EVALUATION OF PRESSURE DISTRIBUTION
ON A CAVITATING HYDROFOIL WITH FLAP

by
Zora L. Harrison
and
Duen-pao Wang

This work was carried out under the
Bureau of Ships General Hydrodynamics Research Program,
Administered by the David Taylor Model Basin,
Office of Naval Research Contract Nonr-220(52).

Reproduction in whole or in part is permitted for
any purpose of the United States Government

Report No. E-133.1

September 1965
ABSTRACT

A general method is established to calculate the pressure distribution and the moment of force for a two-dimensional, supercavitating hydrofoil with a flap. The wake flow model is adopted to describe the configuration of the flow field. Some numerical results for a supercavitating flat plate with a flap are compared with the corresponding experimental data.
NOMENCLATURE

A  a scale factor
a, a distances from the hinge point, P, to the respective centers of pressure of the main body and the flap
AR  aspect ratio
c, c distances along the chord, measured from the hinge point
C_D  total drag coefficient
C_{F_1}, C_{F_2}  total normal force coefficients acting at the centers of pressure
C_L  total lift coefficient
C_{M_1}, C_{M_2}  moment coefficients about the hinge point
C_{M_H}  moment coefficient of the flap about the hinge point, C_{M_H} = C_{M_2}
C_{M_LE}  total moment coefficient about the leading edge
C_p, C'_p  pressure coefficients
C_{x_1}, C_{x_2}  force components in x-direction
C_{y_1}, C_{y_2}  force components in y-direction
f(t)  complex potential
f/c  flap to chord ratio
g(t; t_o)  an analytic function: g(t; t_o) = \frac{1}{2\pi i} \frac{df(t)}{dt}
H  function in the integrand of a
h/c  the ratio of the depth of submergence to the chord length
I_1, I_2  integrals in the calculation of I_1 and I_2
J_1, J_2  Cauchy integrals in the calculation of chord length
\( l_1, l_2 \) chord lengths: \( l_1 + l_2 = 1, \ f/c = l_2 / (l_1 + l_2) \)

\( Q \) function in the integrand of \( V_a \)

\( r_1, r_2 \) distance parameters in the calculation of \( V_f \) and \( \beta_f \) (note the subscripts 1 and 2 do not refer to the main body and the flap for these parameters)

\( R \) the prescribed value of \( f/c \)

\( s(x) \) chord distance measured from the leading edge

\( t \) a mapping plane of the flow region

\( t_o \) image point of \( z = \infty \) in the \( t \)-plane: \( t_o = Ve^{-i\beta} \)

\( T \) image of the hinge point in the \( t \)-plane

\( U \) free stream velocity: \( U^{-2} = 1 + \sigma \)

\( V \) magnitude of \( t_o \)

\( w(t) \) complex velocity

\( x \) coordinate in \( z \)-plane and transformation variable

\( y \) coordinate in \( z \)-plane

\( z \) physical plane

\( \alpha \) angle of attack

\( \beta \) polar angle of \( t_o \) in the \( t \)-plane

\( \epsilon \) flap angle

\( \theta_1, \theta_2 \) angles between the tangents to the foil profile and the chords

\( \sigma \) cavitation number

\( \tau \) integration variable in the \( t \)-plane
Introduction

In practical applications of supercavitating hydrofoils the adoption of flaps or other load modulators as motion control devices is of fundamental importance. An accurate determination of the moment and hinge-moment acting on supercavitating hydrofoils with deflected flaps is essential to the structure design on one hand, and to the development of successful control and maneuverability on the other. Furthermore, a detailed study of the pressure distribution is also valuable for establishing the general validity of any theoretical model and also for elucidating the role of effectiveness of the flap.

Recently, the supercavitating flap problem has been investigated using the linearized theory for the case of zero cavitation number, corresponding to an infinitely long cavity. The case of infinite flow extent was first treated by Tulin and Burkart [1]. This theory has been extended by Johnson [2] who incorporated the classical work of Kirchhoff and Rayleigh, and that of Green, the latter including the effect of the free water surface, but neglecting the gravity effect. In Johnson's theory, an estimate of the effect of finite aspect ratio is also evaluated. A linearized theory was subsequently developed by Auslaender [3] for the case of zero cavitation number and at a finite depth of submergence. Using a nonlinear theory, Lin [4] treated the flap problem for the flat plate hydrofoil at zero cavitation number. In an approximate sense, the limiting condition of zero cavitation number corresponds to the shallow submergence case when the

1 Numbers in brackets designate references at end of paper.
cavity becomes completely open to the atmosphere. However, a fine
difference in this correspondence arises from the fact that the dynamic
effect due to the upper half flow field is actually modified in the pre-
sence of a free water surface at shallow submergences. In accordance
with this analogous configuration, some model investigations with flaps
have been carried out by Johnson [2], Brown [5], Conolly [6] and Wetzel
and Maxwell [7]. In order to establish the fully cavitating configuration
at small incidences, the technique of base ventilation has been employed
in some cases of these experiments.

