AS 1938
FOREWORD

This technical report, "PCDE Studies," was prepared under Contract No. 04611-72-C-0046 as partial fulfillment of the requirements of the Air Force Rocket Propulsion Laboratory, Research and Technology Division, Air Force Systems Command, Edwards, California. The work reported was done in the Propellant Development Department, Advanced Propellants Section of the Aerojet Solid Propulsion Company, Sacramento, California. This report, designated Aerojet Report 1938-76SA-3, records the results of work done during the interval 1 March to 31 August 1973. The program was monitored by Captain A. Crelier.

Acknowledgement is made to the following persons who have contributed materially to the work performed during this period: Mr. J. Newey, for propellant formulation; Mr. I. Hazelton, for mechanical testing; Mr. T. Hickmon, for burning rate studies; Messrs. A. A. Almada and O. Dizney, for supporting efforts; and Mr. F. O'Dell, for safety testing.
(C) A PCDE-TMETN propellant has been developed and made in six 1-gal and three 5-gal batches. The formulation which consists of 40.5 wt% HMX, 20.5 wt% AP, and 18 wt% Al, and a binder based on equal parts of PCDE and TMETN is calculated to have a theoretical specific impulse of 271.2 of which 256.5 will be delivered in the Aerojet 10KS2500 motor. The propellant density is 0.06842 lb/in^3. At 125°F, the processing temperature, the propellant is Aerojet Type 3 and does not require remote handling.
20. (Cont.)

(U) One of the 5-gal batches, made to provide aging samples for the Lockheed Propulsion Company, showed colored inclusions surrounded by larger areas of poorly cured propellant. Analysis of these indicated larger than normal concentrations of Zn, FeAA, and DNDPA. The conclusion was that these materials arose from poor dispersal of a mixture of ZnO, FeAA, sulfur, and DNDPA which is added to the prepolymer just previous to mixing. More efficient dispersal should alleviate the problem.

(C) The burning rate of the propellant is 0.466 in./sec at 1000 psia with a pressure exponent of 0.60. The $\eta_k$ is 0.2%/°F between -65° and 150°F. In R&C 2C1.5-4 motors fired at AFRPL the burning rate was 0.49 in./sec at 1000 psia with a pressure exponent of 0.53.

(U) The propellant ages poorly at 150°F, but maintains adequate mechanical, safety, and ballistic properties at 110° and 77°F for more than eight weeks.

(C) Currently being developed is a PCDE-BDNPA/F propellant. The candidate formulation consists of 51 wt% AP, 22 wt% Al, and a binder based on PCDE and BDNPA/F at a ratio of 1.1 to 1. The calculated theoretical specific impulse of this Class 2 propellant is 263.4 of which 250.8 is delivered in a large motor. Propellant density is 0.0680 lb/in³. The chief problem is to achieve a burning rate of 1.3 in./sec at 1000 psia. Although this can be done by the use of iron oxide or by use of 1µ or 3µ AP, some difficulties of reproducing earlier values with propellants containing 0.5µ AP have been experienced. No major technical difficulty to achieving the burning rate is expected. Processing studies of this propellant have begun, and early work indicates a potlife in excess of four hours.

GLOSSARY (Cont.)

Ω
Performance parameter based on final boost velocity

P711
Plastinox 711, stabilizer, di(tridecyl) thiodipropionate

π_k
Temperature sensitivity of operating pressure at constant area ratio

(C) PCDE
Prepolymer, poly(1-cyano-1-difluoraminoethylene oxide)

R&H
Rohm & Haas

RRD
Rounded rotary-dried (in reference to AP)

S-8
Stabilizer, N-ethyl toluenesulfonamide

σ
Mechanical property parameter, tensile strength (if not specified, refers to maximum tensile strength)

TDI
Curing agent, tolylene 2,4-diisocyanate

TMETN
Energetic plasticizer, trimethylolethane trinitrate

UFAP
Oxidizer, ultrafine ammonium perchlorate, <5μ
I. INTRODUCTION (U)

This is the third semiannual Technical Report submitted in partial fulfillment of the requirements of contract F04611-72-C-0046. The technical portion of this report covers the period 1 March 1973 to 31 August 1973. Dr. L. J. Rosen is Technical Director of the Program and Dr. A. J. Di Milo is the Principal Investigator.

II. OBJECTIVE (U)

The initial objective of this technical effort was the demonstration of the potential of the energetic prepolymer PCDE in highly aluminized solid propellants containing high-energy nitrato- and nitro-plasticizers, ammonium perchlorate and/or HMX. The demonstration required formulation and scale-up of two propellants, one with Class 7 and one with Class 2 hazard characteristics. Scale-up was to culminate in preparation of 5-gallon batches and 15-lb BATES grains of each formulation. Characterization of mechanical properties, aging capability, and sensitivity was required in the course of achieving overall objectives.

An add-on program increased the scope of work involving the Class 2 propellant without changing the objectives of the program concerned with the development of the Class 7 propellant.

The overall objective of the add-on program is the development of a high-performance solid propellant for air-launched missiles based on PCDE prepolymer plasticized with a combination of BDNPA and BDNPF, and demonstration of the performance of this propellant by large-scale motor firings.

The propellant property goals are:

- A minimum delivered specific impulse of 250 lbf-sec/lbm.
- A minimum density of 0.068 lb/cu in.
- Propellant detonability no greater than that of a Class 2 explosive.
A burning rate of 1.6 with a range from 1.2 to 2.1 in./sec at 1000 psia, a pressure exponent at or below 0.5 and $\pi_k \leq 0.15\%/^\circ F$.

Better than the minimum target uniaxial mechanical properties ($\sigma_m = 100$ psi, $\epsilon_m = 30\%$ and $E_o = 500$ psi).

- Adequate aging stability.
- Adequate processing and cure properties.
- Safe manufacturing, handling and use characteristics.
- Adequate liner-bond properties.
- Adequate combustion-stability characteristics.
- High reproducibility.

III. SCOPE (U)

The augmented program adds three phases to the two phases of the original program.

