 1, HBLOC + 99 being the maximum. The subroutine will go to the specified output subroutine after each quantity has been processed as none of the results are retained in core. After processing all quantities, the subroutine will exit. SPOUT 1 is the output routine for the DC distribution, and SPOUT 2 for the error prediction distribution.

</table>
PURPOSE: To delete blanks from a BCD word.

CALL SEQUENCE: 
TMQ (WORD)
JMP STRIP
TAM (RESULT)

INPUTS: 
WORD = 8 characters possibly containing blanks
(example: \(\Delta T \triangle ES \triangle TA\)

OUTPUTS: 
RESULT = Word, all blanks removed, right justified with leading zeros.
(Example: 0000 TEST)

STORAGE REQUIREMENTS: Part of SYS

SUBROUTINES: None
PURPOSE: To aid in processing input cards

CALL SEQUENCE: TMA (WORD)
JMP SXSRCH
JAZ (ERROR)

INPUTS: WORD = C/HLT, 0; C/HLT, (Address of format word list)
See description for format word list.

OUTPUTS: See Description

STORAGE REQUIREMENTS: 91 Cells

SUBROUTINES: Common: CARDERB, PAGECON, SFXINT, SFXFLT, PANT.

DESCRIPTION:

The format word list is a set of parameters used to unpack, convert, and store specified fields (max. - 16 col) on input cards. A format word has the form:

C/(Command 1), (Address 1); C/(Command 2), (Address 2)

Command 1 = { HLT, if alphanumeric conversion desired
               JBT, if fixed integer conversion desired
               ICOZ, if floating point conversion desired

Address 1 = P * 128 + F, P = last column in field, 0 < P < 80
           F = no. of columns in field, 0 < F < 16

Command 2 = { TMA, for all format words except the last
              CAM, if last format word in list

Address 2 = Location in which converted field is to be stored

Alphanumeric conversion leaves data right justified, preceded by blanks. If F ≤ 8, only one word will be stored in Address 2. If F > 8, two words will be stored in Address 2 and Address 2 + 1.

Fixed Integer Conversion leaves a fixed binary integer 747 in Address 2. The conversion will terminate on a decimal point, therefore ▲ ▲ ▲ 75.62, ▲ ▲ ▲ 75.0, and ▲ ▲ ▲ ▲ ▲ 75 will all convert as D/75.

Proceeding + or - signs are allowed.
DESCRIPTION: (continued)

Floating point Conversion leaves a floating point number in Address 2 with one exception: If the field specified is all blanks, Address 2 will contain OCTAL 0. Input can be any of the following formats.

+XXXX.XXX  
+XXXXXXX  
+XX.XXXX+XXX  
+XXX.XXXE+XXX

All preceding, imbedded, and following blanks will be suppressed in both fixed and floating conversion. Preceding zeros will also be suppressed. Therefore, 0 + 10 will convert as D/10 or F/10. Depending on the type of conversion specified.

If an error occurs on any field, SXSRCH will print the diagnostics before returning control. The entire card is always converted.
PURPOSE: To convert a pair of variant element cards into VEBLOC format.

CALL SEQUENCE: TMA (WORD1)
                TMQ (WORD2)
                JMP VECARD
                JAZ (ERROR)

INPUTS:  WORD1 = C/HLT, (Card 1 address); C/HLT, 0
         WORD2 = C/HLT, DEBLOC; C/HLT, VEBLOC

OUTPUTS:  ERROR = Error on conversion
          One set of N M elements in VEBLOC
          One set of classical elements in DEBLOC

STORAGE REQUIREMENTS:  56 Cells

SUBROUTINES:  Common: ELMRED, ELEM1, ELEM2, ETYPA, ETYPB, ARCTAN,
               ARCCOS

DESCRIPTION:

The subroutine will unpack cards 1 and 2; if an error occurs a comment will be printed and the normal exit will be taken with the A Reg = 0. Having unpacked the cards, the subroutine checks the element type to see that it is either A or B; if not, the above error procedure is followed. The input elements are converted to N M elements and stored in VEBLOC. Corresponding classical elements are stored in DEBLOC; these will be used later to create a true delta element block (DEBLOC). The maximum number of sets of elements in VEBLOC and DEBLOC is 100.
PURPOSE: To retrieve next control line

CALL SEQUENCE: JMP 1NXTCON

INPUTS: Magnetic tape, paper tape, or flexowriter
CONBITS

OUTPUTS: See Description

STORAGE REQUIREMENTS: Part of SYS

SUBROUTINES: None

DESCRIPTION:

This subroutine puts the next control line from the
flexowriter, paper tape, or magnetic tape into core locations CONLINE
through CONLINE + 9.