The objective of the present investigation is to establish a general
and systematic method for calculating accurately the pressure distribu-
tion, moment of force, and hinge-moment acting on a supercavitating
hydrofoil of arbitrary profile, especially when the angle of attack, flap
deflection and the cavitation number are moderate or large. This calcu-
lation is based on the nonlinear theory developed recently by Wu and
Wang [8]. To meet the general operating conditions in practice, this
theory can be further extended to include the effects of free water sur-
face and gravity, and finally the effect of finite aspect ratio and three-dim-
ensional features. The scope of the present work, however, will be limited
to the case of two-dimensional flow of infinite extent, with emphasis on the
pressure distribution over a flapped hydrofoil. The formulas for the force
moment and hinge-moment are also derived here. Since the information
about pressure distribution in cavity flows is relatively scarce in the ex-
isting literature, it is hoped that the results of this study may provide use-
ful data for future applications as well as for further development of this
general field.
The numerical computation has been performed with an IBM 7094 Computer, for which the method and computing program are explained in detail in this report. The final results for the case of flat plate hydrofoil with a flap are presented in figures for different angles of attack, flap angles, flap-chord ratio and the cavitation number. The calculation for hydrofoils of arbitrary profile is also discussed. The computation program for this case follows an approximate numerical scheme developed by Wu and Wang [9]. This approximate method greatly shortens the computation of the final integral equations in the theory, while still retaining a high degree of accuracy of the result.

A parallel experimental program has been accomplished by Meijer, the results of these experiments will be presented in a separate report by Meijer [10]. It can be stated here that the general agreement between the theory and experiments is very satisfactory, and the experimental observation has also revealed some interesting points, such as the viscous effect near the flap hinge. With the theory now well established in the typical cases so far investigated, the present method can be applied with confidence for the general case of arbitrary profile.

**General Formulation**

We consider a steady, irrotational plane flow of an incompressible fluid past an arbitrary profile AB in such a way that the flow is separated from the leading and trailing edges A and B, forming a fully developed cavity behind the foil AB. The foil AB consists of a main foil AP and a flap PB, as shown in Fig. 1(a). A set of Cartesian coordinates, x and
y, is chosen with the origin at the leading edge A and the x-axis lying along the chord AP. The incoming free stream has a speed $U$ and is at an angle of attack $\alpha$ to the x-axis. The flap angle, $\alpha_{\pi}$, is the angle measured from the x-axis to the chord of the flap PB, positive in the clockwise sense.

In the following analysis the wake flow model, as formulated in [8], will be used to describe the flow. For the sake of convenience, a general description of the wake model will be given briefly in the following: The part AC and BC' of the free streamlines, as shown in Fig.1(a), form the boundary of a near-wake of constant pressure $p_c$, which is less than the free stream pressure $p_{\infty}$. From this part onward the pressure varies continually and monotonically from $p_c$ to $p_{\infty}$, along the far-wake boundary, CI and C'I. It is further assumed that the values of the complex potential, $f$, and the complex velocity, $w$, at the point C are equal to those at the point C' respectively. With the introduction of the so-called "hodograph-slit condition" for the streamlines CI and C'I, we assume that the entire flow region in the $z$-plane can be mapped onto the interior of the lower-half unit circle in a $t$-plane, as shown in Fig. 1(b), where $T$ is the image of the point $P$, and $T_0$ that of the point $I$. On the $t$-plane the complex potential, $f$, and the complex velocity, $w$, with the speed on the cavity wall normalized to unity, can be written respectively as

$$f = \frac{At^2}{(t-t_0)(t-\frac{1}{t_0})(t-\frac{1}{t_0})}, \quad (1a)$$
and

\[ w = t \left( \frac{t-T}{tt-1} \right)^{\frac{3}{2}} \left\{ \exp \left[ -\frac{(1-t^2)}{\pi} \sum_{1}^{t} \frac{\theta(z(\tau)) d\tau}{(\tau-t)(\tau-1)} \right] \right\}, \quad (1b) \]

where \( \theta(z(\tau)) \) is the angle measured from the chord \( AP \) (or, chord \( PB \)), counter-clockwise as positive, to the tangent at any point \( z \) on the surface profile curve \( AP \) (or, curve \( PB \)), as shown in Fig. 1(a). At \( z = \infty \), \( w = U e^{-\text{in}} \) and \( t = t_0 \), hence

\[ t_0 = U e^{-\text{in}} \left( \frac{Tt_0 - 1}{t_0 - T} \right)^{\frac{3}{2}} \left\{ \exp \left[ -\frac{(1-t^2)}{\pi} \sum_{1}^{t} \frac{\theta(z(\tau)) d\tau}{(\tau-t)(\tau-1)} \right] \right\}. \quad (2) \]