In Phase II, motor performance tradeoffs necessary to attain ballistic objectives will be completed. The selected formulation will be evaluated and determined to be Class 2. The Phase II candidate propellant will be scaled up to 5-gal mixes and a total of six 15-lb BATES motors will be prepared and delivered to AFRPL. Three of these six motors will constitute an increase in the scope of this phase.

Work on the add-on program was initiated in Phase III in January 1973. In this phase, the burning rate of PCDE-BDNPa/F shall be tailored to provide a target burning rate of 1.6 in./sec at 1000 psia and formulations with burning rates of from 1.2 to 2.1 in./sec at 1000 psia will be identified. Additional goals include a pressure exponent of less than 0.5 and a $\pi_k$ of 0.15%/^\circ F.

Variables such as mix viscosity, pot life, viscosity versus time and shear rate or stress, bonding agents, curing agent, and cure catalyst will be assessed for their effect on processability, castability, and associated hazards.
Also in Phase III will be a systematic program of mechanical property tailoring and testing and propellant aging. Target properties will exceed $\sigma_m 100$ psi, $\epsilon_m 30\%$, and $E_o 500$ psi. Properties under multiaxial stress conditions will also be investigated, as will effects of temperatures of -65° to 180°F on mechanical properties. Aging studies of the propellant will also be initiated, and use of stabilizers and combinations of stabilizers to improve aging will be investigated. A compatible liner system will be developed.

Based on burning rate tailoring, processing and mechanical properties studies, selected formulation(s) will be scaled up to 5- and 30-gal mixes for further characterization of ballistic and mechanical properties and aging stability. Ballistic test motors of 10- and 70-lb charge will be fired over a pressure range of 500 to 3000 psia. Propellant from these batches will be placed in storage for periodic testing to the end of the program. Additional 70-lb BATES grains and other samples will be delivered to AFRPL.

ICC (DOT) explosive classification will be determined for the candidate propellant. An analysis of the hazards involved and their application to large-size grains will be undertaken. As part of the hazards evaluation, tests of critical diameter will be performed.

In Phase IV a selected formulation will be scaled up to the 300-gal size. Three Genie motors with 300-lb grains and two instrumented analog motors will be prepared and shipped to AFRPL for testing. Samples of propellant will be placed in storage for testing in Phase V.

Phase V of the proposed program is a propellant shelf life study program. Ambient and accelerated aging of propellant and motor grains prepared during Phases III and IV will be undertaken. Visual examination for swelling and cracking, and periodic measurement of mechanical and bond properties and burning rate will be made on aging samples. Motor grains will be fired after aging. Preliminary system safety analysis will be conducted.
IV. SUMMARY (U)

(U) The following is a summary of the technical progress made during the period from 1 March 1973 to 31 August 1973.

(U) A. A total of 98 lb of PCDE has been received from Hercules, Inc. during the past six months. This material consisted of 13 lots. In addition, drums of Shell Lot 44 were also received to fulfill specific contract requirements. All the earlier lots are found to contain acetone by infrared analysis; the more recent lots have not yet been examined. The lots have averaged less than 10 lb per lot, and have thus required considerable labor to blend them into convenient-sized lots.

(U) B. PCDE Lots 6 and 8 were passed through molecular sieves and blended to create Lot 6+8. Because Shell Lot 44 was used up, experimental work was continued with Lot 6+8.

(U) C. The viscosity of BDNPA/F varies considerably with change of temperature, decreasing from 730 poise at 64°F to less than 20 at 140°F. These data are pertinent to processing studies which have begun.

(U) D. Both PCDE and its propellants evolve gases when aged. The gases are mainly HCN and CO₂, except in the case of PCDE-TMETN propellant which also evolves oxygen, nitrogen, and water.

(U) E. The antioxidant Neozone D interfered with the cure of PCDE-TMETN propellants. DNDPA + S was a satisfactory replacement. The cure reaction was speeded up by altering the FeAA:HAA:ZnO catalyst ratio from 0.03:0.09:0.10 to 0.02:0.02:0.20.

(U) F. At higher temperatures the friction sensitivity of PCDE-TMETN propellants decreases while the impact sensitivity increases. At the processing temperature of 125°F, the propellant is safe enough to allow direct manipulation. The cured propellant is Military Class 7 and DOT Class A.

(U) G. Early 1-gal batches of PCDE-TMETN propellant contained unacceptable amounts of porosity, caused principally by impurities in the PCDE;
moisture in the HMX and AP had an additional minor effect. The PCDE impurities could be removed by passing the prepolymer through molecular sieves. By the use of this method, three 1-gal batches were made from which were cast 14 R&H 2C1.5-4 grains and samples for aging and hazards studies.

H. Three 5-gal batches of the propellant were prepared. These allowed preparation of five 15-lb BATES grains and aging samples for the Lockheed Propulsion Company. Although the grains were satisfactory, the aging samples had numerous colored inclusions which were the nuclei of larger areas of poorly cured propellant. Emission and infrared analysis of these inclusions indicated the presence of higher than normal amounts of Zn, FeAA, and DNDPA. It was concluded that these materials were not properly dispersed in the batch in question and that the Zn in the form of ZnO affected the cure. Future batches of this propellant will require attention to the need for properly dispersing these additives.

I. The strand burning rate of the PCDE-TMETN propellant was 0.466 in./sec at 1000 psia with a pressure exponent of 0.60. Twelve R&H 2C1.5-4 grains fired at AFRPL gave a burning rate of 0.49 in./sec with a pressure exponent of 0.53. Three of the 15-lb BATES grains have been successfully fired at AFRPL.

J. PCDE-TMETN propellant aged at 150°F fissured seriously after 1 week. At 110°F with exposure to the ambient atmosphere or sealed in cans, the propellant essentially retained its mechanical capability after 8 weeks. Sealed in cans at 110°F, the propellant exhibited increased friction sensitivity after eight weeks, and the same was true for propellant stored at 150°F for six weeks. Burning rate decreased very slightly for propellants aged at all conditions, but the change may be too small to be significant.

