ABSTRACT

Modifications of the basic balloon-shape equations are developed for cylinder and cylinder-end balloons, taper-tangent balloons, and tangent-harness balloons. Examples of the shape of these balloons are presented, and corresponding meridional stresses are determined. Zero and non-zero circumferential stresses are considered.

DETERMINATION OF THE SHAPE
OF A FREE BALLOON

Scientific Report No. 4

I. INTRODUCTION

In a previous report the general equations were developed for determining the shapes and stresses of axi-symmetric balloons. In succeeding reports examples of various balloon types were presented. In this report three additional types of balloons will be considered: 1) balloons with cylinder-end sections, including those completely cylindrical; 2) balloons with taper-tangent end sections; and 3) balloons with the payload attached by a tangent-cone harness.

II. GENERAL EQUATIONS AND SOLUTION

The general equations for the shape and stresses of a balloon are

\[
\frac{d\Theta}{ds} = \left[ t_c z' - w r r' - b r(z + a) \right]/(r t_m)
\]

\[
\frac{d(r t_m)}{ds} = t_c r' + w r z',
\]

and

\[ r' = \sin \Theta \]

\[ z' = \cos \Theta, \]

- 1 -
where the prime refers to differentiation with respect to gore position parameter \( s \). The symbols used throughout this report are defined in Appendix I.

The equations in (1) are derived respectively from summations of the forces normal and parallel to an elemental rectangular area of the balloon surface. These equations are restricted to balloons made from thin, flexible, inelastic material; they may be solved numerically by the Runge-Kutta method. The solution is started at the bottom of the balloon where the payload is attached. An estimate is made of the bottom apex angle. The initial meridional stress \( (t_m) \) is thereby determined, since

\[
 r_o t_m = \frac{L}{2\pi\cos \Theta_o}.
\]

The value of the circumferential stress \( (t_c) \) may be specified as desired. Values of the variables are determined by successively incrementing \( s \). The solution is complete when the balloon shape closes at the top.

Several methods have been presented\(^2,3\) for determining the balloon weight and volume. It has since been found that a superior method includes the differential expressions for weight and volume as part of the above set of simultaneous equations defining the balloon shape. The equations to be included are

\[
 \frac{dA}{ds} = 2\pi r
\]

\[
 \frac{dV}{ds} = \pi r^2 z'.
\]

As the total number of gore increments is increased, the volume and area converge to final values about as rapidly as the balloon coordinates converge.
III. MODIFIED EQUATIONS

A. Cylinder and Cylinder-End Balloons

Figure 1 shows what the shape of a cylinder-end balloon would be if all the material were fully deployed.

![Diagram of cylinder-end balloon](image)

Figure 1. Sketch of cylinder-end balloon with end sections opened

A cylinder balloon is treated as a cylinder-end balloon whose cylindrical portions meet. Except for the cylindrical portions, the balloon is fully tailored and has a constant material unit weight. The cylinder ends are treated as portions of a natural-shaped balloon which have a varying material unit weight. When \( r \) is less than \( r_0 \) (in Figure 1), the weight of an elemental circumferential band of width \((ds)\) is clearly

\[ w(2\pi r_0) \, ds. \]

(This weight and the expressions that follow are the same in the upper end section except that \( r_0 \) is replaced by \( r_1 \).)
Then the effective weight per unit area is

$$w(2\pi r_o') \frac{ds}{2\pi r \, ds} = w(r_o'/r).$$

By replacing $w$ in Equations (1), we have in the cylinder-end sections:

$$\frac{d\Theta}{ds} = \left[ t_c z' - w(r_o) r' - b r (z + a) \right] / (r t_m) \quad (1a)$$

$$\frac{d(r t_m)}{ds} = t_c r' + w(r_o) z'.$$

The form of $r'$, $z'$, and $\frac{dV}{ds}$ is unchanged, but the area equation becomes

$$\frac{dA}{ds} = 2\pi r_o.'$$

To find $r_o'$, it is necessary to specify the initial meridional stress $(t_m)$. The total film load is

$$T_o = L/\cos \Theta_o = 2\pi r_o t_m,$$

so

$$r_o = L/(2\pi t_m \cos \Theta_o).$$

The initial meridional stress is known from material strength considerations. As $s$ is being incremented, the stress will exceed its original value because of the material weight. When $r = r_o$, the shape equations revert to the form of Equations (1). Finally, when $t_m$ reaches a second predetermined value, Equations (1a) are used again with $r_o$ replaced by $r_1$. 

