ABSTRACT

Necessary definitions and theorems from real variable dealing with some properties of Lebesgue-Stieljes measures, monotone non-decreasing functions, Borel sets, functions of bounded variation and Borel measurable functions are set forth in the introduction. Chapter 2 is concerned with establishing a one to one correspondence between Lebesgue-Stieljes measures and certain equivalence classes of functions which are monotone non decreasing and continuous on the right. In Chapter 3 the Lebesgue-Stieljes Integral is defined and some of its properties are demonstrated. In Chapter 4 probability distribution function is defined and the notions in Chapters 2 and 3 are used to show that the Lebesgue-Stieljes integral of any probability distribution function can be expressed as a countable sum of positive numbers added to the Lebesgue-Stieljes integral of a continuous probability distribution function. The conclusion indicates how the Lebesgue-Stieljes integral may be used to define the probability associated with a Borel set of real numbers.

Chapter 1

INTRODUCTION

The terminology and notation used in the thesis is defined below. Certain elementary theorems are stated without proof and proofs are indicated for a few properties of Borel sets, Lebesgue-Stieljes measures, functions of bounded variation and Borel measurable functions. These theorems and properties are used in the subsequent chapters. The proofs are included in the introduction to avoid breaking the continuity of various discussions.

DEFINITION 1.1

\( \mathbb{R} \) is the collection of all real numbers.

DEFINITION 1.2

\( \mathbb{R}^* \) is the collection of all real numbers and \(+\infty\).

DEFINITION 1.3

A set is any collection of real numbers.

DEFINITION 1.4

A class is a collection of anything other than real numbers.

DEFINITION 1.5

An algebra \( \mathcal{A} \) is a non empty class of subsets of \( \mathbb{R} \) such that if \( A \) and \( B \) are in \( \mathcal{A} \) so is \( A \cup B \) and if \( A \) is in \( \mathcal{A} \) so is \( \overline{A} \).

THEOREM 1.1

An algebra \( \mathcal{A} \) is closed for the taking of finite unions and intersections. \( \mathbb{R} \) and \( \emptyset \) are elements of \( \mathcal{A} \).

DEFINITION 1.6

A \( \sigma \)-algebra \( \mathcal{S} \) is an algebra where every union of a countable number of sets in \( \mathcal{S} \) is again in \( \mathcal{S} \).
THEOREM 1.2

A \( \sigma \)-algebra \( \mathcal{A} \) is closed for the taking of countable intersections.

THEOREM 1.3

There exists a minimal \( \sigma \)-algebra which contains the class of all intervals.

Proof: Let \( K \) denote the collection of all \( \sigma \)-algebras that contain the class of all intervals. The class of all subsets of \( \mathbb{R} \) is an element of \( K \) and therefore \( K \) is not empty. Let

\[
\mathcal{B} = \bigcap \{ \mathcal{A} : \mathcal{A} \in K \}
\]

Then \( \mathcal{B} \) is a \( \sigma \)-algebra and if \( \mathcal{A} \) is a \( \sigma \)-algebra in \( K \), \( \mathcal{B} \) is a sub-class of \( \mathcal{A} \). Further \( \mathcal{B} \) contains the class of all intervals and hence \( \mathcal{B} \) is in \( K \). \( \mathcal{B} \) is therefore the minimal \( \sigma \)-algebra containing the class of all intervals.

DEFINITION 1.7

The class \( \mathcal{B} \) is the class of Borel sets.

DEFINITION 1.8

A function on \( A \) to \( B \) mates every element of \( A \), the domain of the function, with a unique element of \( B \). It is not necessary that all elements of \( B \) be used.

DEFINITION 1.9

A set function, \( \phi \), is a function on a given class of sets to \( \mathbb{R}^* \) such that \( \phi \) mates at least one set to an element of \( \mathbb{R} \).