1. Magnetic tape - Blank cards are ignored
2. Flexowriter - First parameter CONLINE + 1 (Left Justified)
   Second parameter CONLINE + 2 (Left Justified)
   Etc.
3. Paper tape - Same as Flexowriter

1NXTCON uses bits 1-15, 21-23, 42-47 of "CONBITS", therefore the user
program must insure that "CONBITS" is properly set for its purposes.
PURPOSE: To transmit information to the flexowriter.

CALL SEQUENCE: TMA (WORD)
                 JMP 1TPOUT

INPUTS: WORD = C/HLT, (Beginning address of comment); C/HLT, (No. of words)

OUTPUTS: Flexowriter output

STORAGE REQUIREMENTS: Part of SYS

SUBROUTINES: None

DESCRIPTION:

This subroutine will transmit N words to the flexowriter; words of trailing blanks are suppressed. However, it will not issue carriage returns, tabs, upper and lower case shifts.
PURPOSE: To convert BCD numbers to fixed point binary integers.

CALL SEQUENCE: TMA (WORD 1)
TMQ (WORD 2)
JMP SFXINT
JAZ (ERROR)
TQM (RESULT)

INPUTS: WORD 1 16 character BCD number
        WORD 2

OUTPUTS: RESULT - fixed point binary integer (T 47)

STORAGE REQUIREMENTS: 110 Cells

SUBROUTINES: None

DESCRIPTION:
All blanks are ignored. Only leading zeros are ignored; trailing zeros are significant. The conversion will terminate upon completion of converting 16 BCD characters, or finding a decimal point. If a decimal point is found, the result in the Q register will be the integral part of the number entered. The accumulator will not be zero in this case (i.e. no error).
The data read into the Simulation Error Analysis System and much of the information subsequently generated must be readily accessible to the various parts of the system. For this reason, several blocks of data are defined in high speed core storage. These blocks have been assigned specific formats which are described herein, each under its particular block designation. The formats specify the words as floating point numbers and BCD characters. In general, the BCD characters are six bit characters yielding eight per word. Blank characters are designated by the symbol $\triangle$.

In several instances, the blocks have an associated retrieval routine (see Subroutine Section for details), which will pick a desired entry from the block and place the data in assigned core locations. These assigned locations, which are not necessarily consecutive, and the corresponding retrieval routines are included where applicable. There are a few blocks which have no retrieval routines as such, but which have assigned storage locations where the associated quantities may be placed by the user. Other blocks have assigned storage locations with the block itself, and may be referred to directly by these assignments.

Figure 6-1 displays the storage assignments for all of the core block reservations. Storage assignments are also shown for the other system components.

O = Control Character, O = Observation Type, N = Sensor Number
+1
+2 ρ = Range (Earth radii)
+3 A, α = Azimuth or Right Ascension (Rad)
+4 h, δ = Elevation or Declination (Rad)
+5 \( \dot{\rho} \) = Range rate (Earth radii/\( k_e \) min)

Data block is variable in length, but must be ended with a word of zeros.

BLOCK GENERATION: COBLOC is generated in the MOCARO unit. It also may be generated for sequences which read in observation cards. In these cases, COBLOC is generated by the OCCARD subroutine for system observation cards or by the COBCRD subroutine for SPADATS observation cards.
BLOCK RETRIEVAL: Entries in COBLOC can be retrieved sequentially or by sensor number by the COBGET subroutine. An entry to INITCOB is required in order to initialize COBGET for the first COBLOC entry. Each reference to COBGET will retrieve the next COBLOC observation entry if the sensor number is not specified, placing the data in the following core locations and word formats:

| A | A | A | A | N | N | N
|---|---|---|---|---|---|---
| 0 | 0 | 0 | 0 | 0 | 0 | ooxx xxx

- 48 bit floating point

<tr>
<td>to a maximum of 700 core locations (100 sets)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Data block is variable in length but must be ended with a word of zeros.

