AP #1.10

## I. Research Program

All of the research problems studied exploited the matrix isolation method as developed at the University of California laboratories. In this method, substances are suspended in solid nitrogen or an inert gas and then studied spectroscopically. The Berkeley laboratory developed this technique with emphasis on the infrared spectral region.

At the time of the initiation of this Air Force support, the matrix isolation technique was practically new. The development of the unique potentialities of the method was significantly aided and accelerated by this financial aid. The work has been fruitful and a new research method has been demonstrated for the detection and study of transient species. Of course, the current importance of the spectroscopic study of high temperature reactions makes this work timely and useful.

Specific novel applications of the method are listed.

### First Infrared Detection of Reactive Species

The detection of HCO is the first definite infrared identification of any triatomic free radical, except for NO<sub>2</sub>, by any technique.

Formyl radical, HCO:	definite (see publication No. 6).
Nitroxyl, HNO	: definite (see publication No. 13).
NH <sub>2</sub> or N <sub>2</sub> H <sub>2</sub>	: identification still doubtful (see publications No. 10, 17).
CH <sub>2</sub>	: identification still doubtful (see publications No. 5, 12).

- iso-diazomethane : identification still doubtful  
(see publications No. 5, 12).
- $N_3$  : identification still doubtful  
(see publication No. 19).

### Chemistry of Reactive Species

The matrix method gives a unique opportunity to study the reactions of free radicals under conditions where secondary reactions are interrupted.

- Hydrogen abstraction by  $CH_3$  : (see publication No. 2)
- Reaction of  $NH$  with  $O_2$  : (see publications No. 3, 15)
- Isomerization of nitrous acid: (see publication No. 3)
- Chemiluminescence of  $C_2H_4$   
formed from  $CH_2$  : (see publication No. 4).

### Primary Act of Photolysis

Because of the inert environment, the primary act of photolysis can be learned in the condensed phases. This is always the crucial reaction in the elucidation of photolysis.

- Methyl iodide and the cage effect: (see publication No. 2)
- Nitromethane : (see publications No. 11, 13)
- Methyl nitrite : (see publication No. 13).

### Hydrogen Bonding

Narrowing of bands of hydrogen bonded polymers gives this method power to segregate the infrared spectra of polymers of different size. No other method permits this.

- Water : (see publication No. 16)
- Methanol : (see publication No. 18)
- Hydrazoic acid : (see publication No. 10).

Formyl Radical, HCO

The detection of HCO by infrared methods has an historic significance. Because of the low absorption coefficients in the infrared, ~~the~~ only two or three diatomic free radicals had been detected earlier (in flames). These were detected mainly because electronic spectroscopy made possible accurate predictions of the absorption frequencies. Diligent search in this laboratory and others for evidence of  $\text{NH}_2$  in flames was indecisive. The matrix isolation method was developed in this laboratory to meet the need for a new approach.

Formyl was produced by photolyzing hydrogen iodide, HI, in solid CO. The identification was verified by detection of both infrared and visible absorption of HCO (see publication No. 6).

Diazomethane,  $\text{CH}_2\text{N}_2$ : A search for  $\text{CH}_2$

On photolysis, diazomethane decomposes to form  $\text{CH}_2$  and the stable  $\text{N}_2$  molecule. It seems to offer a unique opportunity to form  $\text{CH}_2$  under conditions that will permit storage and leisurely spectroscopic study of this interesting molecule. Diazomethane was suspended in  $\text{N}_2$  and in Ar and photolyzed in situ at  $20^\circ\text{K}$ . The products were shown to be distinguishable from the stable products obtained from photolysis of the pure material, either gas or solid. Infrared and visible ultraviolet spectra features were detected which could be assigned to unidentified, presumably unusual molecular species. A thermoluminescent behavior was observed for the first time. Species which could contribute to the spectra include methylene,  $\text{CH}_2$ , and an isomeric form of diazomethane. The thermoluminescence

was assigned to excited  $C_2H_4$  formed on diffusion (see publications, No. 4, 5, and 12).

Nitroxyl, HNO

Both nitromethane and methyl nitrite were photolyzed in solid argon at 20°K. For the first time, methyl nitrite was identified as a photolysis product of nitromethane, both in the matrix and in the gas. Nitroxyl, HNO, was detected in the infrared and identified for the first time (see publications, Nos. 11 and 13).

Hydrazoic acid, HN<sub>3</sub>

Photolysis of HN<sub>3</sub> is expected to produce NH, yet it has never been observed directly. In solid nitrogen, absorptions develop but they are surely not caused by NH. Evidence is considerable that the photolysis produces either NH<sub>2</sub> or N<sub>2</sub>H<sub>2</sub>, though which is not yet clear. Neither species has been definitely identified in the infrared region (see publications, Nos. 10 and 17).

In addition, these experiments and others led to a tentative infrared identification of N<sub>3</sub>. Subsequent work has not provided confirmation of the assignment, though it is generally postulated that a nitrogen atom suspended in solid nitrogen forms some sort of a complex N·N<sub>2</sub> (see publication, No. 19).

Nitrous Acid, HONO

The photolysis of hydrazoic acid, HN<sub>3</sub>, in solid nitrogen containing a small amount of oxygen, produces nitrous acid,

HONO, in both cis and trans forms. This was the first report of this reaction of the radical NH.

It was discovered that near infrared irradiation of the argon suspension of HONO results in a conversion of cis-HONO into trans-HONO. The reaction can be reversed by ultraviolet irradiation. This was the first report of an infrared-induced isomerization. This novel reaction is still under study (see publications, Nos. 3 and 15).

#### Hydrogen abstraction by methyl radicals

The photolysis of  $\text{CH}_3\text{I}$  in solid nitrogen provides a source of methyl radicals with known energy and controlled environment. Various substances have been included in the matrix and quantitative study of the reactions that occur has been carried out. The chemistry of the methyl radicals shows that they react as do methyl radicals at 2000°K. The effect of the matrix cage is examined (see publications, No. 2).

#### II. Personnel

In addition to two faculty personnel, the project has involved the research activities of two post-doctoral students, nine graduate students, and one undergraduate student. The thesis titles of the graduate students who participated are listed.

Faculty personnel

Dr. George C. Pimentel, Professor

Dr. Bruce H. Mahan, Associate Professor

Post-doctoral personnel

Dr. Sydney Leach

Dr. Warren Thompson

Graduate student personnel and present occupation

John D. Baldeschwieler, Instructor, Harvard University.

C. David Bass, Atomics International, Canoga Park, Calif.

George E. Ewing, Jet Propulsion Laboratory, Pasadena,  
Calif.

Harmon W. Brown, Varian Instruments Co., Palo Alto, Calif.

Theodore D. Goldfarb, Assistant Professor, New York State  
University, Oyster Bay, New York.

Ivan Haller, IBM, Poughkeepsie, New York.

James Hanlan, graduate study not completed.

Dolphus E. Milligan, Research Scientist, Mellon Institute,  
Pittsburgh, Pa.

Mathias Van Thiel, University of California, Radiation  
Laboratory, Livermore, Calif.

Undergraduate student personnel

Gerry Rollefson