DEFINITION 1.10

A countably additive set function, \( \phi \), is a set function such that for every \( \bigcup_{i=1}^{\infty} A_i \) in the domain of \( \phi \) where the \( A_i \)'s are disjoint sets
in the domain of \( \varphi \)

\[
\varphi\left( \bigcup_{i=1}^{\infty} A_i \right) = \sum_{i=1}^{\infty} \varphi A_i
\]

**DEFINITION 1.11**

A measure is a non-negative, countably additive set function defined on an algebra.

**DEFINITION 1.12**

A Lebesgue-Stieljes measure, \( \mu \), is a measure that mates finite numbers to finite intervals.

**THEOREM 1.4**

Let \( \mu \) be a Lebesgue-Stieljes measure. If \( B_1 \subseteq B_2 \) and both \( B_1 \) and \( B_2 \) are in the domain of \( \mu \), then

\[ \mu B_1 \leq \mu B_2. \]

Proof: Since \( B_2 - B_1 = B_2 \cap B_1 \), \( B_2 - B_1 \) is in the domain of \( \mu \).

\[
\mu B_2 = \mu \left[ (B_2 - B_1) \cup B_1 \right] \\
= \mu (B_2 - B_1) + \mu B_1 \\
\geq \mu B_1
\]

**THEOREM 1.5**

If \( \mu \) is a Lebesgue-Stieljes measure, then

\[ \mu \varnothing = 0 \]

Proof:

\[
\mu A = \mu (A + \varnothing) \\
= \mu A + \mu \varnothing.
\]

**DEFINITION 1.13**

\( \mathcal{M} \) is the class of all monotone non-decreasing functions defined on \( \mathbb{R} \) and continuous on the right.
DEFINITION 1.14

$F_1$ and $F_2$ are $r$-related if $F_1$ and $F_2$ are functions in $\mathcal{M}$ that
differ by a constant.

THEOREM 1.6

The $r$-relation divides $\mathcal{M}$ into equivalence classes.

Proof: The $r$-relation is evidently symmetric, reflexive and transitive.

THEOREM 1.7

Every function in $\mathcal{M}$ is in one and only one equivalence class.

DEFINITION 1.15

$E$ is the collection of all equivalence classes in $\mathcal{M}$.

DEFINITION 1.16

Let $F$ be a function defined on $\mathbb{R}$ and let $b$ be an element of $\mathbb{R}^*$.
Suppose $F$ is such that $\lim_{x \to -\infty} F(x)$ exists and, in case $b = +\infty$,

$$\lim_{x \to -\infty} F(x)$$

exists. Define $F(-\infty) = \lim_{x \to -\infty} F(x)$ and in case $b = +\infty$

define $F(b) = \lim_{x \to +\infty} F(x)$. If there exists a "finite partition",

$$-\infty = x_0 < x_1 < \cdots < x_n = b$$

define $F(b) = \lim_{x \to +\infty} F(x)$. If there exists a "finite partition",

$$-\infty = x_0 < x_1 < \cdots < x_n = b$$

for some real number $k$, then $F$ is a function of bounded variation on

$(-\infty, b]$. In case $b = +\infty$, $F$ will be said to be of bounded varia-
tion on $\mathbb{R}$ (or simply a function of bounded variation.)

THEOREM 1.8

If $F$ is of bounded variation on $(-\infty, b]$, then $F$ equals the dif-
ference of two monotone non-decreasing functions on $(-\infty, b]$. The proof
of the following:
LEMMA 1.8.1

For every finite partition of \((-\infty, b]\),
\[ F(b) - F(-\infty) = \sum_{i=1}^{\infty} [F(x_i) - F(x_{i-1})] \]

DEFINITION 1.16.1

The total variation of \(F\) on \((-\infty, b]\), \(V_{-\infty}^b\), is
\[ \sup \sum_{i=1}^{\infty} |F(x_i) - F(x_{i-1})|. \]

Evidently \(V_{-\infty}^b \leq \kappa\).