BLOCK GENERATION: DEBLOC is generated internally by the SGPDC unit. In SEA8 it is generated by the PREERP program which controls the reading of Element and Variant Element cards. In both cases the values are the result of variant elements minus nominal elements.
BLOCK RETRIEVAL: Entries in DEBLOC are retrieved sequentially by the DELGET subroutine. An entry to INITDEL is necessary to initialize DELGET to begin with the first set of delta elements. Each entry to DELGET will retrieve the next set of data and place it in the following core locations and word formats:

<table>
<thead>
<tr>
<th>48 bit floating point</th>
<th>DELA</th>
<th>$\Delta a$ (Earth radii)</th>
</tr>
</thead>

EBLOC

- **E** = Control Character, **T** = Element Type
- **A** = Element Number, **N** = Satellite Number

+0  \( E \) = Control Character, \( T \) = Element Type
+1  \( a_{x_{No}} \)
+2  \( a_{y_{No}} \)
+3  \( h_{xo} \) \((\text{Earth radii})^2 \) \( k_{e}^{-1} \text{min} \)
+4  \( h_{yo} \) \((\text{Earth radii})^2 \) \( k_{e}^{-1} \text{min} \)
+5  \( h_{zo} \) \((\text{Earth radii})^2 \) \( k_{e}^{-1} \text{min} \)
+6  \( L_{o} \) (Radians)
+7  \( C_{o} \) (Days/Rev^2)
+8  \( t_{o} \) = Time from beginning of year to epoch (Days)
+9  \( \theta_{to} \) = Greenwich Sidereal time at epoch (Radians)
+10 \( \text{YYYYDDHH} \) Epoch (blank if element type C, D)
+11 M M S S · SSS

Data block is fixed length (13 words)

BLOCK GENERATION: EBLOC is generated in the EXEC unit by the ELMRED subroutine. Element cards 1 and 2 are interpreted and converted to N M elements, \( t_{o} \) and \( \theta_{to} \) are computed, and EPOCH time is transferred from Element Card 2 to this block. Only one set of elements is allowable for each job.
BLOCK RETRIEVAL: Entries in EBLOC are retrieved by the EUNPCK subroutine. Since there is one set of elements, initialization of the routine is unnecessary. This routine places the data in the following core locations:

<table>
<thead>
<tr>
<th>SATN</th>
<th>Satellite Number</th>
</tr>
</thead>
<tbody>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Data block is variable in length but must be ended with a word of zeros.

**BLOCK GENERATION:** IBLOC is generated in the EXEC unit by subroutine ICARD. All of the quantities are input on Simulation Parameter cards (I cards).

- **I** = Control Character, **V** = V Type, **O** = O Type, **N** = Sensor Number
- **h_i** = Initial elevation (Radians)
- **h_f** = Final elevation (Radians)
- **ρ_{max}** = Maximum range (Earth radii)
- **Δt** = Observation interval (Minutes)
- **X** = Segments to use (4 Bit BCD)
- **N** = Number of segments
Entries in IBLOC are retrieved by sensor number by the subroutine IGET. An entry to INITI is required once to initialize counters and addresses. Each reference to IGET will retrieve the data corresponding to the specified sensor and place it in the following core locations and word formats:

<table>
<thead>
<tr>
<th>△</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Data block is variable in length but must be ended with a word of zeros.

BLOCK GENERATION: SBLOC is generated in the EXEC unit by the SENCARD subroutine. All the quantities are input on Sensor cards (S cards) except for Z and \( X/\cos \theta \) which are computed.
BLOCK RETRIEVAL: Entries in SBLOC can be retrieved sequentially or by sensor number by the SENGET subroutine. An entry to INITSEN is required to initialize SENGET to begin with the first sensor. The sensor number will be placed in STAID only if sequential retrieval is used. Each reference to SENGET will retrieve the data for the next sensor or the specified sensor and place it in the following core locations and word formats:

<table>
<thead>
<tr>
<th>48 bit floating point</th>

|                     | (Days/Rev$^2$) |
The card formats compatible with the Simulation Error Analysis System fall into three main categories: SYS cards, SEA cards, and Data cards. SYS cards are designed to be used by SYS and are processed by SYS. SEA cards are designed for the SEA System and are processed by the SEA EXEC. The Data cards are designed to provide input data to the SEA System and are also processed by the SEA EXEC.