K. Iron oxide, copper chromite, and both 1μ and 3μ AP have been used to increase the burning rate of PCDE-BDNPA/F propellants. Copper chromite interfered with the cure of the propellant and no useful data
were obtained. The use of iron oxide will allow the target burning rate, 1.3 in./sec at 1000 psia, to be achieved with a pressure exponent of 0.6. The target burning rate could be obtained also with use of 1µ and 3µ AP. Recent work has uncovered some problem areas in that earlier burn rates could not be duplicated. The effect is believed to be the result of either variable UFAP quality or inefficient dispersal of the oxidizer in the recent experiment. Studies have been planned to provide clarification.

L. UFAP has been used to cure PCDE-BDNPA/F propellants. Good mechanical properties were achieved along with increased potlife provided by the slower-curing IPDI.

M. Initial stabilizer studies are inconclusive; none of the stabilized propellants exhibits much difference in weight loss at 150°F compared to the unstabilized propellant. Di-t-butylresorcinol interfered with propellant curing. Santicizer 8 has the advantage of being liquid.

N. Although earlier work with the PCDE-BDNPA/F system relied on a coated AP, experiments showed that adequate mechanical properties are obtained with uncoated oxidizer and DEA as bonding agent. Current work is being done with uncoated AP and DEA.

O. Because Shell PCDE Lot 44 was used up, Hercules PCDE Lot 6+8 is now being used. NCO and crosslinker requirements have been determined. The observation has been made that MDX-65 aluminum cures better than H-60 in these formulations. The effect is not due to interaction between the aluminums and the curing agent, but the cause is still unknown. The potlife of the propellants exceed four hours, the longest measurement made.
V. TECHNICAL DISCUSSION (U)

A. PCDE ACQUISITION (U)

A total of 38.06 lb of PCDE in 9 lots was received from Hercules, Inc. in March 1973. Pertinent information for these materials is shown in Table 1. Lot 15 was received from Hercules in July 1973. The lot consists of 20.13 lb of PCDE. Properties reported by the vendor are listed below.

A further shipment of 39.9 lb of PCDE was received from Hercules Incorporated in August 1973. The shipment consisted of 0.99 lb Lot 16A, 19.3 lb Lot 17B and 19.6 lb Lot 18. No analytical data are available.

The PCDE (Lot 44) necessary for the 5-gal batches of PCDE-TMETN propellant was obtained from RPL. The PCDE was passed through molecular sieves until IR inspection indicated the absence of acetone. An additional amount of PCDE received was also treated as above. This material was used to prepare another 5-gal batch from which were cast three 15-lb BATES grains. Two grains made from earlier batch were topped. All five motors were delivered to AFRPL.

f - Evolved gas exceeded syringe volume; test limited to 141 hours
UNCLASSIFIED

(U) The following comments concerning these shipments are of considerable importance to the program. First, in view of the time required to qualify a lot of PCDE for use in current formulations (3 weeks), the number of lots corresponding to the total amount of PCDE received is a disadvantage. This handicap can be reduced, but not completely eliminated, by blending to provide larger lots. It should be understood, however, that blending involves the danger that considerable amounts of material might be irrevocably lost if one or more of the lots used for blending are exceptionally bad. It is recommended that the blending operations be performed by the supplier and that data for the lots blended be furnished.

(U) The lots received are in very dilute solutions, some as low as 3%. This entails shipping and handling of excessive amounts of containers and solvent. It is recommended that attempts be made to maintain the PCDE concentration at 20% or higher to avoid these problems.

B. INGREDIENTS STUDIES (U)

1. PCDE Lot 6+8 (U)

(U) Qualification of PCDE received from Hercules, Inc. was initiated. Figure 1 is an infrared scan of as-received Lot 6. The characteristic band for acetone is clearly visible at 1720 cm$^{-1}$. This band was also present in the scan for Lot 8. Lots 6 (9.6 lb) and 8 (2.57 lb) were reduced in volume after passing through 13X molecular sieves and combined. Data for the lots and the derived averages for the combination are given in the Table below.

* Volume of gas from 0.25 gm PCDE at 110°C for 200 hr in 10 cc syringe.

The mixed lot was evaluated for NCO to OH ratio for cure and for PCDE to HT ratio for best mechanical properties in PCDE-BDNPA/F propellants and the results are described in Section V.E.7.

2. Viscosity of BDNPA/F (U)

Because PCDE-BDNPA/F propellants are highly viscous, a study was made of the effect of temperature on viscosity of BDNPA/F. The data are shown graphically in Figure 2.

There is a considerable advantage to using BDNPA/F at 140°F. The viscosity decreases from 730 poises at 64°F to less than 20 at 140°F. This information will be useful for process studies.

C. GAS ANALYSIS (U)

Because the odor of HCN has been frequently detected and HCN qualitatively identified in gases over PCDE and its propellants, an analysis of gases evolved from PCDE and its propellants on aging was made. The results are shown in Table 2 in which is also shown the fluoride ion (HF) content of the materials. Fluoride content, however, is confusing. In PCDE, itself, there is indication of enough fluoride ion to convert about 0.015 wt% FeAA to FeF₃, a serious interference. On the other hand, fluoride ion is also found in the propellants; either the analysis is in error or the fluoride ion does not react with FeAA.

a - Gas evolved consisted of 47.1 mol % of unidentified gases probably a mixture of acetaldehyde, formaldehyde, and oxides of nitrogen
b - Measured before aging
c - Volume per gram of sample
d - Not measured
The amount of gas evolved from PCDE or its propellants is very moderate. If the presence of solvent molecules in the gas is ignored, HCN and carbon dioxide are the chief constituents except in the case of the PCDE-TMETN propellant. In the latter, oxygen, nitrogen, and water are also found. No HNF₂ was detected.

D. PCDE-TMETN PROPELLANT STUDIES (U)

1. Introduction (U)

A comprehensive discussion of the thermodynamic rationale determining the choice of propellant compositions to be studied was presented earlier (1) and will not be repeated here. However, Table 3 is presented to make the reader aware of some of the possible formulations.

On the basis of these considerations, the baseline composition selected for the Class 7 propellant studies and scale-up was fixed at 79 wt% solids, 18 wt% aluminum, an HMX to AP wt ratio of 2 and a plasticizer to crosslinked polymer ratio of 1. The reasons for these choices are that (1) other compositions which can be processed would provide only a marginal increase in specific impulse and (2) the volume fraction of the binder (<0.27) is conducive to achieving adequate processability, mechanical properties and aging stability. Table 3 presents the background for establishing the baseline composition.