LEMMA 1.8.2

For every finite partition of \((-\infty, b]\)
\[ F(b) - F(-\infty) = \Sigma_+ + \Sigma_- \]

where \(\Sigma_+\) is the sum of all the positive terms in \(\sum_{i=1}^{\infty} [F(x_i) - F(x_{i-1})]\)
and \(\Sigma_-\) is the sum of the other terms.

DEFINITION 1.16.2

The positive variation of \(F\), \(P_{-\infty}^b\), is the supremum of \(\Sigma_+\) over all finite partitions of \((-\infty, b]\). The negative variation of \(F\), \(N_{-\infty}^b\), is the supremum of \(-\Sigma_-\) for all finite partitions of \((-\infty, b]\).

LEMMA 1.8.3

\[ P_{-\infty}^b = \frac{1}{2} \left[ V_{-\infty}^b + F(b) - F(-\infty) \right] \]
\[ N_{-\infty}^b = \frac{1}{2} \left[ V_{-\infty}^b + F(-\infty) - F(b) \right] \]
Proof: Since

$$\sum_{\xi = i}^{\infty} \left[ F(x_{\xi}) - F(x_{\xi-1}) \right] = \Sigma_+ + \Sigma_- = F(b) - F(-\infty)$$

and

$$\sum_{\xi = i}^{\infty} \left| F(x_{\xi}) - F(x_{\xi-1}) \right| = \Sigma_+ - \Sigma_- \leq V_{-\infty}^b$$

it follows that

$$\Sigma_+ \leq \frac{1}{2} \left[ V_{-\infty}^b + F(b) - F(-\infty) \right]$$

and

$$-\Sigma_- \leq \frac{1}{2} \left[ V_{-\infty}^b + F(-\infty) - F(b) \right].$$

On the other hand for every $\xi > 0$ there exists a finite partition of $(-\infty, b]$ such that

$$\sum_{\xi = i}^{n} \left| F(x_{\xi}) - F(x_{\xi-1}) \right| > V_{-\infty}^b - \epsilon.$$

Hence for this partition a similar argument shows that

$$\Sigma_+ > \frac{1}{2} \left[ V_{-\infty}^b - \epsilon + F(b) - F(-\infty) \right]$$

and

$$-\Sigma_- > \frac{1}{2} \left[ V_{-\infty}^b - \epsilon - F(b) + F(-\infty) \right].$$

Thus the lemma holds.

**Lemma 1.8.4**

$$V_{-\infty}^b = P_{-\infty}^b + N_{-\infty}^b$$

$$F(b) = F(+\infty) = P_{-\infty}^b - N_{-\infty}^b$$

Proof: These equations follow from adding and subtracting the equations of the preceding lemma.
LEMMA 1.8.5
For all \( x \),
\[
F(x) = P_{-\infty}^x - [ N_{-\infty}^x - F(-\infty) ].
\]

LEMMA 1.8.6
If \( x < x' \), then
\[
N_{-\infty}^x \leq N_{-\infty}^{x'} \quad \text{and} \quad P_{-\infty}^x \leq P_{-\infty}^{x'}
\]

Proof: Obviously \( \Sigma_+ \) cannot be greater for \( (-\infty, x] \) than for \( (-\infty, x'] \). Similarly \( \Sigma_- \) cannot be greater for \( (-\infty, x] \) than for \( (-\infty, x'] \). The theorem follows from lemma 1.8.5 and lemma 1.8.6.

DEFINITION 1.17
A function \( g \) is Borel measurable if \( \{ x: g(x) \geq k \} \) is a Borel set for every \( k \).

THEOREM 1.9
If \( g \) is Borel measurable, then \( \{ x: g(x) < k \}, \{ x: g(x) \leq k \} \) and \( \{ x: g(x) > k \} \) are Borel sets for every \( k \).