SYS Cards

The card function of SYS cards is given in Columns 17-24. The following SYS cards are allowed during an SEA run (reference should be made to Philco SYS documentation for interpretation and format details):

- DUMP
- SNAP
- OCT
- COMMAND
- JMP
- JMPL
- JMPR
- CONIN
- HLT
- REM
- IBIT
- ORIGIN
- COMMON
- MASTER
- REWIND
- REWINDLO
- LOCSENT
- WRTSENT
- READF
- READB
- WRITE
- CLOCK

SEA Cards

The card function for SEA cards is given in Columns 17-24. The SEA cards defined to date are:
**Data Cards**

The function of Data card is indicated by a "card type" in Column 80. This card type is one BCD letter assigned to that card. Data cards defined to date include:

<table>
<thead>
<tr>
<th>Name</th>
<th>Card Type</th>
<th>Figure</th>
</tr>
</thead>
<tbody>
<tr>
<td>SENSOR</td>
<td>S</td>
<td>7-6</td>
</tr>

</tbody>
</table>

In the card figures, the letters appearing at the top of a column in the fields of the card image, have the following meanings:

- **A** - Entry in this field consists of letters and in general form, a word for identification purposes
- **F** - Entry in this field will be interpreted as a floating point number
- **I** - Entry in this field will be interpreted as a fixed point integer
- **O** - Entry in this field will be interpreted as octal format.

SYS CARD
The core location assignments which are common to all of the program units in the Simulation Error Analysis System are defined in the following list. Common block storage assignments are included in the dictionary with their associated lengths and numbers of sets of data specified. The system constants are grouped together, their numerical values being included in the definition.
SIMULATION ERROR ANALYSIS DICTIONARY