- 4 -
B. Taper-Tangent Balloons

As was the case for cylinder-end balloons, it is helpful to examine the shape of a taper-tangent balloon as if all the material were fully deployed (see Figure 2).

![Figure 2. Sketch of taper-tangent balloon with end sections opened](Note: \( s_0 = 0 \)]

In Figure 2, it is also clear that in the areas where there is fullness due to the taper-tangent end section, the weight of an elemental band of width (ds) is

\[
w(2\pi) \left[ r_O + (s - s_O) \sin \beta \right] ds.
\]

\( r_O \) and \( s_O \) are used in the lower end section; \( r_1 \) and \( s_1 \) are used in the upper end section.
The modified shape equations are then

\[ \frac{d\Theta}{ds} = \left[ t_c z' - w \left( r_o + (s - s_o) \sin \beta \right) r' - b r (z + a) \right] / (r t_m) \]  

\[ \frac{d(r t_m)}{ds} = t_c r' + w \left( r_o + (s - s_o) \sin \beta \right) z'. \]  

(1b)

The area equation is

\[ \frac{dA}{ds} = 2\pi \left( r_o + (s - s_o) \sin \beta \right). \]

Balloon shapes of this type are computed in much the same way as the balloon shapes of cylinder-end types. The angle \( \beta \) may be initially specified as zero. The actual value is then found by iterative trial and error. After \( r \) passes its maximum and after \( t_m \) reaches a specified value, \( \beta \) is set to equal \( \Theta \); \( r_o \) becomes \( r_1 \), \( s_o \) becomes \( s_1 \), and the shape equations used change from the form of Equations (1) to that of Equations (1b).

C. Tangent-Harness Balloon

In previous reports and up to this time, all payloads have been considered to be applied at the axis of symmetry. For the tangent-harness balloon, the payload is attached at a circumferential ring. There are several ways this can be done. The particular method we have chosen herein applies the payload tangentially. There is a discontinuity in meridional stress and in radius of curvature at the ring, but no discontinuity in the slope of the shape curve. The balloon is approximately spherical below that point. The method used to compute the balloon shape depends upon the circumferential stress. Two stress conditions are discussed below: meridional and circumferential stress equal; and circumferential stress equal to zero.
1. Meridional and Circumferential Stress Equal

If \( t_c = t_{m'} \), Equations (1) may be modified and simplified. By replacing \( t_c \) with \( t_{m'} \), the first of Equations (1) becomes

\[
\frac{d\Theta}{ds} = \frac{z' w' + b(z + a)}{r t_{m}}.
\]

If the left-hand side of the second of Equations (1) is differentiated,

\[
\frac{d(r t_{m})}{ds} = t_{m} r' + r t_{m}',
\]

and is set equal to the right-hand side, rearranged, and integrated, then

\[
t_{m} = w z + t_{m_{o}}.
\]

For initial values, note that at the bottom of the balloon, \( \Theta_{o} = 90^\circ \) and \( R_c = R_{m} \); then

\[
ba + w = \frac{t_{c} + t_{m}}{R_{c} R_{m}} = 2 \frac{t_{m_{o}}}{R_{m_{o}}};
\]

or initially,

\[
\frac{d\Theta}{ds} = \frac{-1}{R_{m_{o}}} = -\frac{ba + w}{2 \frac{t_{m_{o}}}{R_{m_{o}}}},
\]

where \( a, w, \) and \( t_{m_{o}} \) are specified.
During computation it is more convenient to use the differential form of $t_m$. Then,

$$\frac{d\Theta}{ds} = \frac{z'}{r} - \frac{w r' + b(z + a)}{t_m}$$

$$\frac{dt_m}{ds} = wz'.$$

These equations are integrated from the bottom upward until a specified payload attachment point is reached. At that point $t_m$ is increased by $L/(2\pi r \cos \theta)$.