2. Effect of Neozone D on Cure (U)

Cure failure in 1-gal batches of PCDE-TMETN propellant was attributed to Neozone D, an antioxidant. A number of 450-g batches were made to test this idea and to obtain viscosity data for new formulations under consideration. These batches are shown in Table 4. PCDE 1-78 and -79 containing Neozone D did not cure at 110° or 125°F although the corresponding batches, PCDE 1-82 and -83, containing DNDPA + S, cured without difficulty. PCDE 1-83 had only 0.01 wt% FeAA and was definitely softer than PCDE 1-82 with 0.02 wt% FeAA. The latter two propellants were also made in 100-g batches, PCDE 228 and 229, which also cured well.

As a result of these experiments, a mixture of DNDPA + S was used in place of Neozone D as stabilizer.

3. Propellant Processability (U)

To obtain more definitive data on processability, Rotovisko measurements were made of propellant viscosity. Because these measurements require larger amounts of propellant, batch size was scaled up to 450g. The figure of merit for processability was taken as 50000 poise at a shear rate of 5000 dynes/cm².

Viscosity measurements were made on PCDE 1-80 through 1-83 (Table 3). The results are shown in Figures 3 through 6. All of the catalyst combinations used provide at least six hours of potlife. The catalyst system FeAA/HAA/ZnO at a ratio of 0.03:0.09:0.10 was used in the third 1-gal batch PCDE 10GP-9306, which cured very slowly. The slowness of the cure may have been due to the large amount of HAA used. Because it retards the cure reaction, the HAA must be removed before the FeAA can exert a catalytic effect. For subsequent 1-gal or larger batches, the FeAA/HAA/ZnO was limited to 0.02:0.02:0.10, as in PCDE 1-82.

4. Hazards Studies (U)

a. Introduction (U)

PCDE imposes a hazards problem greater than that imposed by more conventional propellants. The chief problem is their sensitivity to friction. Mixtures of PCDE and TMETN are not sensitive to friction even when they contain aluminum, but the addition of oxidizer increases the sensitivity of the propellant to friction. The uncured propellant is generally more sensitive than the cured. This friction sensitivity has required that caution be exercised in scaling-up propellant production. More extensive discussion of hazards was reported earlier.

b. Effect of Temperature (U)

The PCDE-TMETN propellant was tested at the preparation temperature, 125°F. The first attempt indicated that the friction sensitivity was much less at this temperature. In fact, the propellant was negative even at 4000g/3000 rpm with one PCDE lot. On the other hand, the impact stability was decreased from 13 to about 4 cm/2 kg. Another test was made which generally confirmed the earlier tests. In the second test the impact sensitivity at 125°F was just above 6 cm/2 kg. At 125°F, the propellant is Aerojet Type 3D and remote casting is unnecessary. However, at lower temperatures, precautions are necessary.

The data are reviewed in Table 5.

c. DOT Tests (U)

PCDE-TMETN propellant, PCDE 10-4 (10GP9622), was subjected to hazards testing to establish its DOT classification. It is DOT Class A and Military Type 7. The tests and results are summarized in the table below.

5. **1-Gal Batches (U)**

a. Batch 10GP9002 (PCDE 10-2) (U)

Because the first 1-gal batch, 10GP8798 (10-1), had an unacceptably high porosity, a second batch (10GP9002, 10-2) was made with the formulation being modified in two ways. The catalyst system of FeAA-HAA-ZnO was substituted for DBTDL-benzilic acid-ZnO, and Neozone D was used in place of DNDPA + S. The composition of the batch is shown in Table 6. This batch did not cure.

b. Batch 10GP9306 (PCDE 10-3) (U)

It became apparent on further examination of data for 450-g batches that these propellants do not cure as well with Neozone D as they do with DNDPA + S. Data to substantiate this were presented in Section V.D.2. Accordingly, a third batch, 10GP9306 (10-3), was formulated in which the Neozone D was removed and DNDPA + S was used in its place. The composition of this batch is also given in Table 6. This batch cured very slowly, taking almost 7 days at 110°F to reach measureable Shore "A" hardness. At 125°F, however, it cured more rapidly. Inspection of one container of propellant indicated that it contained a high degree of porosity.

c. Batches 10GP9622 and 9663 (PCDE 10-4 and 5) (U)

Batch 10-3 (10GP9306), a 1-gal batch prepared earlier in the program, cured very slowly, requiring over 7 days to achieve a measurable hardness. The slow cure was due to the large quantities of the catalyst suppressor, HAA, used. The batch contained 0.03 wt% FeAA and 0.09 wt% HAA. Experiments were made, therefore, to reduce both the FeAA and HAA to obtain adequate potlife and quick reliable cure. A system consisting of 0.02 wt% FeAA and 0.02 wt% HAA appeared to be promising; FeAA, 0.01 wt%, and HAA, 0.01 wt%, gave a much softer cure.

\(^a\) - Passed through molecular sieves  
\(^b\) - Equivalents ratio, PCDE/HT/IPDI = 55/45/100
The former system provides a potlife of six hours (Section V.D.3., Table 4, PCDE 1-82 and 83) and was used in the 1-lb Batches 1-84 through 87 and 1-gal Batches 10-4 through 6. All cured in three to four days at 125°F. The composition and properties of these small batches are shown in Table 7.

(2) Causes of Propellant Porosity (U)

Studies relating to porosity in 1-gal batches of PCDE-THETN propellants were made at the 1-lb level. Four propellants, shown in Table 8, were made according to the variations indicated in the table. Considerable porosity was observed in PCDE 1-84 for which the PCDE has been passed only once through molecular sieves and the solids had received only normal drying. When PCDE was passed twice through the sieve column, as for PCDE 1-85, the porosity was reduced greatly even though the solids were only normally dried. Only negligible porosity was found in PCDE 1-86 and 87, both of which utilized PCDE that had passed through the sieves twice and solids that had undergone extra drying.