A  SEMI-MAJOR AXIS
ADOTU  DOT PRODUCT OF A, D, OR L BAR WITH U BAR
ADOTV  DOT PRODUCT OF A, D, OR L BAR WITH V BAR
ADOTW  DOT PRODUCT OF A, D, OR L BAR WITH W BAR
ALPHA  RT ASCENSION OR AZIMUTH OF OBJ
ALSUN  RIGHT ASCENSION OF THE SUN AT TIME T
AO  A SUB O,SERMI-MAJOR AXIS AT EPOCH
APMFLAG  DEFINES ERROR PREDICTION COMPUTATIONAL METHOD
AR  A/R ,A=SEMI-MAJOR AXIS ,R=RADIUS VECTOR
ASUBX  X COMP OF A BAR OR A BAR TILDE, UNIT VECTOR PERPENDICULAR TO L BAR
ASUBY  Y COMP OF A BAR OR A BAR TILDE, UNIT VECTOR PERPENDICULAR TO L BAR
ASUBZ  Z COMP OF A BAR OR A BAR TILDE, UNIT VECTOR PERPENDICULAR TO L BAR
ASUXT  A SUB XHO, X COMP WITH RESPECT TO HORIZON SYSTEM OF A BAR TILDE
ASUYT  A SUB YHO, Y COMP WITH RESPECT TO HORIZON SYSTEM OF A BAR TILDE
ASUZT  A SUB ZHO, Z COMP WITH RESPECT TO HORIZON SYSTEM OF A BAR TILDE
AX  X COMPONENT OF VECTOR TO PERIGEE WITH MAG E
AXN  A SUB XN=E*COS OMEGA ,X COMP OF A BAR=E*P BAR IN ORBIT PLANE
AXNO  A SUB XN SUB O=E*COS OMEGA ,X COMP OF A BAR IN EPOCH ORBIT PLANE
AY  Y COMPONENT OF VECTOR TO PERIGEE WITH MAG E
AYN  A SUB YN=E*SIN OMEGA ,Y COMP OF A BAR=E*P BAR IN ORBIT PLANE
AYNO  A SUB YN SUB O=E*SIN OMEGA ,Y COMP OF A BAR IN EPOCH ORBIT PLANE
AZ  Z COMPONENT OF VECTOR TO PERIGEE WITH MAG E
BETA  ANGLE BETWEEN ORBITAL PLANE AND PLANE OF THE OBJ AS OBSERVED
BIASALP  BIAS ALPHA IN RAD.  (EITHER RIGHT ASCENSION OR AZIMUTH)
BIASDLT  BIAS DELTA IN RAD.  (EITHER DECLINATION OR ELEVATION)
BIASRHO  BIAS RANGE IN ER
BIASRRI  BIAS RANGE RATE IN ER/KEMIN
C  C DOUBLE PRIME=1/2*DN/DT  *A DRAG COEFF
CAPPF  DEFINES ERROR PREDICTION FINAL PREDICTION POINT
CAPPI  DEFINES ERROR PREDICTION INITIAL PREDICTION POINT
CAPR  MAGNITUDE OF INERTIAL VECTOR FROM STATION
CAPX  X COMP OF CAPITAL R BAR =STATION VECTOR
CAPY  Y COMP OF CAPITAL R BAR =STATION VECTOR
CAP2  Z COMP OF CAPITAL R BAR = STATION VECTOR
CAMS  INDICATION OF DATA CARDS FOUND
CCARD  INDICATION OF CONTROL CARDS FOUND
CASETP  DEFINES ERROR PREDICTION POINTS
C0  C SUB 0 = 1/2*CP/CN * A DRAG COEFF
COHLOC  CONTAMINATED OBSERVATION BUFFER, 3001 CELLS (500*6 WORD ENTRIES + 1
WORD)
ICHARCT  NO. OF CHAR. IN LAST VARIABLE FIELD PARAMETER, FIX INTEGER TIS.
COBSTB  RIGHT ADDRESS = CURRENT LOCATION BEING USED IN COBLOC
CONBITS  SYS MASTER CONTROL SWITCH
CONLINE  10 WORD INPUT CARD IMAGE BUFFER IN SYS
COCOUNT  RIGHT ADDRESS = NUMBER OF 6 WORD ENTRIES IN COBLOC
COSOE  COS(E+OMEGA), E = ECCENTRIC ANOM, OMEGA = ARG OF PERIFOCUS
COSI  COS I, I = INCLINATION
COSO  COS NODE = N SUB X
COSOM  COS OMEGA, COSINE OF ARG OF PERIFOCUS
COSPH  COS LATITUDE
COSPHS  COSINE OF PHI SUB S, GEOCENTRIC LATITUDE OF SUB-SATELLITE POINT
COSTH  COS THETA, THE SIDEREAL TIME
COSU  COS ARG OF LATITUDE
COSVO  COS TRUE ANOMALY AT EPOCH
CSALS  COSINE OF RT. ASCEN. OF SUN AT TIME T
CSDLS  COSINE OF DECLINATION OF THE SUN AT TIME T
CXDOT  X COMP OF CAP R BAR DOT (STATION VELOCITY VECTOR)(RAD/KEMIN)
CYDOT  Y COMP OF CAP R BAR DOT (STATION VELOCITY VECTOR)(RAD/KEMIN)
CZDOT  Z COMP OF CAP R BAR DOT (STATION VELOCITY VECTOR)(RAD/KEMIN)
CIT  CIT
C3  CORRECTIVE QUANTITY, USED IN COMPUTING TRUE LONGITUDE OF SUN
DCCP1  DC CONTROL FOR ELEMENT CORRECTION SPECIFICATION
DCCP10  DC CONTROL FOR DISTRIBUTION SUPPRESSION
DCCP2  DC CONTROL FOR NUMBER OF ITERATIONS
DCCP3  DC PERTURBATION CONTROL
DCCP4  DC OUTPUT OPTION CONTROL
DCCP5  DC RMS FACTOR CONTROL
DCCP6  DC CONTROL FOR FIRST ABSOLUTE MAX RANGE AND ANGLE (KM)
DCCP7  DC CONTROL FOR SECOND ABSOLUTE MAX RANGE AND ANGLE (KM)
DCCP8  DC CONTROL FOR ABSOLUTE MAX RANGE RATE (KM/SEC)
DCCP9  DC CONTROL FOR CONVERGENCE CRITERION
DCFIRST  INITIALIZATION SWITCH FOR SGPDC
DCI  I FOR DC DISTRIBUTION (NO. OF CELLS IN DISTRIBUTION)
DCNS  NS FOR DC DISTRIBUTION (NO. OF QUANTITIES TO DEFINE DISTRIBUTION)
DCS1  S1 FOR DC DISTRIBUTION (NO. OF ST. DEV. BELOW THE MEAN)
DCS2  S2 FOR DC DISTRIBUTION (NO. OF ST. DEV. ABOVE THE MEAN)
DEBLOC  DELTA ELEMENT BUFFER, 701 CELLS (100*7 WORD ENTRIES + 1 WORD)
DECOUNT  RIGHT ADDRESS = NUMBER OF 7 WORD ENTRIES IN DEBLOC
DELA  SAME AS DELA0
DELA0  TOTAL CORRECTION IN SEMI-MAJOR AXIS AT EPOCH
DELCAPP  DEFINES INTERVAL BETWEEN ERROR PREDICTIONS
DELC0  TOTAL CORRECTION IN DRAG PARAMETER AT EPOCH
DELE  SAME AS DELE0
DELE0  TOTAL CORRECTION IN ECCENTRICITY AT EPOCH
DEL1  SAME AS DEL10
DEL10  TOTAL CORRECTION IN INCLINATION AT EPOCH
DELM0  TOTAL CORRECTION IN MEAN ANOMALY AT EPOCH
DELMOD  SAME AS DELM0
DELM00  TOTAL CORRECTION IN LONGITUDE OF NODE AT EPOCH
DELOM  SAME AS DELOM0
DELOM0  TOTAL CORRECTION IN ARG OF PERIGEE AT EPOCH
DELSB  RIGHT ADDRESS = CURRENT LOCATION BEING USED IN DEBLOC
DELT  DECLINATION OR ELEVATION OF OBJ
DELTX  X COMP OF DELTA L BAR = L BAR OBS - L BAR COMPUTED
DELTY  Y COMP OF DELTA L BAR = L BAR OBS - L BAR COMPUTED
DELTZ  Z COMP OF DELTA L BAR = L BAR OBS - L BAR COMPUTED
DENC  ((1+1-E**2)**1/2)**2 * (1-E**2)**1/2, E = ECCENTRICITY
DIRF  DEFINES ANTI OR POST MERIDIAN POSITION OF HF
DIRI  DEFINES ANTI OR POST MERIDIAN POSITION OF HI
DLSUN  DECLINATION OF SUN AT TIME T
DPCCOUNT  RIGHT ADDRESS = NUMBER OF 8 WORD ENTRIES IN DPVBLOC
DOL  BCD DOLLAR SIGN TH7, LEADING ZEROS.
DPVBLOC  DELTA POS-VEL BUFFER, 801 CELLS (100*8 WORD ENTRIES + 1 WORD)
DPVF0  DEFINES ERROR PREDICTION OUTPUT
DPVSTB  RIGHT ADDRESS = CURRENT LOCATION BEING USED IN DPVBLOC

