Thermodynamic equations characterizing the chemical stability of heteronuclear diatomic molecules AB are presented. These equations permit one to predict the conditions in which yet unknown molecules can be observed. The chemical stability of the transition element (over)

chalcogenides is discussed.

A similarity in trend of the heat of vaporization of transition elements, the lattice energy and the dissociation energy of their chalcogenides is pointed out. AB molecules can be classified in groups for which the value of the ratio

\[ \frac{A_{AB}^{\text{Lattice}} - A_{AB}^{\text{Solid}}}{D_{AB}} \]

is characteristic. This parameter is important for predicting the chemical stability and available values are reviewed.
Thermodynamic equations characterizing the chemical stability of heteronuclear diatomic molecules AB are presented. These equations permit one to predict the conditions in which yet unknown molecules can be observed. The chemical stability of the transition element chalcogenides is discussed.

A similarity in trend of the heat of vaporization of transition elements, the lattice energy and the dissociation energy of their chalcogenides is pointed out. AB molecules can be classified in groups for which the value of the ratio

is characteristic. This parameter is important for predicting the chemical stability and available values are reviewed.
FOREWORD

This report was prepared by the University of Brussels, Belgium, under USAF Contract No. AF61(052)-225. The contract was initiated under Project No. 7350, "Refractory Inorganic Non-Metallic Materials," Task No. 735001, "Non-graphitic." The work was administered under the direction of the Air Force Materials Laboratory, Deputy Commander/Research and Engineering, Aeronautical Systems Division, Wright-Patterson Air Force Base, Ohio. Mr. F. W. Vahldiek was the project engineer.

This report covers work done from April 1962 to April 1963.
Thermodynamic equations characterizing the chemical stability of heteronuclear diatomic molecules AB are presented. These equations permit one to predict the conditions in which yet unknown molecules can be observed. The chemical stability of the transition element chalcogenides is discussed.

A similarity in trend of the heat of vaporization of transition elements, the lattice energy and the dissociation energy of their chalcogenides is pointed out. AB molecules can be classified in groups for which the value of the ratio

\[ \alpha = \frac{\Delta H^\circ[\text{st.} \text{AB solid}]}{D^\circ (\text{AE})} \]

is characteristic. This parameter is important for predicting the chemical stability and available values are reviewed.

This technical documentary report has been reviewed and is approved.

**INTRODUCTION**

The object of the present paper is to extend to heteronuclear diatomic molecules, symbolized by AB, considerations previously given for homonuclear diatomic molecules $M_2$\(^{(1)}\). In addition to the usual concept of the stability of a given diatomic molecule, i.e., its dissociation energy, which is a measure of the bond strength of this molecule and which was called the "physical stability", a "chemical stability" was defined which is related to the possibility of observing this molecule. For homonuclear diatomic molecules, the chemical stability was defined as a free energy change which gives a measure of the relative concentration of diatomic to monoatomic species in thermodynamic equilibrium with the solid or liquid phase. This chemical stability was shown to depend on the parameter

$$a = \frac{\Delta H^0_{\text{vap.}M}}{D^0_0(M_2)},$$

which was correlated with the electronic structure of the ground state of the free atom and the atomic number; $\Delta H^0_{\text{vap.}M}$ is the heat of vaporization of the monoatomic species and $D^0_0(M_2)$ the dissociation energy of the diatomic molecule. Further, for the transition elements a correlation was given between $\Delta H^0_{\text{vap.}M}$ and the excitation energy of the free atom to well defined low lying electronic states\(^{(1,2)}\).

In this paper, the chemical stability of AB molecules will be defined and again special focus will be put...
on certain molecules of the transition elements. It has been pointed out by Krikorian(3) that the bonding energies of solid carbides, silicides, nitrides and oxides of the transition elements follow a trend similar to that of the heats of vaporization of the elements. It is shown here that this is also the case for gaseous monoxides of the transition elements. Finally a parameter \( \alpha = \frac{\Delta H^0(\text{at.AB})}{D^0(\text{AB})} \) similar to the one defined previously for homonuclear diatomic molecules appears to be important for the classification of the chemical stability of \( \text{AB} \) molecules; \( \Delta H^0(\text{at.AB}) \) is the energy required to transform one half molecule gram of solid \( \text{AB} \) compound into atoms and \( D^0(\text{AB}) \) the dissociation energy of the gaseous \( \text{AB} \) molecule. The available \( \alpha \) values are reviewed.

**THE CHEMICAL STABILITY OF AB MOLECULES.**

In the case of homonuclear diatomic molecules, the highest concentration of \( \text{M}_2 \) molecules relative to \( \text{M} \) atoms is obtained in the saturated vapor. It was therefore proposed to define the "chemical stability" of \( \text{M}_2 \) molecules as the free energy change \( \Delta G^0_T \) corresponding to the equilibrium

\[
\text{M} + (\text{M}) \rightleftharpoons \text{M}_2
\]

\[
\Delta G^0_T = -RT \ln \left( \frac{p(\text{M})}{p(\text{M}_2)} \right) = D^0(\text{M}_2) - \Delta H^0_0(\text{vap.M}) - T \Delta \left( -G^0_T - H^0/T \right)
\]

\[
= \Delta H^0_0(\text{vap.M}) \left( 1 - \frac{1}{\alpha} \right) - T \Delta \left( -G^0_T - H^0/T \right)
\]
Square bracketts [ ] denote the condensed phase, symbols without bracketts are used for gaseous species. In a similar manner it is now proposed that the chemical stability of a heteronuclear diatomic molecule be defined as some measure of the concentration of AB molecules above condensed ([AB] relative to the most abundant of the other gaseous species. Therefore its definition will depend on the vaporization process of (AB). In addition to the process leading to AB molecules

\[(\text{AB}) \rightarrow \text{AB} \quad (0)\]

four other processes will be considered

\[(\text{AB}) \rightarrow \text{A} + \text{B} \quad (1)\]
\[(\text{AB}) \rightarrow (\text{A}) + \text{B} \quad (2)\]
\[(\text{AB}) \rightarrow \text{A} + 1/2 \text{B}_2 \quad (3)\]
\[(\text{AB}) \rightarrow (\text{A}) + 1/2 \text{B}_2 \quad (4)\]

Besides these four processes a comprehensive list should comprise numerous other modes of vaporization such as the formation of stoichiometric or non-stoichiometric solid compounds \(A_xB_y\), solutions or alloys; solids and liquids should be distinguished; higher polymeric species than \(B_2\) and AB as well as gaseous molecules \(A_xB_y\) should also be considered. The detailed discussion of these cases will not be given as the relevant equations may be found easily using the same principles as applied here.

For the simplest decomposition process (process(1)), the chemical stability of AB is obtained by combining reactions
(0) and (1) yielding the evaporation equilibrium

$$AB \overset{1/2}{\rightarrow} \frac{1}{2}(AB) + \frac{1}{2}A + \frac{1}{2}B$$

for which the free energy change given in Table I is related to the relative abundance of $AB$ molecules and is taken as its chemical stability. A similar treatment of processes (2), (3), and (4) lead to the evaporation equilibria and chemical stabilities given in Table I. As the change in free energy function $-\{(G^0 - H^0)/T\}$ in all the evaporation equilibria is not very considerable, the chemical stability is mainly determined by the enthalpy change (except at very high temperature). Further, Table I (enthalpy conditions) gives the conditions for the predominance of respectively process 2, 3, or 4 compared to process 1, using for the sake of simplicity in the table, again the approximation which consists in neglecting the entropy term. Thus the condition $\Delta H^0(1\rightarrow 2) = \Delta H^0(\text{vap.A}) - \Delta H^0(\text{at.AB}) > 0$ means that process (2) is predominant compared to (1); the condition $\Delta H^0(1\rightarrow 3) = D^0_0(B_2) - \Delta H^0(\text{at.AB}) > 0$, that process (3) is predominant compared to (1), and so forth, or vice versa if the corresponding $\Delta H < 0$. Further due to these conditions, the chemical stability for a given $\Delta H^0(1)$ value is the largest for process (1) and the smallest for process (4).

A distinction, important in practice for heterogeneous equilibria, results from the predominance of the enthalpy terms in $\Delta G^0_T(1)$, (2), (3) and (4). If the corresponding $\Delta H > 0$
high concentrations of A\(\text{B}\) will be found at low temperatures and, as in homogeneous dissociation equilibria, the relative concentration of A\(\text{B}\) will decrease with increasing temperature. For \(\Delta H^0 > 0\) the concentration will be low at low temperature and will increase with temperature, as has already been pointed out for dimers of halides by Brewer\(^4\) and for homonuclear diatomic molecules\(^1\). The former may be called "low temperature molecules", the latter "high temperature molecules". For homonuclear diatomic molecules the distinction appears as \(a < 1\) or \(a > 1\). For heteronuclear molecules in case 1 (Table I), \(\Delta H^0_1 = \Delta H^0_{\text{at. AB}}(1-a)/a\) and the two types of molecules are distinguished in the same manner. For cases 2-4 if \(a > 1\), A\(\text{B}\) is also necessarily a high temperature molecule; \(\Delta H^0_2\) or (3) or (4) may however be smaller than 0 even if \(a < 1\) (\(\Delta H^0_1 > 0\)).

A simple and useful approximation and a satisfactory general picture of the chemical stability, i.e., of the experimental possibilities of observing a given molecule, is obtained from a plot of \(\Delta H^0_{\text{at. AB}}, \Delta H^0_{\text{vap. A}}, D^0(B_2)\) and \(D^0(AB)\) as shown as an example in fig. 1 to 4, for the first row of transition element oxides, sulfides, selenides and tellurides. Of course free energy plots give a more accurate picture and the exact concentration ratios; in that case however sets of plots for each temperature would be necessary.

Since the reduction to 0\(^\circ\)K is uncertain in many
cases the practically equivalent values for 298°K are given. Also the $D^0(AB)$ values even for gaseous oxides are not all as reliable and accurate as would be desired. For the purpose of this paper an estimation of $D^0(AB)$ values for some transition elements chalcogenides was made on the basis of a parallel trend in $D^0$ values for oxides, sulfides, selenides and tellurides.

Where the $\Delta H^0(\text{at.}AB)$ curve in Fig. 1-4 lies above the $\Delta H^0(\text{vap.}AB)$ and $D^0(B_2)$ curve process (1) occurs rather than (2), (3) or (4), and this is, as easily seen, most favorable for observing gaseous AB molecules. Therefore for gaseous oxides of Sc, Ti and V the relative concentrations will be highest; those of Ca, Cr and Mn are considerably less stable partly due to the fact that the dissociation equilibrium of oxygen is shifted towards $O_2$. A relatively favorable situation was expected for CaS and MnS, due to the low value of $\Delta H^0(\text{vap.A})$; this was confirmed by a mass spectrometric study (18). TiS (17) has also been observed. It would be of interest to check the presence of ScS and VS. For the selenides and tellurides, the chemical stability is usually very low. It seems very improbable that the gaseous molecules can be observed with the methods presently available, except perhaps CaSe, CaTe, ScSe, ScTe and MnSe. The gaseous group IV$_B$ - group VI$_B$ molecules are stable (14).

Representation similar to fig.1 to 4 can easily be made for
other groups of compounds. Heats of vaporization are reasonably well known for all elements, as well as the dissociation energies of homonuclear diatomic molecules $B_2$, as far as their presence has to be considered here. Standard heats of formation for many simple compounds are known, making data on $\Delta H^0_{\text{at,AB}}$ available in many cases.

It is also easy to see from such representations that in some instances conditions for studying given types of molecules may be improved by changing the activity of a component by forming an alloy or by maintaining gaseous components at pressures different of the equilibrium decomposition pressure (oxidizing or reducing conditions).

**THE PHYSICAL STABILITY OF TRANSITION ELEMENT OXIDES.**

The similarity in trend of the heat of vaporization of transition elements, of the heat of atomization of the solid $AB$ compounds and the dissociation energies of the gaseous oxides appeared in figs.1 to 4. On the other hand, the highly irregular trend of the heats of vaporization of transition elements especially in the first transition period disappears and a practically smooth curve is obtained$^{(1,2)}$ from Ca to Cu if, instead of the heat of vaporization to atoms in the ground state, the heat of vaporization to a promoted configuration is represented. This promoted configuration includes $d^n$, $d^{n-1}s$ and $d^{n-2}sp$ states where $n$ is the difference between the atomic number $Z$ of the element and the
atomic number of the preceding rare gas. Therefore, it appears that these states play an important part not only in the bonding of the pure elements but also in the solid and gaseous compounds of these elements. It is beyond the scope of this paper to draw further conclusions from this fact. It is believed however that these considerations may form a basis for a more thorough theoretical treatment.

THE RATIO OF HEAT OF ATOMIZATION OF SOLID AND GASEOUS AB COMPOUNDS

It has been mentionned above that the quantity

\[ \alpha = \Delta H_0^0(at.M)/D_0^0(M_2) \]

which appeared to be important parameter for the classification of homonuclear molecules has a parallel for the heteronuclear diatomic AB molecules in the quantity \( \alpha = \Delta H_0^0(at.AB)/D_0^0(AB) \). Here again the values of \( \alpha \) fall into different categories (Table II):

1) The smallest values of \( 0.5 < \alpha < 1 \) are found for the molecules where A and B are a group IV and a group VI or a group III and a group VII elements. These molecules are isosteric with group V homonuclear molecules and the values of \( \alpha \) of these isosteric molecules show a close relationship.

2) It is interesting to note for the typically ionic alkali halides \( \alpha = 0.76 \) is practically constant, although some trends appear. Qualitatively this is easily understood by an ionic model; accurate calculations could of course be made only by solving the well known difficulties about the
exact shape of the "repulsive" interaction. For $I_B$ halides $\alpha$ is somewhat larger but still in general \( \alpha < 1 \).

Thus the molecules isosteric with group V and the ionic molecules are definitely "low temperature molecules". Most other $AB$ molecules seem to have value of $\alpha > 1$. This is the case for the halides $HgX$ for which $\alpha = 1.24; 1.53; 1.95$ and 3.94 is found. For the only known $III_B/V_B$ molecule InSb $\alpha = 1.9$ (for the isosteric $Sn_2$ molecule: $\alpha = 1.5$) and high values of $\alpha$ are the reason why other molecules of this group as well as II/VI could not be observed.

3) again it is interesting to note the values of approximately 1 or more for the transition metal oxides with a smooth increase from TiO and NiO, CuO seems to be a low temperature molecule. However the dissociation energy is uncertain. For the two known transition metal sulfides, the $\alpha$ values are higher than those of the corresponding oxides.

4) an increase in $\alpha$ when going from oxides to sulfides appears also for the $II_A$ molecules for which $\alpha > 1$ with the exception of BaO.

OUTLOOK

The use of the definition of the chemical stability has already facilitated the search for certain previously unknown molecules. In numerous cases reasonably satisfactory predictions can be made as to the possibility and experimental conditions in which such molecules may be found; estimates
of entropies must of course be included. The temperature
dependence of the chemical stability can be foreseen and
as has been shown earlier can be changed systematically if
convenient for the aimed object \(^{(23)}\).

These considerations can also be easily extended
to polyatomic molecules. Dimers or polymers of molecules
can be treated in a similar manner to dimers of elements \(^{(24)}\).

The main point in all these cases is that since
the highest concentrations of gaseous molecules as compared
to dissociation products are observed at the highest pressures,
the chemical stability is defined in the saturated vapor.
At a given temperature therefore, pressure is not an inde-
dependent variable and the chemical stability is given by a
pressure ratio.

Finally, the interesting parallelism between heats
of atomization of solids and dissociation energies of gaseous
molecules as expressed by the \(\alpha\) values are valuable in using
the thermodynamic equations given and may be accessible to
fundamental theoretical considerations. In fact, such regu-
larities exist also for polyatomic molecules and for polymers.
A similarity in trend was observed recently \(^{(26)}\) between the
dissociation energies of the oxides of the lanthanides and
the vaporization energies of the corresponding elements. As
for the transition elements, minima were observed for the
half filled and totally filled \(f\) shell.

\(\Delta \text{H}^{298}\text{(at.AB)}\) values were calculated from heats of formation given by Kubaschewski and Evans(5) and Freeman(13). Heats of vaporization of \(A\) were taken from Part I(1). Dissociation energies and heats of vaporization of \(B_2\) halides were taken from Stull and Sinke(7). The best available value for \(D_2^{298}\text{(AB)}\) were selected from Gaydon(8) and Herzberg(29). Group IV-group VI AB molecules have been reviewed by Colin and Drowart(14).

$$\Delta H_{298}^0(\text{at.\,ASE}) = \frac{1}{2}(-\Delta H_{298}^0(\text{ASE}) + \Delta H_{298}^0(\text{vap.\,A}) + \frac{1}{2}\Delta H_{298}^0(\text{vap.\,Se}_2)$$

$$+ \frac{1}{2}D_{298}^0(\text{Se}_2))$$

$\Delta H_{298}^0$ values were all taken from Kubaschewski and Evans (5) except that of (GeSe) (14); $\Delta H_{298}^0(\text{vap.\,Se}) = 34.1 \pm 1.5$ kcal/mole (7); $D_{298}^0(\text{Se}_2) = 75.4 \pm 2.0$ kcal/mole (20); $D_{298}^0(\text{ZnSe})$ (19); $D_{298}^0(\text{GeSe})$ (14).
Fig. 4 Chemical Stability of Transition Metal Tellurides.

\[ \Delta h_{298}^{0}(\text{at. ATe}) = \frac{1}{2}(-\Delta h_{298}^{0}(\text{ATe}) + \Delta h_{298}^{0}(\text{vap. A}) + \Delta h_{298}^{0}(\text{vap. Te}_2) + \frac{1}{2}D_{298}^{0}(\text{Te}_2)) \]

\[ \Delta h_{298}^{0} \text{ values were all taken from Kubaschewski and Evans}^{(5)} \text{ except that of (GeTe)}^{(14)}; \Delta h_{298}^{0}(\text{vap. Te}_2) = 39.6 \pm 1.5 \text{ kcal/mole}^{(7)}; D_{298}^{0}(\text{Te}_2) = 52.2 \pm 2.0 \text{ kcal/mole}^{(21,22)}; D_{298}^{0}(\text{ZnTe})^{(19)}; D_{298}^{0}(\text{GeTe})^{(14)}. \]

Thermodynamic equations characterizing the chemical stability of heteronuclear diatomic molecules AB are presented. These equations permit one to predict the conditions in which yet unknown molecules can be observed. The chemical stability of the transition element chalcogenides is discussed.

A similarity in trend of the heat of vaporization of transition elements, the lattice energy and the dissociation energy of their chalcogenides is pointed out. AB molecules can be classified in groups for which the value of the ratio

\[ \alpha = \frac{\Delta H^\circ [\text{st.} AB_{\text{solid}}]}{D^\circ (AB)} \]

is characteristic. This parameter is important for predicting the chemical stability and available values are reviewed.