The important effect of the special sieve treatment is apparent in considering the very low 24-hr hardness value of Batch 1-84. The batch actually never achieved the extent of cure of the others. It may not be necessary to pass PCDE through sieves twice, but rather to increase the ratio of sieves to PCDE for a given pass. It was noted by infrared analysis of effluents from the sieve column that although the material coming through first was free of the 1730 cm⁻¹ band, the material coming through last showed the band, indicating acetone contamination and the need to investigate the effect of sieves to raw material ratio.

The 1-lb batches were vacuum-cast to diminish the possibility of void formation resulting from that operation and to pin-point the actual cause.

(3) 1-Gal Mixes (U)

In early scale-up batches, PCDE-TMETN propellant cured with unacceptable levels of porosity. In subsequent studies of the effects of PCDE pretreatment, extra drying of solids and mix cycle made with 1-lb batches, the porosity was found to be caused mainly by insufficient pretreatment of PCDE. Dryness of the solids was a less important factor. Details of these studies were given in the previous section.

Based on these results, PCDE was passed twice through molecular sieves and solids were all dried for twenty four hours before use in 1-gal batches. One batch, PCDE 10-5 (10GP9663), differed from the other, PCDE 10-4 (10GP9622), in being mixed for twenty minutes in vacuum after NCO addition rather than the ten minutes used in the usual procedure. Although this change in mix time may have little or no bearing on the question of porosity, the longer mix time resulted in greater fluidity. The formulations and some of their properties are shown in Table 9.

d. Batch 10GP9710 (PCDE 10-6) (U)

Because the tensile strength of PCDE 10-5 was somewhat low, the formulation was modified by the addition of more HT. The modified formulation, PCDE 10-6 (10GP9710), was prepared and cast into fourteen 1/4-lb motors. The propellant cured well, and the motors were shipped to RPL. The composition and properties of the propellant are shown in Table 9.

6. 5-Gal Batches (U)

a. Batch 73-05-130 (U)

The PCDE-TMETN candidate propellant was prepared on a 5-gal scale. The composition of the batch, PCDE 60-1 (Batch No. 73-05-130), is shown in Table 10. The mixing of the batch presented no problems, but difficulties were experienced with special casting apparatus designed for

a - PCDE and TMETN passed through molecular sieves. Equivalents ratio, PCDE/HT/IPDI/TDI = 53/47/100/0 and 53/47/100/2 for PCDE 1-88 and 60-1, respectively.

b - Batch No. 73-05-130
remote operation. BATES motors cast by this method showed a large slump when the surrounding atmospheric pressure was increased from 2" to 15" of mercury. The slump indicates that propellant castability was poor and voids, which collapsed under atmospheric pressure, were trapped in the motors. On the other hand, the castability of the propellant has been measured and is considered adequate at 125°F. For these reasons, the poorer flow encountered in the scale-up batch was probably due to the failure to keep the propellant at 125°F during casting or to cooling of the propellant before release of the vacuum. Cooling of the propellant could make it rigid enough to successfully resist collapse around voids even at one atmosphere pressure.

(U) Subsequent x-ray photographs of the BATES grains indicated small voids in one of them; the others were free of voids and could be salvaged. During the casting which required six and a half hours, the propellant was constantly mixed.

(C) A carton of this propellant cured to a hardness of 24 Shore A, which is low for this propellant. The long mixing may have stripped the coating from the AP and HMX causing a lower state of cure. Two strands of the propellant were burned to determine if the burning rate had been affected. The burning rate, 0.484 in./sec at 1000 psia, compared favorably with that of 0.464 obtained from a 1-gal batch of propellant.

(U) Scale-up to 5-gal required the use of a new lot of coated AP. A preliminary 1-lb batch was made to test the effect of the new lot. The formulation, PCDE 1-88, is given in Table 10. It should be noted that this propellant is Type 3 in the Aerojet hazards classification. The propellant exhibited a Shore A hardness of 31 in four days, which was somewhat low for this propellant. In order to compensate, 2 eq.% TDI was added to the scale-up propellant formulation. TDI was added because the previous lot of AP had been TDI-coated, whereas the new lot was coated with HDI. (After seven days, PCDE 1-88 did attain a hardness of 53.)
b. Batch 73-05-151 (PCDE 60-2) (U)

Another 5-gal batch of propellant was made to provide aging samples for the Lockheed Propulsion Company. The batch mixed well and was cast manually because the propellant was shown to be Aerojet Type 3D at 125°F, see Section V.D.4.b. Fourteen elliptical cylinders and a 12 x 3-1/2 x 3-1/2" block were cast in vacuo, and a block was spatula cast from the propellant in the lines. All cured satisfactorily in one week at 125°F.

The compositions and properties of the propellants are shown in Table 11. TDI, 2 eq.%, had been added to PCDE 60-1 because previous lots of AP used in the propellant had this isocyanate in the coating. The coated AP used in PCDE No. 60-1 had HDI instead of TDI in the coating. When it was discovered that the hardness of PCDE 60-1 was low, it was not tested mechanically, but instead the subsequent batch, PCDE No. 60-2, was made without the TDI and with more crosslinker to ensure a higher modulus.

Colored inclusions which were the nuclei of larger uncurled spots were observed in PCDE-TMETN propellant shipped to the Lockheed Propulsion Company. The inclusions, subjected to analysis by emission and infrared spectroscopy, contained high concentrations of Zn, FeAA and DNDPA. The Zn was very high and, in fact, none was found in the propellant proper. The FeAA concentration was only slightly higher in the inclusions. FeAA, ZnO and DNDPA are added together to the liquid fuel before propellant mixing and the ingredients dispersed by manual agitation. This procedure worked well in the 5-gal batches, 73-05-130 and -161. Henceforth, however, it would seem advisable to add the mixture of solids slowly with mechanical agitation to ensure dispersal of the ZnO. While the exact nature of the reactions occurring are not known, it is believed that the high concentration of basic ZnO could deplete the surrounding area of isocyanate and prevent adequate cure.

c. Batch 73-05-161 (PCDE 60-3) (U)

A third 5-gal batch of PCDE-TMETN propellant was made; its composition, shown in Table 12, is the same as the second one. Three 15-lb BATES grains were cast from the batch, and two BATES grains, which had been cast earlier, but slumped, were topped. The propellant cured to a hardness of 52 (Shore A) in seven days at 125°F.