In order to provide test data for system checking, and also to illustrate a few of the possible output options, the documentation incorporates two test cases. The output for these two cases is presented here in the actual computer output format. Complete input for these cases is also provided so that the runs may be duplicated for the above mentioned system check. The input cards are described by fields, omitting fields that are blank for these cases. Reference should be made to System Card Formats for identification of the fields on each card.

9.1 TEST CASE 1

The first test case, EXAMPLE SEAL A ELEMENTS POINTS ANALYSIS, was run on SEAL with type A elements as input. Acquisition times were generated for three sensors, each having a different maximum range, for a duration of 112 minutes. Observations were simulated and differentially corrected with no perturbations. The SGPDC unit was executed with no overrides. ERPRED predicted position and velocity errors at the end of the third and at the end of the fourth revolutions, and also generated the statistical output at these points.

The input cards for this Sequence 1 run include all those shown in Figure 2-9. The contents of the cards are as follows:

FNM JOB EXAMPLE SEA1 AELEMENTS: POINT ANALYSIS

SYS027FC 11-02 10:36.1 11-02 10:36.8
9.2 TEST CASE 2

The second test case, EXAMPLE SEA1, C ELEMENTS, QUADRANT ANALYSIS, was run on SEA1 with type C elements as input. This type restricts the simulation to a single sensor. Acquisition times were generated for this sensor with a maximum range of 10,000 km. for a duration of 992 minutes. The acquisition times were not printed according to the output option. Observations were generated and differentially corrected with perturbations. Only the first observation in each time segment was printed as specified, while no results of the MOCARO and the SGPDC units were printed.

The error predictions were computed for 40 equally spaced points in each of four quadrants beginning at the time of the last observation. The statistical analysis of this data over each quadrant was then used to generate the error trend in each component of position and velocity for each quadrant. Only the trends over the first quadrant are displayed in the output in order to conserve space.

Since this case is also a Sequence 1 run, its input cards also conform with the set shown in Figure 2-9. The contents of the cards are as follows:
