Government thereby incur no responsibility, nor any obligation whatsoever; and the fact that the Government may have formulated, furnished, or in any way supplied the said drawings, specifications, or other data is not to be regarded by implication or otherwise as in any manner licensing the holder or any other person or corporation, or conveying any rights or permission to manufacture, use or sell any patented invention that may in any way be related thereto.
S U M M A R Y

Growths taken from the hydraulic suction auto-clean strainer of H.M.S. HERMES were found to be a mixed flora of hyphomycetes and ascomycetes; the former was identified as species of Aspergillus while the latter proved to be a sporogenous yeast.

Tests carried out with various concentrations of "Panacide" Sodium showed that a concentration of 1 in 1000 was effective in killing the growths. Recommendations are made for cleaning the system and for adding and maintaining the required concentration of fungicide in the hydraulic fluid.
1. **INTRODUCTION**

A sample of biological growth taken from the forward hydraulic suction auto-clean strainer was received from C.D.L., H.M. Dockyard, Portsmouth, for examination. Subsequently, a visit by a member of H.M.I. staff was made to H.M.S. HERMES and samples of the growth were taken from the miscellaneous hydraulic tank and from the arrrester gear tank. The latter was heavily contaminated with oil.

2. **THE PATENT ORGAN**

On collection, the material consisted of slimy felts of a pale greyish brown colour, which on drying, had a cheese-like consistency. Microscopical examination showed it to be a mixture of the vegetative stages of mycelial fungi and a yeast.

Streak cultures of the material were made on malt-agar and incubated at 25°C for 14 days. Frequent sub-cultures were made and finally pure isolates of the mycelial species were obtained which were identified as *Aspergillus candidus* Link and *Aspergillus flavipes* (Bailey and Soroty) Thoring Church.

*Aspergillus candidus*, when pure, produces pale buff coloured colonies which have paler margins. The mould grows vigorously and quickly forms dense hyphal mat, which soon wetted the riser to the slimy felts found in the auto-clean strainer.

From the hyphal mat, numerous conidiophores arise which bear globose white masses of microscopic spores. These spores are extremely minute and the slightest air current is capable of sweeping them over considerable distances. Fig. 1 shows several fruiting heads of *Aspergillus candidus*, each of which would be capable of producing many thousands of spores. *Aspergillus flavipes* is somewhat similar in appearance but produces columnar heads of spores, particularly in old cultures. The colour of the colony is buff or greyish-buff, often tinted with pink or brown.

The yeast element of the flora is probably a wild saccharomyces and gives the material its sliminess. This organism, shown in Fig. 2, is unicellular and the cells are broadly elliptical, 5-7μ long, 2.5μ wide and usually slightly broader at one end. All yeasts are common in Nature and it would be improbable to determine the origin of the infection. As the yeast constituted a very small proportion of the total bulk of material, its specific determination was not attempted.

3. **EXPERIMENTAL**

Previous research on a similar problem of mould growth in the hydraulic system of H.M.S. CENTUR (I.M., Report No. 104/5(C) December 1963), showed that of the several fungicides examined, "Panacidus" Sodium (sodium salt of 5.5' dichloro 2.2' dihydroxy benzoxazin) was likely to solve the problem. Recommendations were therefore made that "Panacidus" Sodium should be added to the glycerine/water mixture of H.M.S. CENTUR, so that the resultant strength should be about 0.1%. Examination of the system 7 months after the initial addition indicated that this treatment had been successful.

Since, however, the system in H.M.S. CENTUR had been infected with a mixed flora of *Aspergillus* sp., quite different from that found in H.M.S. HERMES, experiments were carried out to determine whether, at that concentration, "Panacidus" Sodium would inhibit growth of the *Aspergillus candidus* yeast flora. /For this
For this purpose, "Panacide" Sodium was added to tubes of glycerine/water hydraulic fluid to give concentrations of 1-10, 1-50, 1-100, 1-200, 1-500, 1-1000, 1-2000, 1-5000, 1-10000 respectively. Six 25 ml replicates of each were prepared. Controls without the addition of "Panacide" were also set up. Spores from a mixed culture of the *A. alternata* conidia/yeast flores were transformed to the surface of 2 cm. diameter cellulose acetate membrane filters and one filter was placed on the surface of the liquid in each tube. The tubes were incubated at 30°C for one month.

Visual observation before the filter membranes were removed from the tubes of hydraulic fluid showed that heavy fungal growth had developed in all tubes containing concentrations of th. "Panacide" Sodium below 1-50 C. (Fig. 3). In the tubes having the higher concentrations of toxic substance the filter membranes were removed and carefully washed free from "Panacide" with sterile distilled water on a sintered glass filter. They were then plated out on petri dishes of maltagar and incubated for 14 days at 30°C.

After 7 days, positive growth was visible on the filters from the tubes containing 1-2000 and 1-5000 "Panacide" Sodium. Filter membranes from the higher concentrations of 1-400 and 1-500 showed no fungal development.

The results after 14 days are shown in Fig. 4, from which it will be seen that the 1 in 1000 concentration prevented mould growth but that the concentration of 1 in 2000 was not sufficiently effective.

4. CONCLUSIONS AND RECOMMENDATIONS

The elimination of the mould will depend upon the thorough cleaning of the whole hydraulic system and the addition of "Panacide" Sodium in sufficient concentration (1-1000) to the glycerine/water fluid.

The tanks, pumps, filter, etc., on such other parts of the system that are accessible should be brushed down with a solution made by adding 3 or 4 oz. of the 40C. solution of "Panacide" Sodium (as supplied by the manufacturer) to 2 gallons of fresh water (1 teacup to 1 bucket of water). When all visible traces of the mould have been removed, the system should be filled with fresh water to which "Panacide" Sodium has been added (6 pints of the 40C. "Panacide" Sodium as supplied to 100 pints of water). The mixture should remain in the system for 2 or 3 days during which time it should be circulated occasionally by operating the pumps. Experience has shown that it is important to remove as much growth as possible so that the chances of re-infection are reduced to the minimum.

The system should then be drained and filled in the usual manner with the 40/60 hydraulic fluid and "Panacide" Sodium to give a 40C. solution; (2 pints of "Panacide" Sodium 40C, as supplied by the makers to 100 gallons is a convenient measure for practical purposes).

Experience in H.V.S. CENTRE has shown that minute traces of mould growth begin to re-appear after 3 or 4 months if less "Panacide" is used. These traces, however, might originate from particles that have become dislodged from inaccessible parts of the system by the operation of the pumps and have escaped the original cleaning down.

In order to eradicate the infection completely it is recommended that the hydraulic fluid, together with the "Panacide" Sodium, should be changed every 3 months or, if this is not convenient, that a further 1 pint of "Panacide" per 100 gallons of hydraulic fluid should be added, if traces of mould are observed.

"Panacide" Sodium is obtainable from Lister, British Drug Houses Ltd., Poole, Dorset.

Record Summary: ADM 249/1535
Title: HMS Hermes: fungal growth in hydraulic system
Availability Open Document, Open Description, Normal Closure before FOI Act: 30 years
Former reference (Department) ACC F87/62
Held by The National Archives, Kew

This document is now available at the National Archives, Kew, Surrey, United Kingdom.

DTIC has checked the National Archives Catalogue website (http://www.nationalarchives.gov.uk) and found the document is available and releasable to the public.

The document has been released under the 30 year rule.
(The vast majority of records selected for permanent preservation are made available to the public when they are 30 years old. This is commonly referred to as the 30 year rule and was established by the Public Records Act of 1967).

This document may be treated as UNLIMITED.