Proof: Since
\[
\{ x: g(x) \geq k \} = \{ x: g(x) < k \}
\]
for every \( k \) and the Borel sets are closed for the taking of complements, \( \{ x: g(x) < k \} \) is a Borel set for every \( k \). Since
\[
\bigcap_{i=1}^{\infty} \{ x: g(x) < k + \frac{1}{i} \} = \{ x: g(x) \leq k \}
\]
for every \( k \) and the Borel sets are closed for the taking of countable intersections, \( \{ x: g(x) \leq k \} \) is a Borel set. Finally \( \{ x: g(x) > k \} \)
is a Borel set for all $k$ because

$$\{ x : g(x) \leq k \} = \{ x : g(x) > k \}.$$  

**Theorem 1.10**

If $g$ is a Borel measurable function, $Kg$ is a Borel measurable function for every fixed real number $K$.

**Proof:** When $K = 0$, the theorem is obvious. When $K > 0$

$$\{ x : Kg(x) \geq k \} = \{ x : g(x) \geq \frac{k}{K} \}.$$  

When $K < 0$

$$\{ x : Kg(x) \geq k \} = \{ x : g(x) \leq \frac{k}{K} \}.$$  

**Theorem 1.11**

If $g_1$ and $g_2$ are Borel measurable, then $g_1 + g_2$ is Borel measurable.

**Proof:** If $g_1(x) + g_2(x) < k$, there exists a rational number $r$ such that

$$g_1(x) < r < k - g_2(x).$$

Hence writing the rationals in a sequence $r_1, r_2, \ldots$,

$$\{ x : g_1(x) + g_2(x) < k \} \subset \bigcup_{i=1}^{\infty} \left[ \{ x : g_1(x) < r_i \} \cap \{ x : g_2(x) < k - r_i \} \right].$$

On the other hand, if there exists a rational number $r_n$ such that $g_1(x) < r_n$ and $g_2(x) < k - r_n$, then $g_1(x) + g_2(x) < k$. It follows that

$$\{ x : g_1(x) + g_2(x) < k \} \supset \bigcup_{i=1}^{\infty} \left[ \{ x : g_1(x) < r_i \} \cap \{ x : g_2(x) < k - r_i \} \right].$$

Hence

$$\{ x : g_1(x) + g_2(x) < k \} = \bigcup_{i=1}^{\infty} \left[ \{ x : g_1(x) < r_i \} \cap \{ x : g_2(x) < k - r_i \} \right].$$
Taking complements

\[ \{ x : q_i(x) + q_k(x) \geq k \} = \bigcap_{i=1}^{\infty} \left[ \{ x : q_i(x) \geq r_k \} \cup \{ x : q_k(x) \geq k - r_k \} \right] \]

**Theorem 1.12**

If for every \( n \), \( g_n \) is Borel measurable and if

\[ \lim_{n \to \infty} g_n(x) = g(x) \]

then \( g \) is also Borel measurable.

**Proof:** Take an \( x \) in \( \{ x : g(x) < k \} \) and choose \( m \) large enough that

\[ \frac{1}{m} < \frac{1}{2} \left[ k - q(x) \right] \].

Because of convergence there exists an \( N \) such that for every \( n > N \)

\[ q_n(x) < q(x) + \frac{1}{m} < k - \frac{1}{m} \]

Hence \( x \) is in \( \bigcap_{m=1}^{\infty} \bigcap_{n=1}^{\infty} \{ x : q_n(x) < k - \frac{1}{m} \} \).

On the other hand take \( x \) in \( \bigcap_{m=1}^{\infty} \bigcap_{n=1}^{\infty} \{ x : q_n(x) < k - \frac{1}{m} \} \).

Then for some \( m \) there exists an \( N \) such that for every \( n > N \),

\[ q_n(x) < k - \frac{1}{m} \].