The BATES grains were x-rayed and sent to AFRPL, including the grains which had been topped.

The table below shows the mechanical properties of the third 5-gal batch, PCDE No. 60-3 (73-05-161). The ambient tensile strength is about 70 psi instead of the target 80 psi. The low value is probably the result of a slight undercuring. It is observed in aging of this type of propellant that there is always an initial post cure.

7. Burning Rates and \( \pi_k \) (U)

Burning rates at -65, 80, and 150°F were obtained from the Propellant Batch 10GP9710 (PCDE 10-6), cast into 1/4-lb motors. The data are summarized in Figure 7. At 80°F and 1000 psia, the burning rate is 0.466 in./sec with a pressure exponent of 0.60. The value of \( \pi_k \) between -65° and 150°F is 0.2%/°F. These data were utilized to fire two 1/4-lb motors at Aerojet to provide information for expediting more extensive testing at AFRPL.

BURNING RATE OF PCDE-TMEX PROPELLANT AT -65, 80, and 150°F (ECOE 20-6, 10CP-9710) (U)

-37-

CONFIDENTIAL Figure 7
The solid strand burning rates of PCDE-TMETN Propellant 60-3 (Batch 73-05-161) were determined at ambient temperature from 500 to 3000 psig. The data are shown graphically in Figure 8. The burning rate, 0.456 in./sec at 1000 psia, and the pressure exponent, 0.61, are normal for this formulation.

8. Rohm & Hass 2Cl.5-4 Propellant Grains (U)

Table 13 gives weight data for 2Cl.5-4 motors delivered to AFRPL. Two additional motors were fired at ASPC. The specific impulse efficiencies were 90.11% and 89.26% at 1000 and 800 psia, respectively. The data are given in Table 14.

The burning rates obtained from these motor firings, 0.444 and 0.530 in./sec at 826 and 1063 psia, respectively, are higher than the rates expected from solid strand data (see previous section) and they give a higher pressure exponent, 0.70, than do the solid strands. The number of motors tested, however, is too small for firm conclusions.

Firing traces for the two motor tests are shown in Figures 9 and 10.

Figure 11 shows the burning rate vs pressure relationship reported by AFRPL on the basis of 12 firings of R & H 2Cl.5-4 motors. They report the burning rate at 1000 psia to be 0.49 in./sec with a pressure exponent of 0.53.

9. Aging Stability (U)

a. Introduction (U)

A 1-gal batch of PCDE-TMETN propellant, PCDE 10-5 (10GP9663), was subjected to aging at 110°F, exposed to the atmosphere or sealed in a friction-top tin can, and 150°F. After two weeks at 150°F, the 2 in. propellant cubes had fissured seriously. No mechanical property data were obtained on these samples, but safety data were obtained. Other data for storage at 77° and 110°F are shown in Table 15.

\textsuperscript{a} PCDE No. 10-5 (Batch 10GP9663) aged as 2-in. cubes
\textsuperscript{b} Sealed specimens in closed friction-top tin can
\textsuperscript{c} Minibone specimen
b. Mechanical Properties (U)

The mechanical properties of propellant exposed at 80°F were essentially unchanged after 12 weeks. At 110°F, however, these properties improved, if anything, after two weeks and remained unchanged through the eighth week. In sealed-can aging at 110°F, improvement resulted after two weeks, but thereafter there was a slight hardening with time. After eight weeks, the propellant still has very useful properties.

c. Safety Properties (U)

Open exposure does not change the safety properties of the propellant even after 8 weeks at 110°F or 12 weeks at 77°F. When sealed at 110°F for eight weeks, the propellant shows only a greater sensitivity to friction. However, only one datum is available and further testing would be required to establish a clear-cut trend. A similar effect is observed with open exposure at 150°F, but the change of friction sensitivity is more pronounced in this case.

d. Burning Rates (U)

Apparently, there is a small decrease of the burning rate with time in those samples which remain exposed. This may indicate a small loss of plasticizer because the effect is not observed in specimens which were kept in sealed cans. More data would be required to establish the significance of the small change observed.

E. PCDE-BDNPA/F PROPELLANT STUDIES (U)

1. Introduction (U)

Table 16 presents calculated performance potentials of all-AP propellants suitable for a Class 2 requirements. The data in Table 16, representing the more optimistic prediction of efficiency, indicate that an all-AP propellant could deliver 250.8 lbf/lbm/sec at a density of 0.068 lb/in.\(^3\). Such a propellant would contain 51 wt% AP and 22 wt% Al. The current baseline composition contains, therefore, 51 wt% AP, 22 wt% aluminum, and a 1/1 ratio of BDNPA/F plasticizer to the crosslinked PCDE polymer.

**b** Figure of merit which includes effect of density.
2. **Burning Rates (U)**

   a. **Effect of Iron Oxide and UFAP (U)**

   (C) A burning rate of 1.6 in./sec was achieved earlier\(^1\) by incorporating 15 wt% 0.5µ AP into the PCDE-BDNPA/F baseline propellant, but only at the expense of increasing the pressure exponent to 0.75. In efforts to lower the exponent, Fe\(_2\)O\(_3\) was used. This iron catalyst was selected because its catalytic effect is more pronounced at the lower than at the higher pressures. Also, because it accelerates burning, it might be possible to reduce the amount of 0.5µ AP required to achieve the target burning rate and, thereby, reduce the pressure exponent. The results are indicated in Tables 17 through 19 and are summarized in Figure 12.

   (C) In the absence of UFAP, 1.5 wt% iron oxide will give a burning rate of 1.26 in./sec, a rate just in the range of interest to AFRPL. For such propellants the pressure exponent is less than 0.5. The data seem to indicate that rates up to 1.3 in./sec with a pressure exponent of 0.6 may be obtained with 1.0 wt% iron oxide and 10 wt% 0.5µ AP. With 15 wt% fine oxidizer the pressure exponents are of the order of 0.7.