The computation is continued until the balloon closes at the top. To yield a flat-topped balloon, the proper $a$, $t_m$, and harness attachment for a given $w$ are found by trial and error.

2. **Circumferential Stress Equal to Zero**

If $t_c = 0$, Equations (1) become

$$\frac{d\Theta}{ds} = -\left[\frac{w r' + b(z + a)}{t_m}\right]$$

$$\frac{d(r t_m)}{ds} = wz'.$$

Note that this case is not quite as 'simple' as the case where $t_c = t_m'$ because the second equation does not now integrate directly. The initial value of $\frac{d\Theta}{ds}$ is

$$-\frac{w + ba}{t m_o}.$$
Note that this value is twice as large as the initial value when \( t_c = t_m \). The initial values of \( \frac{d(r t_m)}{ds} \) and \( r t_m \) are zero.

By differentiating \( r t_m \),

\[
\frac{d(r t_m)}{ds} = r't_m + r t_m'.
\]

we see that

\[
t_m' = w z' - \frac{r'm}{r} = w \cos \Theta - t_m (\sin \Theta)/r;
\]

and for \( t_m \) finite,

\[
\lim_{r \to 0} t_m' \to -\infty \text{ at the bottom}
\]

\[
\lim_{r \to \infty} t_m' \to +\infty \text{ at the top}.
\]

This result could have been anticipated from the previous findings for zero-circumferential stress, natural-shaped free balloons. At the top, not only \( t_m' \) but \( t_m \) approaches infinity, because \( r t_m \) at the top is finite when \( r = 0 \).

When these equations are used to find balloon shapes, observe certain precautions: First, it is not possible to start at the top or the bottom and use Equation (2) because of its infinite character. Therefore, it is necessary to use Equations (1d). Secondly, at each point on the balloon there must be correspondence between \( r t_m \) and \( t_m \). If \( t_{m_o} \) is finite, \( r t_{m_o} \) is zero. At the outset \( r t_m \) will change very little; during the numerical evaluation \( t_m \) will tend to be a very small value rather than the specified value \( t_{m_o} \). This will cause \( d\Theta/ds \) to be unrealistically large. However, by initializing \( r t_m \) at an arbitrary finite value, the numerical
integration will proceed smoothly. This amounts to specifying \( t_m \) at a small but non-zero radius \( r \); \( t_m \) will now be infinite at the bottom when \( r = 0 \).

For the balloon designs which would use the tangent-harness concept, it is not desirable to use the material fullness and special end fittings required to accommodate the extra-high stress. Therefore, the shapes of such balloons, where \( t_c = 0 \), will not be presented.

IV. NON-DIMENSIONAL EQUATIONS

The equations in Section III are most easily used by reducing them to non-dimensional form. This is done by using the proper combinations of \( b \) (the unit buoyancy of the lifting gas) and \( \lambda \) (a length proportional to the volume of gas required to lift the payload alone). The results will then be independent of the altitude, the lifting gas used, and the payload. The non-dimensional equations are listed in Table 1 and the symbols are defined in Appendix I. The differential equation for volume is

\[
\frac{d}{d\sigma} \left( \frac{V}{\lambda} \right) = \pi \rho L^2 \xi'.
\]

Volume and weight are related:

\[
bV = P + W
\]

or

\[
\frac{V}{\lambda} = 1 + \frac{W}{P}.
\]

The weight is

\[
\frac{W}{P} = k \Sigma \left( A/\lambda^2 \right).
\]