For any point on the foil, corresponding to \( t = \tau \), \( \tau \) being real, \(-1 < \tau < 1\), the distance along \( AP \) and \( PB \) between the leading edge \( A \) and the projection of this point to \( AP \) or \( PB \) is given by:

\[ c(\tau) = 2A \int_{-1}^{1} \left| \frac{1-T}{T-t} \right| \left( 1 + t^2 - \frac{1}{2} \right) \left( \frac{1}{1 + \frac{t}{t_o} (1 + t^{-1})} \right) \cos \theta(\tau(t)) dt \]

\[ \left( 1 + t^2 - \frac{1}{2} \right) \left( \frac{1}{1 + \frac{t}{t_o} (1 + t^{-1})} \right) \]

where \( * \) above the integral sign signifies that the Cauchy principal value of the integral is taken and

\[ g(t; t_0) = \frac{1}{2A \left( 1 + t^2 - \frac{1}{2} \right)} \left( 1 + \frac{t}{t_o} (1 + t^{-1}) \right) \left( 1 + \frac{t}{t_o} (1 + t^{-1}) \right) \]

The condition that the points \( C, C' \) lie on the lower unit circle in the \( t \)-plane, or \(-\pi < \arg t_c < 0\), may be expressed as

\[ -1 < \text{Re} \left( \frac{1}{t_o} \right) < 1. \]
This condition is equivalent to stating that the constant pressure region extends beyond the trailing edge B.

By writing $t_0 = Ve^{-i\beta}$, Eq. (4) becomes

$$
g(t; t_0) = \frac{V^4 (1 - e^2)(1 + t^2 - (1 + V^{-2})(tV \cos \beta))}{[(t^2 + V^2 - 2tV \cos \beta)(t^2V^2 - 2tV \cos \beta + 1)]^2}.
$$

Similarly, substituting $t_0 = Ve^{-i\beta}$ into Eq. (2), expanding and separating the real and imaginary parts, we obtain the parametric relations for $t_0$ as follows

$$
V = V_f V_a,
$$

and

$$
\beta = \beta_f + \beta_a,
$$

where

$$
V_f = U \left( \frac{T}{\pi} \right)^{\frac{\epsilon}{2}},
$$

$$
V_a = \exp \left[ \frac{1}{\pi} \int_{-1}^{1} Q(t) \theta(t) \, dt \right],
$$

$$
\beta_f = a + \epsilon \left\{ \cos^{-1} \left[ \frac{r_1^2 + r_2^2 - \left( \frac{1}{T} - T \right)^2}{2r_1 r_2} \right] \right\},
$$

$$
\beta_a = -\frac{1}{\pi} V \sin \beta \int_{-1}^{1} \theta(t) \, dt,
$$

$$
r_1 = (T^2 + V^2 - 2TV \cos \beta)^{\frac{1}{2}},
$$

$$
r_2 = (T^{-2} + V^2 - 2T^{-1}V \cos \beta)^{\frac{1}{2}},
$$
\[ Q(t) = \frac{tV^2 - V \cos \beta}{t^2 V^2 - 2tV \cos \beta + 1} - \frac{t - V \cos \beta}{t^2 + V^2 - 2tV \cos \beta} \]  

(14)

and

\[ H(t) = \frac{1}{t^2 V^2 - 2tV \cos \beta + 1} + \frac{1}{t^2 + V^2 - 2tV \cos \beta} \]  

(15)

Let \( J(t) \) denote the Cauchy integral in Eq. (3). Then, noting that

\[ \int_{-1}^{1} \frac{d\tau}{(\tau - t)(\tau - 1)} = 0, \]

the singularity of the integrand in \( J(t) \) can be removed, giving

\[ J(t) = \int_{-1}^{1} \frac{\theta(\tau) - \theta(t)}{(\tau - t)(\tau - 1)} \, d\tau. \]

\[ = \int_{-1}^{T} \frac{\theta(\tau) - \theta(t)}{(\tau - t)(\tau - 1)} \, d\tau + \int_{T}^{1} \frac{\theta(\tau) - \theta(t)}{(\tau - t)(\tau - 1)} \, d\tau. \]  

(16)

If we let the chord of \( AP \) be \( l_1 \) and the chord of \( PB \) be \( l_2 \), then

\[ l_1 = 2A \int_{-1}^{T} \left| \frac{1 - Tt}{T - t} \right| g(t; t_o) \left\{ \exp \left[ \frac{(1 - t^2)}{\pi} \right] J_1(t) \cos \theta_1(t) \right\} \, dt \]

and

\[ l_2 = 2A \int_{T}^{1} \left| \frac{1 - Tt}{T - t} \right| g(t; t_o) \left\{ \exp \left[ \frac{(1 - t^2)}{\pi} \right] J_2(t) \cos \theta_2(t) \right\} \, dt \]  

(17)

where \( l_1, l_2, \theta_1 \) and \( \theta_2 \) are shown in Fig. 1c. For given \( U, \sigma, \theta(x) \), \( l_1 \) and \( l_2 \), Eqs. (2), (3) and (17) provide a set of functional equations

\[ \text{† The subscripts 1 and 2 in all following equations refer to the main foil and the flap respectively.} \]
for unknown \( t_o \), \( c(\tau) \), \( A \) and \( T \).

To facilitate the numerical computation of the above integrals it is convenient to introduce the following changes of variables

\[
t_1(x) = \frac{T - x^2}{1 - Tx^2}, \quad t_2(x) = \frac{T + x^2}{1 + Tx^2};
\]

so that \( t_1 \) varies from \( T \) to \(-1\), \( t_2 \) from \( T \) to \(+1\), as \( x \) increases from 0 to 1. Then Eq. (17) may be written as

\[
f_k = 4A(1 - T^2)I_k
\]

where, with \( k = 1, 2 \),

\[
I_k = \int_0^1 \frac{x(1 - 2x)}{[1 + (\tau)^kTx^2]^2} \frac{g(t_k(x); t_o)}{\psi^4} \left\{ \exp \left[ \frac{1 - t_k^2}{\pi} J_k(x) \right] \cos \theta_k(x) \right\} dx,
\]

and

\[
J_1(x) = 2(1 - T^2) \left[ \int_0^1 \frac{[\theta_1(u) - \theta_1(x)] u du}{(\tau - t)(\tau t_1 - 1)(1 - Tu^2)^2} + \int_0^1 \frac{[\theta_1(u) - \theta_1(x)] u du}{(\tau - t)(\tau t_2 - 1)(1 - Tu^2)^2} \right],
\]

\[
J_2(x) = 2(1 - T^2) \left[ \int_0^1 \frac{[\theta_2(u) - \theta_2(x)] u du}{(\tau - t)(\tau t_1 - 1)(1 - Tu^2)^2} + \int_0^1 \frac{[\theta_2(u) - \theta_2(x)] u du}{(\tau - t)(\tau t_2 - 1)(1 + Tu^2)^2} \right].
\]

\( \theta_1(x) \) and \( \theta_2(x) \) in Eqs. (20) and (21) are the angles between the tangents and the chords of \( AP \) and \( PB \) at \( c_1(x) \) and \( c_2(x) \) respectively, as shown in Fig. 1(c).

If we now normalize the total chord \( (t_1 + t_2) \) to be unity, we have

\[
A = \frac{1}{4(1 - T^2)(I_1 + I_2)};
\]
and hence

\[
c_k(y) = \frac{1}{1 + \frac{1}{2}} \int_0^y \frac{x^{(1 - 2\epsilon)}}{[1 + \epsilon^2 T^2 x^2]^{\frac{1}{2}}} \frac{g(t_k(x); t_o)}{V^4} \left\{ \exp \left[ \frac{1 - t_k^2}{\pi} \right] J_k(x) \cos \theta_k(x) \right\} dx,
\]

\((k = 1, 2)\)

The ratio of the flap chord \( f \) to the total chord \( c \) is

\[
f/c = \frac{I_k^2 + J_k^2}{I_k^2 + J_k^2} = \frac{I_k^2 + J_k^2}{I_k^2 + J_k^2}.
\]

Making the same changes of variable, Eqs. (9) and (11) become

\[
V_a = \exp \left\{ \frac{2}{\pi} (1 - T^2) \left[ \int_0^1 \frac{x \theta (x)}{(1 - Tx^2)^{\frac{1}{2}}} + \int_0^1 \frac{x \theta (x)}{(1 + Tx^2)^{\frac{1}{2}}} \right] \right\}
\]

and

\[
\beta_a = -\frac{2}{\pi} V \sin \beta (1 - T^2) \left[ \int_0^1 \frac{x \theta (x)}{(1 - Tx^2)^{\frac{1}{2}}} + \int_0^1 \frac{x \theta (x)}{(1 + Tx^2)^{\frac{1}{2}}} \right],
\]

where \( Q \) and \( H \) are given by Eqs. (14) and (15) respectively.

The pressure coefficient at any point is

\[
C_p = \frac{P - P_c}{\frac{1}{2} \rho U^2}
\]

where \( P \) is the pressure at the wetted surface of the plate and \( P_c \) the constant pressure in the cavity. From the Bernoulli equation we obtain

\[
C_p = U^{-2} (1 - q^2) = (1 + \delta)(1 - q^2)
\]
or

\[ C_p = (1 + \sigma)(1 - \bar{w} \bar{w}) , \]  

(28b)

where \( \sigma \) is the wake under-pressure coefficient, or the cavitation number for cavity flows, given by \( \sigma = \frac{P_w - P_c}{\frac{1}{2} \rho U^2} \), and \( \bar{w} \) is the complex conjugate of \( w \).

The complex force coefficient for the main body, \( C_x + iC_y \), can be written as

\[
C_x + iC_y = i \int_{P}^{A} C_p \, dz = i(1 + \sigma) \int_{A}^{P} (1 - w \bar{w}) \, dz
\]

\[
= i(1 + \sigma) \left[ (z_P - z_A) - \int_{-1}^{T} \frac{\bar{w}}{\bar{w}} \frac{df}{dt} \, dt \right],
\]

(29)

From Eqs. (1), (4), (22) and the transformation (18), we can write the above equation as

\[
C_x + iC_y = i(1 + \sigma) \left[ \int_{1}^{l} \right. 
- \frac{1}{1 + \frac{1}{2}} \int_{0}^{1} x^t \left( 1 + 2 \epsilon \right) t^2(x) \frac{g(t(x); t_o)}{V^4} \exp \left\{ - \frac{[1 - t^2(x)]}{1} \right\} J_1(x) \left| e^{i \theta_1} \, dx \right].
\]

(30a)

Similarly, the complex force coefficient for the flap, \( C_x + iC_y \), becomes

\[
C_x + iC_y = i(1 + \sigma) e^{-i \pi} \left[ \int_{2}^{l} \right. 
- \frac{1}{1 + \frac{1}{2}} \int_{0}^{1} x^t \left( 1 + 2 \epsilon \right) t^2(x) \frac{g(t(x); t_o)}{V^4} \exp \left\{ - \frac{[1 - t^2(x)]}{2} \right\} J_2(x) \left| e^{i \theta_2} \, dx \right].
\]

(30b)
The lift and drag coefficients, $C_L$ and $C_D$, are given by

$$C_D + iC_L = [(C_{x_1} + iC_{y_1}) + (C_{x_2} + iC_{y_2})] e^{-i\alpha}.$$  \hspace{1cm} (31)

**Special Case: Flat Plate**

As a special case, we now consider a flat plate with a flap as shown in Fig. 2. This configuration is particularly simple since $\theta = 0$ everywhere along the chord. By putting $\theta = 0$ in our formulae, $V_a$ given by Eq. (9) becomes unity and $\beta_a$ given by Eq. (11) becomes zero so that

$$V = V_f$$  \hspace{1cm} (32)

and

$$\beta = \beta_f,$$  \hspace{1cm} (33)

where $V_f$ and $\beta_f$ are given by Eqs. (8) and (10) respectively. Similarly $w$, $I_1$, $I_2$, $c_1$ and $c_2$ are given by Eqs. (1b), (20) and (23) with the factor inside the curly brackets equal to unity.

From the above and Eq. (28b) we obtain the pressure coefficient

$$C_p = (1 + \sigma)[1 - t^2 \left| \frac{T - t}{T + t} \right|^{2k}] .$$  \hspace{1cm} (34)

In terms of the variable $x$ defined by Eq. (18), Eq. (34) may be written as

$$C_{p_k}(x) = (1 + \sigma)[1 - t_k^2(x)x^{2k}] , \quad (k = 1, 2).$$  \hspace{1cm} (35)

The moment coefficients about the hinge point $P$ due to the pressure over the main foil, $AP$, and of the flap, $PB$, as shown in Fig. 2, are

$$C_{M_1} = \int_{-1}^{T} C_{p_1}(t)c_1(t) \, dc_1.$$
and

\[ C_{M_2} = \int_T^1 C_{p_2} c_2(t) \, dc \]

respectively. From Eq. (23) we get

\[ C_{M_k} = \frac{1}{(I_1 + I_2)^2} \int_0^1 C_{p_k} \left\{ x \left( \frac{1}{1 + (-)^k T x^2} \right)^2 \right\} dy \, dx, \]

\[ \left( k = 1, 2 \right) \]

where \( I_1 \) and \( I_2 \) are given by Eq. (20) with the factor inside the curly brackets equal to unity and \( g(t; t_0) \) is given by Eq. (4).

It is also desirable to know the location of the centers of pressure of both the main body and the flap as well as the total forces at those points. Let \( a_1 \) and \( a_2 \) be the distances from the hinge point, \( P \), to the center of pressure on the main foil and to that on the flap respectively, and let \( C_{F_1} \) and \( C_{F_2} \) be the force coefficients acting at these points.

We may now write

\[ C_{F_1} = \int_{-1}^T C_p \, dc, \quad C_{F_2} = \int_T^1 C_p \, dc, \]

with the help of Eq. (23) the final results are

\[ C_{F_k} = \frac{1}{I_1 + I_2} \int_0^1 C_{p_k} \left( \frac{x \left( \frac{1}{1 + (-)^k T x^2} \right)^2 \right) \right\} g(t_k(x); t_0) \, \frac{1}{V^4} \, dx, \quad \left( k = 1, 2 \right) \]

\[ (38) \]

\[ a_k = \frac{C_{M_k}}{C_{F_k}}, \quad \left( k = 1, 2 \right). \]

\[ (39) \]
Knowing these quantities we can transfer the total moment to the leading edge, giving

\[ C_{M_{LE}} = C_{F_1}(\ell_1 - a) + C_{F_2}(\ell_1 \cos \pi + a) \]  

(40)

where \( C_{M_{LE}} \) is considered to be positive in the nose down sense. The hinge moment is defined as the moment of the flap about the hinge point, hence

\[ C_{M_H} = C_{M_2} \]  

(41)

The pressure distribution is given in the parametric form \( s(x) \), \( C'_p(x) \), where \( s(x) \) denotes the length along the foil surface measured from the leading edge such that \( 0 \leq s \leq 1 \),

\[ s(x) = 1 - \frac{c}{c} - c_1(x) \quad \text{on AP} \]

\[ = 1 - \frac{f}{c} + c_2(x) \quad \text{on PB} \]  

(42)

and \( C'_p \) is the pressure coefficient which is defined as unity at the stagnation point \( D \) and is equal to negative \( \sigma \) on the cavity side. Then we have

\[ C'_{p_k}(x) = (1 + \sigma) \left[ 1 - t_k^2(x) x^4 \right] - \sigma, \quad (k = 1, 2). \]  

(43)

The lift and drag coefficients are given by (referring to Eq. (78) of Ref. (8))

\[ C_L = \frac{wA}{U^2} \frac{(U^2 + U) \cos \beta}{(V^2 + V^2 - 2 \cos 2 \beta)} \left\{ \frac{\cos \beta + t (1 - T^2)(1 + T^2)V^2 \cos \beta}{(T^2 + V^2 - 2tV \cos \beta)(T^2V^2 + 1 - 2tV \cos \beta)} \right\} \]  

(44)
\[
C_D = \frac{\pi \Delta}{U^2} \frac{(U^2 - U)/(1 - V^2)}{(V^2 + V^2 - 2 \cos 2\beta)} \left\{ 1 + V^2 + \frac{\epsilon(1 + T^2)(1 + T^2) \cos 2\beta(1 + V^2)}{(T^2 + V^2 - 2 \cos 2\beta)(T^2 V^2 + 1 - 2TV \cos 2\beta)} \right\}
\]

where \( \Delta \) is given by Eq. (22).

**Numerical Procedures:**

a) Flat plate with a flap.

A double iteration procedure is required to evaluate the force coefficients for prescribed \( U, a, e \) and \( f/c \). We first solve the inverse problem: choose \( U, a, e \) and \( T \) as the independent parameters, solve for \( V \) and \( \beta \) (hence \( T_0 \)) by iterating the parametric relations in Eqs. (32) and (33). We then obtain the corresponding flap-to-chord ratio, \( f/c \) \( = I_2/(I_1 + I_2) \), where \( I_1 \) and \( I_2 \) are given by Eq. (20) with the factors inside the curly brackets equal to unity. A type of iteration similar to Newton's method is then used on \( T \) to find \( V \) and \( \beta \) corresponding to the desired value of \( f/c \).

Once \( V \) and \( \beta \) are established, the moment coefficients, \( C_{M,LE} \) and \( C_{M,H} \), are obtained from Eqs. (37)-(41), the pressure distribution from Eqs. (42) and (43) and drag coefficients from Eqs. (44) and (45).

The details of the calculations outlined above are described in Appendix A.

* The program listing is available upon request.
b) Arbitrary profile.

The iteration scheme for the arbitrary profile is a combination of the above method and the approximate scheme of Wu and Wang [9] and is described in detail in Appendix B*.