Because of convergence

\[ q(x) \leq k - \frac{1}{m} < k \]

Hence \( x \) is in \( \{ x : q(x) < k \} \).
Then

$$\{ x : g(x) < k \} = \bigcup_{m \geq 1} \bigcup_{N \geq 1} \cap_{n \geq N+1} \{ x : g_n(x) < k - \frac{1}{m} \}.$$ 

Taking complements and observing that the Borel measurability of the $g_n$'s implies the set on the right is a Borel set, it follows that $\{ x : g(x) \geq k \}$ is a Borel set and hence $g(x)$ is Borel measurable.
Chapter 2

FUNCTIONS OF $\mathcal{M}$ AND LEBESGUE-STIELJES MEASURES

It will be shown that there exists a biunique correspondence between the equivalence classes in $E$ and all Lebesgue-Stieljes measures on $\mathbb{B}$.

**THEOREM 2.1:**

For every $M$ in $E$ there exists a unique Lebesgue-Stieljes measure, $\mu$, such that for each $F$ in $M$ and for every $a < b$

$$\mu(a,b] = F(b) - F(a)$$

The proof of theorem 2.1 proceeds as follows:

**DEFINITION 2.1.1**

$$C_1 = \{\emptyset, (a,b], (-\infty,b], (a,\infty), \mathbb{R} \text{ for every } a < b \}$$

**LEMMA 2.1.1**

$C_1$ is closed for the taking of finite intersections.

**LEMMA 2.1.2**

The complement of any set in $C_1$ is in $C_1$ or is the union of two disjoint sets in $C_1$.

**LEMMA 2.1.3**

The union of any two overlapping or abutting sets in $C_1$ is in $C_1$.

**DEFINITION 2.1.2**

$$\mu \emptyset = 0$$

$$\mu(a,b] = F(b) - F(a)$$

$$\mu(-\infty,b] = \lim_{x \to -\infty} \mu(x,b]$$

$$\mu(a,\infty) = \lim_{x \to \infty} \mu(a,x]$$

$$\mu \mathbb{R} = \lim_{x \to \infty} \lim_{y \to -\infty} \mu(x,y]$$
LEMMA 2.1.4

Every $F$ in a given $M$ determines the same $\mu$.

DEFINITION 2.1.3

$$C_2 = \{A; \text{either } A \text{ is in } C_1 \text{ or } A = \bigcup_{i=1}^{n} A_i \text{ where the } A_i \text{'s are disjoint sets in } C_1\}$$

LEMMA 2.1.5

$$C_1 \subset C_2$$

LEMMA 2.1.6

$C_2$ is closed for the taking of finite unions.

Proof: First consider that if $A$ is in $C_1$ and $\bigcup_{i=1}^{n} B_i$ is such that every $B_i$ is in $C_1$, $\bigcup_{i=1}^{n} B_i \cup A$ is in $C_2$. This follows from the distributive law for unions, Lemma 2.1.3 and the definition of $C_2$. Again considering the distributive law for unions, the union of any two sets in $C_2$ is in $C_2$. The lemma follows by induction.

LEMMA 2.1.7

$C_2$ is closed for the taking of finite intersections.

Proof: The lemma follows from the distributive law for intersections, Lemma 2.1.1, the definition of $C_2$, and induction.

LEMMA 2.1.8

$C_2$ is closed for the taking of complements.

Proof: If $A$ is in $C_2$ and every $A_i$ is in $C_1$, $\overline{A} = \bigcup_{i=1}^{n} A_i$, $\overline{A} = \bigcap_{i=1}^{n} A_i$.
It follows from lemma 2.1.2 that every $A_i$ is in $C_2$. The lemma follows from lemma 2.1.7.

**LEMMA 2.1.8**

$C_2$ is an algebra of sets.

**DEFINITION 2.1.4**

For every $A$ in $C_2$ let

$$
\mu A = \bigcup_{i=1}^{\infty} \mu A_i
$$

where $\bigcup_{i=1}^{\infty} A_i = A$ and the $A_i$'s are disjoint sets in $C_1$.

**LEMMA 2.1.9**

$\mu$ is uniquely defined on $C_2$.

Proof: If $S = \bigcup_{i=1}^{\infty} S_i$ where the $S_i$'s are in $C_2$, then $S = \bigcup_{i=1}^{\infty} A_i$ where

$$
A_i = S_i \cap \left[ \bigcup_{j=1}^{\infty} S_j \right]
$$

which implies the $A_i$'s are disjoint and in $C_2$.