Remember that the area used for balloon weight is the surface area of the balloon material—not the area developed by rotation of the balloon shape.
Table 1. Non-Dimensional Forms of the Balloon Shape and Area Equations

Fully Tailored Part

\[
\frac{d\theta}{d\sigma} = \left[ \tau \xi' - k \sum \xi_s' - \xi (\xi + \alpha) \right] / (\xi \tau_m)
\]

\[
\frac{d(\xi \tau_m)}{d\sigma} = \tau \xi' + k \sum \xi_s \xi'
\]

\[
\frac{d}{d\sigma} \left( \frac{A^2}{\lambda} \right) = 2\pi \xi
\]

Cylinder-End Part

\[
\frac{d\theta}{d\sigma} = \left[ \tau \xi' - k \sum \xi_s \xi' - \xi (\xi + \alpha) \right] / (\xi \tau_m)
\]

\[
\frac{d(\xi \tau_m)}{d\sigma} = \tau \xi' + k \sum \xi_s \xi'
\]

\[
\frac{d}{d\sigma} \left( \frac{A^2}{\lambda} \right) = 2\pi \xi_s
\]

Taper-Tangent-End Part

\[
\frac{d\theta}{d\sigma} = \left[ \tau \xi' - k \sum \left\{ \xi_s + (\sigma - \sigma_0) \sin \beta \right\} \xi' - \xi (\xi + \alpha) \right] / (\xi \tau_m)
\]

\[
\frac{d(\xi \tau_m)}{d\sigma} = \tau \xi' + k \sum \left\{ \xi_s + (\sigma - \sigma_0) \sin \beta \right\} \xi'
\]

\[
\frac{d}{d\sigma} \left( \frac{A^2}{\lambda} \right) = 2\pi \left\{ \xi_s + (\sigma - \sigma_0) \sin \beta \right\}.
\]

*Note: In this table, \( \xi' = \sin \theta \) and \( \xi \ = \cos \theta \).
Table 1. Non-Dimensional Forms of the Balloon Shape and Area Equations (Continued)

Tangent-Harness Design ($t_c = 0$)

\[
\frac{d\theta}{d\sigma} = - \frac{\sum \xi'\xi + \zeta + \alpha}{\gamma_m}
\]

\[
\frac{d(\xi \gamma_m)}{d\sigma} = k \sum \xi \xi'.
\]

Tangent-Harness Design ($t_c = t_m$)

\[
\frac{d\theta}{d\sigma} = \frac{\xi'}{\xi} - \frac{k \sum \xi'\xi + \xi + \alpha}{\gamma_m}
\]

\[
\frac{d\gamma_m}{d\sigma} = k \sum \xi'.
\]
V. RESULTS

A great deal of effort and computer time have been required to find solutions to the equations in Section IV. The existence of an equation does not imply the existence of a solution. In each case it has been possible to find solutions; but the search for the proper combination of parameters has been tedious and at times frustrating.

In the following paragraphs all the results are non-dimensional. When applying these or other previously tabulated results to an actual case, note the following: From the definition of $\Sigma$,

$$b = \frac{w}{k \Sigma \lambda}.$$  

From the definition of $\tau_m$,

$$b = \frac{t_{m_0}}{\tau_{m_0}} \lambda^2.$$  

By equating, we find that

$$\lambda = \left( \frac{k \Sigma}{\tau_{m_0}} \right) \left( \frac{t_{m_0}}{w} \right).$$

Since

$$p = b \lambda^3,$$

a load-altitude curve can be calculated for a given $\Sigma$, $\tau_{m_0}$, and $(t_{m_0}/w)$. For example, for polyethylene at 400 psi stress, $(t_{m_0}/w)$ is approximately constant at 987 feet for all sigmas.

In all cases one of the boundary conditions has been that the balloon shape must close with a horizontal tangent at the top.
A. Cylinder and Cylinder-End Balloons

1. Circumferential Stress Equal to Zero

Figure 3 shows the shape of a cylinder-end balloon when sigma varies and when the initial stress is constant. A value of \( \tau_m = 3.0 \) was chosen so a sigma as large as 1.0 could be used. For lesser values \( \tau_m = 1.0 \) there is no solution when sigma is as large as 1.0. Corresponding results for meridional stress are given in Figure 4. By comparing Figures 3 and 4 we can see that the shape changes at the top from fully tailored to cylindrical when \( \tau_m \) exceeds 3.0. This is an arbitrary value chosen to maintain approximately the same stress value in both cylindrical ends.

The effect of changing the initial meridional stress for a constant sigma is shown in Figures 5 and 6. The dashed lines show the shape of the cylinder ends. Again the change to a cylinder occurs at the top when the initial stress value is reached. For the example chosen \( \Sigma = 0.2 \) the balloon becomes a full cylinder when \( \tau_m \) is slightly larger than 0.4. When \( \tau_m = 0.4 \), the cylinder radius is greater than the maximum radius of the balloon shape; so in effect sigma is slightly larger than the initially specified value.

Gore lengths and weights of various cylinder-end balloons are shown in Figures 7, 8, and 9.
Figure 3. Shapes of balloons with cylindrical end sections and an initial stress value of 3.0 (Zero superpressure, zero circumferential stress)

(Note: The dots indicate the boundary between the cylinder-end and the fully tailored part.)
Figure 4. Meridional stress in cylinder-end balloons with an initial stress value of 3.0 (Zero superpressure, zero circumferential stress)
Figure 5. Shapes of balloons with cylindrical-end sections and varying initial stress
(Zero superpressure, zero circumferential stress, \( \Sigma = 0.2 \))

* (Note: The shape for \( \tau_{m_0} = 0.8 \) is omitted for clarity.)
Figure 6. Meridional stress in cylinder-end balloons with varying initial stress (Zero superpressure, zero circumferential stress, $\Sigma = 0.2$)
Figure 7. Gore length of cylinder-end balloons with various values of initial meridional stress  
(Zero superpressure, zero circumferential stress)
Figure 8. Weight of spherical balloons and of cylinder-end balloons with various values of initial meridional stress (zero superpressure, zero circumferential stress).
Figure 9. Weight and gore length of balloons with cylinder-end and taper-tangent end sections and varying initial stress (Zero superpressure, zero circumferential stress, $\Sigma = 0.2$)
2. **Circumferential Stress Equal to Meridional Stress**

Note that it is not possible to have circumferential stress equal to meridional stress at the bottom of the balloon when the payload is applied at a point. Fullness of some kind is required and therefore circumferential stress must be zero. The circumferential stress remains zero until the radius of the balloon exceeds the radius of the end section. At that point in this design, circumferential stress is set equal to meridional stress.

The conditions studied were for zero or low superpressure and for low material stresses. Specifically, in the superpressure range of $0 \leq \alpha \leq 3$ and in the typical polyethylene meridional stress range of $\tau_m = 1$ or $2$, no solutions were found for balloons with a flat top. The sudden change in circumferential stress was the complicating factor. All solutions were either too small—resulting in a peaked top, or too large—resulting in a re-entrant top. There were no intermediate solutions for the conditions studied.

An example of the shape and stress for a balloon with some top loading is shown in Figures 10 and 11. The characteristic inflection in the profile is apparent. The discontinuity in meridional stress is due to the introduction of circumferential stress. Because the meridional stress continues to increase, as opposed to the designs in Figures 4 and 6, the upper cylinder-end section starts immediately above the maximum radius. The weight of this design is $W/P = 0.979$; the load at the bottom is $L/P = 0.685$; the load at the top is $F/P = 0.315$; and the volume is $V/\lambda^3 = 1.979$.

From a practical standpoint it would be better to increase circumferential stress smoothly from its initial zero value. This would permit flat-top solutions at zero superpressure and would probably make it possible to carry the stresses equal to the very top of the balloon.