   (C) The burning rates achieved in this study are not as high as those obtained in an earlier study\(^1\) with UFAP. This is, however, due to the fact that the present studies were based on formulations having less 6µ AP than those of the earlier study. Thus, there is no conflict in the data. In fact, if one uses 10 wt% UFAP, as in the earlier formulations, with 1.0 wt% iron oxide, it may be possible to obtain a burning rate of 1.5 in./sec at a pressure exponent of about 0.65.

   b. **Effect of Copper Chromite and UFAP (U)**

   (C) With the goal of achieving a burning rate of 1.6 in./sec at 1000 psia with a minimum of UFAP, copper chromite, a burning rate catalyst, was added to PCDE-BDNPA/F propellant. The results were generally poor; copper chromite interfered with the cure and caused gassing. No valid burning rates were obtained from this study, but the compositions of the propellants are shown in Tables 20 through 23 to indicate the extent of the study.

c. Effect of 1μ and 3μ AP (U)

(C) The burning rates of PCDE-BDNPA/F propellants with 1 and 3μ AP were determined and are reported in Tables 24 and 25 and Figures 13 through 16. With 3μ AP replacing all the 6μ AP and 15% of the 180μ AP, the burning rate at 1000 psia was 1.65 in./sec. Even higher rates, 1.83 in./sec, were achieved with 1μ AP in place of 6μ oxidizer. The pressure exponent increased as the 6μ oxidizer was replaced with the finer size.

d. Burning Rate Equation (U)

(C) The data on the burning rate of these propellants with 0.5, 1.0, and 3.0μ AP allowed derivation of equations for approximating the burning rate and pressure exponent of any combination of these materials in the PCDE-BDNPA/F baseline propellant. The equations are

\[ r_{1000} = 1.986x + 2.842y + 3.516w + 4.550v + 4.589z \]

\[ n = 1.722y + 1.894w + 2.667v + 2.867z \]

where x, y, w, v and z are the fractions of the propellant of 180, 6, 3, 1 and 0.5μ AP, respectively. The limited usefulness of these equations must be realized. They apply only to the baseline propellant, are based on a restricted sampling, have not been tested, and are intended only for guidance of formulation.

(C) Based on these equations, it was calculated that a formulation containing 28.33 wt% 180μ and 22.67 wt% 0.5μ AP would burn at 1.57 in./sec at a pressure exponent of 0.65. Propellants with various types of aluminum were made to test this prediction. The compositions are shown in Table 26. Solid strand data are shown in Table 26 and Figure 17. Although some of the rates were high, the pressure exponents were too high to be practical.

e. Problem Area (U)

(C) The required burning rate, 1.3 in./sec at 1000 psia, had been achieved early in the program by replacing both 6μ and 180μ

BURNING RATES OF PCDE-BDNPA/F PROPELLANTS (U)

![Graph showing burning rates vs. pressure for different PCDE No.]

- PCDE No. 274
- PCDE No. 275
- PCDE No. 276

Figure 17
AP with 5 wt% of 0.5 μm oxidizer. Such a formulation is difficult to process owing to the poor balance of small and large particle sizes. The burning rate had been attained with H-60 aluminum. Propellant with this aluminum has exhibited poorer cures than that containing MDX-65, which gives lower burning rates (see Table 26). A series of propellants was made, therefore, to determine the burning rates obtainable with MDX-65, H-60 and H-95 aluminum. The results of the study were not conclusive.

The composition and properties of the propellants are shown in Tables 27 through 29 and the burning rates are plotted in Figure 18. It is apparent that the burning rates are lower than were obtained earlier without the use of 0.5 μm AP; (see PCDE 212, Table 17) i.e. about 0.97 in./sec at 1000 psia. Except for the series containing the H-95, the burning rate changes very little with increasing UFAP. Moreover, even with 10% of 0.5 μm AP the pressure exponent is no higher than about 0.5. Contrary to reports by others, the highest burning rates were obtained with MDX-65.

Clarification of these data are required and work is in progress to determine whether the problem is the result of UFAP which has agglomerated, a mix cycle which is too short to allow adequate dispersal of the solids, or a characteristic of PCDE Lot 6+8 which was used to prepare the test propellants.

3. IPDI-Cured Propellants

IPDI which was instrumental in extending the potlife of PCDE-TMN propellants was investigated for this same purpose in PCDE-BDNPA/F propellants. The first propellants made (Table 30) did not cure. The Neozone D in these propellants was the cause; similar behavior was observed with the PCDE-TMN system (Section V.D.2). A second series of

<sup>c</sup> - Uncured

---

-71-
propellants was made without antioxidant and these cured well. The data (Table 31) indicate that the correct NCO to OH ratio is 1:1, but that the crosslinker content is low. In order to increase the moduli of the IPDI-cured propellants, a third set was made with the PCDE to HT ratio fixed at 40 to 60 (Table 32). The results indicate that while the properties are good, some improvement might be made by lowering the HT content slightly. The third set did not show the maximum modulus at 100 equivalents percent NCO.

4. **Effect of Stabilizers (U)**

A study of stabilizers for PCDE-BDNPA/F propellants was made at the 100-g batch size. Sulphur, dinitrodiphenylamine (DNDPA), di-t-butylresorcinol (DBR), Santicizer-8, and combinations of these were tested. The compositions and properties of the propellants are indicated in Table 33. Aging of these was in sealed metal containers at 150°F. All samples containing DBR had lower than normal moduli because DBR interfered with cure.

The weight loss data indicate that except for DBR, which was worse, a combination of the other stabilizers are little different than the control with no added stabilizer. Because the propellant was viscous, it was decided to use the liquid Santicizer-8. Further studies will be made later to determine which stabilizer is best.

5. **Use of Uncoated AP and DEA (U)**

It was noted earlier in the program that good mechanical properties could be achieved with uncoated AP if DEA was used as a bonding agent. Propellants were made to test this effect as there would be an advantage to using uncoated AP. The propellant compositions and properties are tabulated in Table 34. The experiment worked well. DEA not only gave good properties with uncoated AP, but also allowed a decrease in the total crosslinker content. In view of these results, the use of coated AP was discontinued.