If $\bigcup_{i=1}^{\infty} A_i = \bigcup_{j=1}^{\infty} B_j$, the $A_i$'s are disjoint sets in $C_1$ and so are $B_j$'s.

It follows that

$$
A_i = \bigcup_{j=1}^{\infty} B_j \cap A_i \quad \text{and} \quad B_j = \bigcup_{i=1}^{\infty} A_i \cap B_j.
$$

Hence

$$
\mu A_i = \sum_{j=1}^{\infty} \mu (B_j \cap A_i) \quad \text{and} \quad \mu B_j = \sum_{i=1}^{\infty} \mu (A_i \cap B_j)
$$

It follows that

$$
\sum_{i=1}^{\infty} A_i = \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \mu (A_i \cap B_j) = \sum_{j=1}^{\infty} \mu B_j.
$$

**LEMMA 2.1.10**

If $A$ and $B$ are in $C_2$ and $A \subseteq B$,

$$
\mu A \leq \mu B.
$$
Proof: Since \( B - A = B \cap \overline{A} \) is in \( C_2 \),

\[
\mu B = \mu [(B-A) \cup A] = \mu (B-A) + \mu A
\]

**Lemma 2.1.11**

\( \mu \) is countably additive on \( C_2 \).

Proof: It is sufficient to show that if \( \bigcup_{i=1}^{\infty} A_i \) is in \( C_2 \) and the \( A_i \)'s are disjoint sets in \( C_1 \), then

\[
\mu \left( \bigcup_{i=1}^{\infty} A_i \right) = \sum_{i=1}^{\infty} \mu A_i
\]

Consider first that if \((a,b] = \bigcup_{i=1}^{\infty} [a_i,b_i] \) where all the intervals are disjoint, then \( \bigcup_{i=1}^{n} (a_i,b_i] \) is a subset of \((a,b] \). Hence for all \( n \),

\[
\mu (a,b] \geq \sum_{i=1}^{n} \mu (a_i,b_i]
\]

It follows that

\[
\mu (a,b] \geq \sum_{i=1}^{\infty} \mu (a_i,b_i].
\]

The same inequality follows in a similar fashion for \( \mu (a,\infty) \), \( \mu (-\infty,b] \) and \( \mu R \).

To show the reverse inequality, first consider \( a \) and \( b \) finite. Since \( F \) is continuous on the right, for every \( \epsilon > 0 \) there exists a \( \delta > 0 \) such that

\[
F(a+b^\prime) < F(a) + \epsilon
\]

Moreover for every \( i \), there exists an \( \eta_i > 0 \) such that

\[
F(b^\prime + \eta_i) < F(b^\prime) + \epsilon 2^{-i}.
\]

Further

\[
[a+\delta,b] \subset (a,b] = \bigcup_{i=1}^{\infty} (a_i,b_i] \subset \bigcup_{i=1}^{\infty} (a_i,b_i+\eta_i)
\]
Hence by the Heine Borel theorem there exists an integer \( m \) such that

\[
[a + \delta, b] \subset \bigcup_{i=1}^{m} (a_i, b_i + \eta_i).
\]

Consequently, renaming the end points of the intervals if necessary, \( a + \delta \) is in \((s_1, b_1 + \eta_1)\) and for some integer \( k \) between 1 and \( n \) inclusive \( b \) is in \((a_k, b_k + \eta_k)\).