Results:

The numerical calculations outlined above were carried out for three models of flapped flat plate hydrofoils with flap to chord ratios of 0.2, 0.4 and 0.6. For each model the flap angle, $\epsilon \pi$, was varied from $10^\circ$ to $60^\circ$ and the angle of attack, $\alpha$, from $5^\circ$ to $60^\circ$ for cavitation numbers between 0 and 1.0**.

Figures 3 through 5 show the total moment coefficient about the leading edge, $C_{MLE}$, and the moment of the flap about the hinge point, $C_{MH}$, as functions of $\alpha$ for $\alpha = 5^\circ$ through $60^\circ$. For each model the flap angles $10^\circ$, $20^\circ$, $40^\circ$ and $60^\circ$ are shown. $C_{MLE}$ as a function of $\epsilon \pi$ is given in Fig. 6 for all three models at various cavitation numbers for $\alpha = 10^\circ$, $20^\circ$ and $30^\circ$. Figure 7 shows the lift coefficient, $C_L$, versus $\epsilon \pi$ for the same conditions. The polar plots of $C_L/C_D$ versus $C_L$ for $\sigma = 0$ are shown in Fig. 8, in which the solid lines are lines of constant $\alpha$ and the dashed lines are those of constant $\epsilon \pi$. Since, within the range of the cavitation numbers concerned, $C_L/C_D$ is almost independent of $\sigma$, no corresponding curves are needed for other values of $\sigma$.

Some typical pressure distribution curves for the model with

---

* The program listing is available upon request.

** Tabulated results are available upon request.
The experimental points are taken from the work by Meijer. In Meijer’s experiments, different sized models were tested in order to make wall effect corrections. In Fig. 9 the theoretical results agree very well with the experimental ones, except around the hinge region. The discrepancy there may be attributed to viscous effect. Curves were faired through Meijer’s experimental points, given in Fig. 9, and then integrated to obtain $C_L$ and $C_D$. The results are plotted along with the corresponding theoretical lift and drag curves in Fig. 10. As would be expected from the pressure distribution correlation in Fig. 9, the agreement in $C_L$ and $C_D$ is very good.

Figure 11 illustrates the agreement between Parkin’s experiment and the theory of $C_{M_{LE}}$ as a function of $\alpha$ for a flat plate at angles of attack from $10^\circ$ to $30^\circ$. The experimental points of Parkin’s experiment have not been corrected for wall effects.

Besides the above comparisons between two-dimensional results, it is also interesting to compare the present two-dimensional theoretical results with experiments having three-dimensional effect. Wetzel and Maxwell performed experiments with ventilated finite aspect ratio models at different submergences in a free jet. Some of these results are shown in Figs. 12 and 13. In general, the agreement between the two-dimensional theory and three-dimensional flow is not as good as the agreement with the two-dimensional experiments of Parkin and Meijer, but as aspect ratio and submergence are increased the agreement tends to improve.
ACKNOWLEDGMENT

The authors wish to express their sincere thanks to Professor T. Y. Wu for his many helpful suggestions and his guidance in this problem, to Miss Cecilia Lin for the drawings and to Mrs. Mary Goodwin for typing the manuscript.

APPENDIX A

The double iteration procedure outlined in the text for the flat plate problem presents no problem when done on a high speed computer. All calculations presented here were done on the IBM 7094 at Booth Computing Center, California Institute of Technology.

Choose $U$, $\alpha$, $\epsilon$ and let the first approximation of $T$ be 0.5, then calculate $V$ and $\beta$ by iteration of Eqs. (32) and (33). Since $V$ and $\beta$ are rather close to $U$ and $\alpha$ in value, let $V(0) = U$ and $\beta(0) = \alpha$ be the first approximations, then

$$V^{(1)} = V_f(T, V(0), \beta(0))$$

and

$$\beta^{(1)} = \beta_f(T, V(0), \beta(0))$$

are the next approximations. Continue this procedure until $|V^{(n-1)} - V^{(n)}|$ and $|\beta^{(n-1)} - \beta^{(n)}|$ are less than the allowable error. This iteration converges very well; on the average about 6 iterations will produce an accuracy such that the error is less than 0.00001.