This design could be an alternate solution to the problem for which the taper-tangent design was evolved.
Figure 10. Shape of a cylinder-end balloon with circumferential stress equal to meridional stress in its fully tailored section and equal to zero in its end sections
($ \xi = 0.176, \alpha = 0.882$)
($L/P = 0.685, F/P = 0.315$)
Figure 11. Meridional stress in a cylinder-end balloon with circumferential stress equal to meridional stress in its fully tailored section and equal to zero in its end sections
($\sum = 0.176, \alpha = 0.882$)
($L/P = 0.685, F/P = 0.315$)
B. Taper-Tangent Balloons

Taper-tangent balloons are much like cylinder-end balloons. Thus, examples with only zero circumferential stress are presented here. Figures 12 and 13 show the effect of varying the initial meridional stress for a constant \( \sigma = 0.2 \). Important differences between these results and the results in Figures 5 and 6 can be noted. In the top of a taper-tangent design, the changeover from the fully tailored section to the end section must occur at a meridional stress value lower than the initial value; otherwise, the final radius will tend to be small and will result in excessive meridional stress. In Figures 12 and 13 the changeover was made arbitrarily when the meridional stress exceeded one-half the initial value. However, when \( \gamma_m \) equaled 0.8 or less, the meridional stress always exceeded one-half the initial value and the changeover occurred at the first point above the maximum radius.

In general, taper-tangent balloons are heavier than cylinder-end balloons. The gore lengths and weights are shown in Figure 9. Note that when \( \gamma_m \) is reduced to about 0.4, the taper-tangent and cylinder-end designs merge into the full-cylinder design.
Figure 12. Shapes of balloons with taper-tangent end sections and varying initial stress (Zero superpressure, zero circumferential stress, $\Sigma = 0.2$)

*(Note: For clarity, the shape for $\tau_{m_0} = 0.6$ is only partially shown.)*
Figure 13. Meridional stress in taper-tangent balloons with varying initial stress
(Zero superpressure, zero circumferential stress, $\Sigma = 0.2$)
C. Tangent-Harness Balloons with Meridional and Circumferential Stress Equal

1. Method of Calculation

Considerable difficulty was experienced in determining the shape of these balloons. Rather than closing smoothly at the top, the balloons had re-entrant or peaked tops. Examination of the first of Equations (1c) shows the reason. By re-writing this equation.

\[ \frac{d\theta}{ds} = \frac{\cos \theta}{r} - \frac{b(z + a) + w \sin \theta}{tm}. \]

Usually, z and w are negligible by comparison and \( tm \) is approximately constant. So

\[ \frac{d\theta}{ds} \approx \frac{\cos \theta}{r} - \text{a constant}. \]

\( \cos \theta \) and \( r \) are small at the top. So as \( r \) decreases, \( (\cos \theta)/r \) will tend to become large--the direction depending on the sign of \( \cos \theta \). Only if all the balloon parameters are chosen correctly will \( (\cos \theta)/r \) behave \( \approx \text{a constant} \). Divergence at the top is the rule rather than the exception.

Trial and error is used to find the proper combinations of parameters. For a particular application, one would usually choose a material weight and desired working stress. By combining these factors with knowledge of the payload, inflation gas, and operating altitude, \( t \) and initial \( t_m \) become fixed. By varying harness radius and \( \lambda \), a solution can be found wherein the balloon will close at the top with the correct curvature and will have the weight and volume in proper proportion. The top curvature should be

\[ \frac{b(z + a)}{2tm} - \frac{w}{tm}, \]

where \( z \) and \( t_m \) are the values at the top. As usual, the weight and volume relationship should be

\[ \frac{V}{\lambda^3} = 1 + \frac{W}{P}. \]
2. Numerical Example

The example chosen is for a balloon at 100,000 ft carrying 300 lb. The material weighs 0.0115 lb/ft$^2$ and the working stress is 174 lb/ft. The lifting gas is helium and the superpressure is 6.34 lb/ft$^2$. The fixed parameters are:

- $\lambda = 68.80$
- $\alpha = 100.0$
- $\sum = 0.3358$
- $\tau_{m_o} = 40.0$

The shape is very nearly spherical. The ratio of minor and major axes is 0.994. Stresses vary as shown in the following table:

<table>
<thead>
<tr>
<th>Location</th>
<th>Stress</th>
</tr>
</thead>
<tbody>
<tr>
<td>At Bottom</td>
<td>40.000</td>
</tr>
<tr>
<td>At Harness:</td>
<td></td>
</tr>
<tr>
<td>Below</td>
<td>40.004</td>
</tr>
<tr>
<td>Above</td>
<td>43.260</td>
</tr>
<tr>
<td>At Equator</td>
<td>43.414</td>
</tr>
<tr>
<td>At Top</td>
<td>43.570</td>
</tr>
</tbody>
</table>

The weight and volume results are:

- $W/P = 1.69$ and $W = 507$ lb
- $V/\lambda^3 = 2.69$ and $V = 876,000$ ft$^3$

For the above conditions, it is interesting to see that the harness radius must be about 0.19 (13.1 ft).

DEFINITION OF SYMBOLS
APPENDIX I
DEFINITION OF SYMBOLS

The symbols used in this series of reports are defined below and illustrated in Figure I-1.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Definition</th>
<th>Dimension</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>pressure head at bottom of balloon</td>
<td>length</td>
</tr>
<tr>
<td>b</td>
<td>difference in weight densities of air and inflation gas</td>
<td>force per unit volume</td>
</tr>
<tr>
<td>k</td>
<td>constant $= (2\pi)^{-1/3}$</td>
<td></td>
</tr>
<tr>
<td>p</td>
<td>gas pressure across the balloon material</td>
<td>force per unit area</td>
</tr>
<tr>
<td>r</td>
<td>radial coordinate of a point on balloon, measured normal to the axis of symmetry</td>
<td>length</td>
</tr>
<tr>
<td>$t_c$</td>
<td>circumferential stress in balloon material</td>
<td>force per unit length</td>
</tr>
<tr>
<td>$t_m$</td>
<td>meridional stress in balloon material</td>
<td>force per unit length</td>
</tr>
<tr>
<td>$t_0, t_1$</td>
<td>constants</td>
<td></td>
</tr>
<tr>
<td>s</td>
<td>gore coordinate of a point on the balloon, measured in the meridional direction from the bottom apex</td>
<td>length</td>
</tr>
<tr>
<td>w</td>
<td>unit weight of balloon material</td>
<td>force per unit area</td>
</tr>
<tr>
<td>z</td>
<td>height coordinate of a point on balloon, measured parallel to the axis of symmetry from the bottom apex</td>
<td>length</td>

<tr>
<td>A</td>
<td>area of balloon surface</td>
<td>length squared</td>
</tr>
<tr>
<td>B</td>
<td>buoyant force on balloon</td>
<td>force</td>
</tr>
<tr>
<td>F</td>
<td>vertical load at top apex of balloon</td>
<td>force</td>
</tr>
</tbody>
</table>
G: gross lift of balloon = b V

L: payload suspended at bottom apex of balloon

P: balloon total payload

\( R_c \): radius of curvature in the circumferential direction = \( r/\cos \theta \)

\( R_m \): radius of curvature in the meridional plane

T: total film load = \( 2\pi \cdot r \cdot t_m \)

V: balloon volume

W: balloon weight

\( \overline{r} \): force

\( \alpha \): \( a/\lambda \)

\( \xi \): \( z/\lambda \)

\( \lambda \): \( (P/b)^{1/3} \)

\( \rho \): \( r/\lambda \)

\( \sigma \): \( s/\lambda \)

\( \tau \): \( t_c/b \lambda^2 \)

\( \tau_m \): \( t_m/b \lambda^2 \)

\( \Sigma \): \( (2\pi)^{1/3} (w/b\lambda) \)

\( \beta \): angle between the balloon material in the end sections and the axis of symmetry--if the end fittings were released and the material fully deployed--measured in a plane containing the axis of symmetry

\( \Theta \): angle between tangent to the balloon surface and axis of symmetry, measured in a plane containing the axis of symmetry

APPENDIX II

SPHERICAL BALLOONS
APPENDIX II

SPHERICAL BALLOONS

A balloon with minimum possible weight would be perfectly spherical. The volume and gore length of a sphere are derived below in terms of the design parameter ($\Sigma$). Symbols are defined in Appendix I.