---

a - PCDE and BDNPA/F passed through molecular sieves. Equivalents ratio, PCDE/HT/DEA/TDI = 55/45/0/112, 55/30/15/112, 60/30/10/112, and 60/20/20/112 for PCDE 268 through 271, respectively.

b - Cured specimens for PCDE 268 and 270; uncured specimen for PCDE 271.
6. **PCDE to BDNPA/F Ratio (U)**

(U) The addition of BDNPA/F to PCDE lowers the performance of propellants containing the latter. For this reason, it is advantageous to increase the PCDE at the expense of the plasticizer. Such a course is of only limited utility, however, because it will tend to make processing more difficult. As no determination had been made of the effect of increased PCDE on processing, a series of propellants was made at PCDE to BDNPA/F ratios in the range of 1.0 to 1.31. The compositions of these propellants are given in Table 35. The processing of propellants made at ratios of 1.0 and 1.1 was very similar, but that of those made at ratios of 1.2 and 1.31 was noticeably more difficult. Subsequent preparation of PCDE-BDNPA/F propellants was made at a PCDE to BDNPA/F ratio of 1.1.

7. **PCDE Lot 6+8 (U)**

a. **Introduction (U)**

(U) Heretofore, all PCDE work was done with Shell Lot 44. Because this lot of material was used up, a new lot of PCDE was investigated. The lot was created by combining Hercules Lots 6 and 8. Pertinent data concerning these lots and their mixture are given in Section V.B.

b. **NCO Requirement (U)**

(U) A series of propellants was formulated to determine the optimum NCO to OH ratio for curing Lot 6+8 with IPDI. The NCO to OH ratio was varied from 0.80 to 1.30 in equal increments of 0.1. In this series, PCDE Nos. 281 through 286, propellants with NCO to OH ratios above 1.10 did not cure. Another overlapping series, PCDE Nos. 291 through 294, was made at NCO to OH ratios between 0.60 and 0.90. Propellants with NCO to OH ratio less than 0.80 did not cure. The second series which contained MDX-65 in place of H-60 aluminum cured better. The compositions and properties of the two series are presented in Table 36.

- **In all cases PCDE to HT ratio maintained at 40 to 60.**
- **Cured specimens**
- **Minibone specimens**
A plot of the propellant moduli vs the NCO to OH ratio for PCDE Nos. 281 through 286 (Figure 19) indicates the optimum ratio to be 0.95. The results of mechanical property testing of PCDE Nos. 291 through 294 are consistent with this ratio. Because the equivalent weight assumed for the formulation studies was 1511, the actual equivalent weight of the prepolymer (calculated from the optimum NCO/OH ratio) is 1586, which corresponds to a "true" optimum ratio of 1:1. For a molecular weight of 2821 the functionality of the material would be 1.78, if the true equivalent weight is 1586. This value is consistent with the results of crosslinker requirement studies.

c. Crosslinker Requirements (U)

(1) With HT (U)

With the NCO to OH ratio held at 0.85, a series of propellants (PCDE Nos. 287 through 290) was made with the PCDE to HT equivalents ratio being varied from 35/65 to 50/50. The compositions and properties of these are presented in Table 37. The results indicate that 60 to 65 eq% HT will be required to cure propellants with Lot 6+8. This large crosslinker requirement indicates poor functionality for the PCDE.

(2) Effect of Aluminum Type (U)

It was observed that those propellants which were formulated with MDX-65 cured to higher moduli than those which contained H-60. This can readily be seen from the data in Table 36; compare PCDE 281 with 293 and PCDE 282 with 294.

It was postulated that the difference might be due to some effect of the metal on the isocyanate. To test this postulate, MDX-65 and H-60 were stirred overnight with IPDI at ambient temperature. After filtration and drying, the aluminums were used in propellant along with untreated ones. The composition of the propellants and their mechanical properties are shown in Table 38.

<sup>a</sup> - Lot 6+8 PCDE and BDNPA/F passed through molecular sieves. Equivalents ratio, PCDE/IPDI = 45/55/95.

<sup>b</sup> - MDX-65, untreated

<sup>c</sup> - H-60, untreated

<sup>d</sup> - MDX-65, treated (see text)

<sup>e</sup> - H-60, treated (see text)
It is apparent that the propellants containing MDX-65, treated or untreated, are better cured than those containing H-60. The effect is, therefore, not the result of reactions involving aluminum and the isocyanate. Further experiments must be done to clarify the significance of the effect.

(3) With HT + DEA (U)

A series of propellants was made in which the crosslinker HT was replaced by DEA. The composition and properties of the propellants are given in Table 39. The properties of the propellants were generally good indicating that DEA should be used. PCDE Nos. 303, 304 and 305 have elongations adequate for the goals of this program. It should be noted that MDX-65 was used in these batches. Experience indicates that propellants using H-60 will require more crosslinker.

8. Processing (U)

Processing studies of PCDE-BDNPA/F propellants have begun. The effect of processing aids and of HAA content on the viscosity of the propellant has been investigated. The composition and viscosity of the propellants are recorded in Tables 40 and 41. Graphic representations are shown in Figures 20 through 27. The data presented are tentative in nature because the viscosity measurements were made in small tubes containing about 50-g of propellant. This procedure is, however, adequate as a screening method. Techniques or formulations that are promising will be investigated further by more reliable measurements.

The control propellant has a potlife in excess of four hours, the limit of the measurement. FC-189 decreases the potlife. On the other hand, P711, which is also an antioxidant, decreases propellant viscosity both at 5000 dynes/cm² and at infinite shear stress. The effect of DC-200 is difficult to assess. The propellant containing it has a lower viscosity at 5000 dynes/cm² at four hours than at two, because of the change of the viscosity-shear stress curve with time. At infinite shear stress, the viscosity of the DC-200 propellant is the same as that of the control.

PCDE No. 348
(hours after NCO addition)

Figure 26

Viscosity at 125°F, poise x 10^-3

Applied Shear Stress, dynes/cm² x 10^-3
If the FeAA level is maintained at 0.05%, the best propellant viscosity is obtained with 0.03% HAA. With 0.05% HAA the viscosity is just a little higher. In both cases, the potlife exceeds four hours.

The processing studies are continuing, and improvements are being incorporated in the propellant formulation.