Once $V$ and $\beta$ are determined the corresponding flap to chord ratio, $f/c$, can be calculated from Eq. (24), where $I_1$ and $I_2$ are given by Eq. (20) with the curly brackets equal to one. Let the desired $f/c$ be $R$ and the first approximations to $T$ and $f/c$ be $T(0)$ and $R(0)$ respectively. Since $f/c$ decreases as $T$ increases, the second approximation to $T$ is arbitrarily set to be either

$$T^{(1)} = 0.1; \quad R - R^{(0)} > 0$$
or

\[ T^{(1)} = 0.9; \quad R - R^{(0)} < 0. \]

The corresponding \( R^{(1)} \) is calculated from the first iteration process and now we can apply a modified Newton's method,

\[ T^{(2)} = T^{(0)} + \left[ R - R^{(0)} \right] \left[ \frac{T^{(0)} - T^{(1)}}{R^{(0)} - R^{(1)}} \right] \]

and

\[ R^{(2)} = \frac{f}{c} \left( T^{(2)} \right). \]

Continue these successive approximations of \( T \) according to

\[ T^{(n+1)} = T^{(n-1)} + \left[ R - R^{(n-1)} \right] \left[ \frac{T^{(n-1)} - T^{(n)}}{R^{(n-1)} - R^{(n)}} \right] \]

until \( |R - R^{(n-1)}| \) is less than the allowable error.

It should be pointed out here that only positive values of \( T \) are of interest for the physical application considered here. If \( T \) becomes negative then the stagnation point \( D \) has moved to the flap side of the hinge point. This situation occurs when \( f/c \rightarrow 1 \) and \( \alpha \) and \( \epsilon \) become large.

Once \( T, V, \) and \( \beta \) are determined the pressure distribution, lift, drag and moment coefficients are readily calculated as outlined in the text. The numerical integration required was programmed using Simpson's rule on increments of \( x = 0.005 \) and \( y = 0.0001 \). This increment size was sufficiently small to produce an accuracy of at least \( \pm 0.0001 \) for all cases that were calculated. A good check of the accuracy is to print out \( s_1(x = 1) \) and \( s_2(x = 1) \) as these values should be 0 and 1.0 respectively.
APPENDIX B

The iteration procedure required for the arbitrary profile is somewhat longer and more complex than the flat plate problem because of the added slope function, \( \theta \). This additional parameter gives rise to an integration in the \( V \) and \( \beta \) calculations; furthermore, the chord calculation becomes a double integral. We have used a modification of the approximate numerical scheme originated by Wu and Wang [10]. This modification is necessary because of the additional requirement of fixed \( f/c \) so that \( T \) cannot be prescribed as it was in that reference.

We first solve the flat plate problem for the prescribed \( \alpha, \sigma, \epsilon \) and \( f/c \). This solution gives us a good first approximation for the unknown parameters \( V, \beta \) and \( T \). Using these initial values we now iterate Eqs. (6), (7) and (24) except that the value of \( c(x) \), required to determine \( \theta(x) \), is the flat plate value given by Eq. (23) with the curly brackets equal to one (since \( \theta \) is equal to zero). The values so calculated are designated with *. As before we let the prescribed \( f/c \) be \( R \) and the calculated \( f/c \) be \( R^{(n)} \). This time we do not iterate \( V^* \) and \( \beta^* \) for each value of \( T^* \) (and hence \( R^* \)) because they are less sensitive than \( R^* \) to changes in \( T^* \). It is also necessary to adjust the chord values \( c_1(x) \) and \( c_2(x) \) at each iteration so that \( c_1(x = 1) = 1 - R \) and \( c_2(x = 1) = R \). This adjustment in the chord values is necessary because the \( \epsilon \) values are defined only in the regions \( 0 \leq c_1 \leq 1 - R \) and \( 0 \leq c_2 \leq R \). With these exceptions this iteration is carried out in the same way as in the flat plate iteration until

\[
V^{*}(n-1) - V^{*}(n), \quad \beta^{*}(n-1) - \beta^{*}(n) \quad \text{and} \quad R^{*}(n) - R
\]
are less than the allowable error. We then calculate the exact value of
\( c(x) \) (with the curly brackets) and recalculate \( V^{(n)} \), \( \beta^{(n)} \) and \( R^{(n)} \). If
necessary this last step is iterated until

\[
| V^{(n-1)} - V^{(n)} |, | \beta^{(n-1)} - \beta^{(n)} | \quad \text{and} \quad | R^{(n)} - R |
\]

are less than the allowable error. When the camber is small it is found
that it is not necessary to iterate this last step.

Our program is written so that the \( \theta \) values may be obtained
either by a four point interpolation from a stored set of \( \theta \) versus \( c \)
values or from an analytic expression.

# Evaluation of Pressure Distribution on a Cavitating Hydrofoil with Flap

## Abstract

A general method is established to calculate the pressure distribution and the moment of force for a two-dimensional, supercavitating hydrofoil with a flap. The wake flow model is adopted to describe the configuration of the flow field. Some numerical results for a supercavitating flat plate with a flap are compared with the corresponding experimental data.
1. Cavity Flow
2. Hydrofoil with a Flap
3. Pressure Distribution and Moment of Force