The gross lift of a balloon is

$$bV = W + P.$$  

The weight and volume of a sphere are

$$W = 4\pi r^2 w,$$

$$V = \left(\frac{4}{3}\right) \pi r^3;$$

so

$$W = 4\pi w \left(\frac{3V}{4\pi}\right)^{2/3}.$$

Thus,

$$bV = \left(36\pi\right)^{1/3} \left(V\right)^{2/3} w + P.$$  

By non-dimensionalizing and noting that

$$P = b\lambda^3,$$

$$k\Sigma = w/b\lambda,$$

$$\Pi-2.$$
we have

\[
\frac{V}{\lambda} = 1 + (18)^{1/3} \sum \left(\frac{V}{\lambda}\right)^{2/3}.
\]

The weight, as usual, is

\[
\frac{W}{\rho} = \frac{V}{\lambda} - 1.
\]

The volume is conveniently solved for by iteration. Let

\[
y^3 = \frac{V}{\lambda};
\]

then Equation (II-1) becomes

\[
y^3 = 1 + (18)^{1/3} \sum y^2.
\]

Also let

\[y_1 = \text{an approximate solution to (II-2)}\]

\[y_2 = \text{a better approximate solution to (II-2)}\]

\[x_1 = \text{the value of } \sum \text{ for which } y_1 \text{ would be a solution}\]

\[\approx (\frac{1}{18})^{1/3} \frac{x_1}{y_1}\]

Then by Newton's method,*

\[
y_2 = y_1 + \frac{\sum x_1 - x_1}{\frac{2}{3} x_1} - \frac{(18)^{1/3} - y_1}{y_1}.
\]

II-3
The gore length of a sphere

\[ s = \pi r. \]

By introducing the sphere weight,

\[ \frac{s^2}{\pi} = \frac{W}{4w}. \]

Then by non-dimensionalizing,

\[ \left( \frac{s}{\lambda} \right)^2 = \frac{1}{2} \left( \frac{\pi^4}{4} \right)^{1/3} \left( \frac{W}{\Sigma} \right) \left( \frac{1}{\lambda} \right). \]

Results for volume, gore length, and other physical characteristics are shown in Table II-1. When \( \Sigma = 0 \), the gore length is determined by our knowledge of \( V/\lambda^3 \). By combining volume and gore length,

\[ V = \frac{4}{3} \frac{s^3}{\pi \lambda^2}; \]

or

\[ \frac{V}{\lambda^3} = \frac{4}{3 \lambda^2} \left( \frac{s}{\lambda} \right)^3. \]

But when \( \Sigma = 0 \),

\[ \frac{V}{\lambda^3} = 1; \]

\[ \frac{V}{\lambda} = 1; \]

* A simple check of Table II-1 will show that the various powers of gore length and volume are not mutually compatible (e.g., for \( \Sigma = 1.0 \), \((2.7527)^3 \neq 20.85847\). However, the data in the table are correct; each number was computed to a accuracy greater than is shown and rounded off to five decimal places.

so

\[
\left( \frac{s}{\lambda} \right)_{\Sigma=0}^3 = \frac{3 \pi^2}{4} = 7.402293301,
\]

and

\[
\left( \frac{s}{\lambda} \right)_{\Sigma=0}^1 = 1.94889
\]

\[
\left( \frac{s}{\lambda} \right)_{\Sigma=0}^2 = 3.79817.
\]

For comparison, the weight of spherical balloons is plotted in Figure 8.