Suppose the least \( k \) is one. Then since \([a + \delta, b]\) is a subset of \((a_1, b_1 + \eta_1)\), it follows that

\[
F(a) \leq F(a + \delta) < F(a) + \epsilon
\]

and

\[
F(b) \leq F(b + \eta_1) < F(b) + \epsilon 2^{-1}.
\]

Hence

\[
F(b) - F(a) - \epsilon < F(b) - F(a) + \epsilon 2^{-1}.
\]

It follows that \( \mu(a, b] \leq \mu(a_1, b_1] \) which implies that

\[
\mu(a, b] \leq \sum_{k=1}^{\infty} \mu(a_k, b_k].
\]

Suppose the least \( k \) is greater than one. Then \( b \geq b_1 + \eta_1 \), which implies that \( b_1 + \eta_1 \) is in \((a, b]\). Since \( b_1 + \eta_1 \) is not in \((a_1, b_1 + \eta_1)\) there must exist an integer \( j \) greater than one such that \( b_1 + \eta_1 \) is in \((a_j, b_j + \eta_j)\). If \( j \) is not two, let the jth interval be second and the second, the jth. Then

\[
a_2 < b_1 + \eta_1 < b_2 + \eta_2.
\]

This procedure may be repeated if necessary until the first \((a_k, b_k + \eta_k)\) where \( b < b_k + \eta_k \). Then

\[
[a + \delta, b] \subset \bigcup_{i=1}^{k} (a_i, b_i + \eta_i).
\]
and for every integer \( j \) such that \( 1 < j \leq k \)

\[ a_j < b_{j-1} + \eta_{j-1} < b_j + \eta_j. \]

Since \( F \) is non-decreasing, it follows that

\[
\sum_{i=1}^{k} \left[ F(b_{i} + \eta_{i}) - F(a_{i}) \right] = F(b_k + \eta_k) - F(a_k) \\
+ \sum_{i=1}^{k-1} \left[ F(b_{i} + \eta_{i}) - F(a_{i+1}) \right] \\
\geq F(b_k + \eta_k) - F(a_1) \\
> F(b) - F(a + \delta) \\
> F(b) - F(a) - \epsilon.
\]

However

\[
\sum_{i=1}^{k} F(b_{i} + \eta_{i}) < \sum_{i=1}^{k} F(b_{i}) + \epsilon \sum_{i=1}^{k} 2^{-i}
\]

It follows that

\[
\sum_{i=1}^{k} \left[ F(b_{i}) - F(a_{i}) \right] \geq F(b) - F(a) - \epsilon \left[ 1 + \sum_{i=1}^{k} 2^{-i} \right]
\]

Since this inequality holds for any integer greater than \( k \),

\[
\sum_{i=1}^{\infty} \mu(a_i, b_i] \geq \mu(a, b].
\]

Therefore for \( a \) and \( b \) finite,

\[
\mu(a, b] = \sum_{i=1}^{\infty} \mu(a_i, b_i].
\]

Assume now that \((a, \infty)\) equals \( \bigcup_{i=1}^{\infty} (a_i, b_i] \) where

\[ \epsilon = a_1 < b_1 = a_2 < \ldots \]

where \( \lim_{n \to \infty} b_n = \infty \). For every finite value of \( x \)
greater than a, \((a,x \in C) (a_i^\prime, b_i)\). It follows that there must be a
\(b_n \in x\).

Hence

\[
\mu(a,x) \leq F(b_n) - F(a_i) \\
= \sum_{i=1}^{\infty} [F(b_i) - F(a_i)] \\
\leq \sum_{i=1}^{\infty} [F(b_i) - \\
= \sum_{i=1}^{\infty} \mu(a_i, b_i). \\
\]

Similarly it may be shown that if \((-\infty, b]\) equals \(\bigcup_{i=1}^{\infty} (a_i, b_i]\)

\[
\mu(-\infty, b] \leq \sum_{i=1}^{\infty} \mu(a_i, b_i] \\
\]
and if \(R\) equals \(\bigcup_{i=1}^{\infty} (a_i, b_i]\)

\[
\mu R \leq \sum_{i=1}^{\infty} \mu(a_i, b_i]. \\
\]

Finally every set in \(C_2\) may be expressed as \(\bigcup_{i=1}^{\infty} A_i\) where the \(A_i\)'s
are disjoint sets in \(C_1\). If \(\bigcup_{i=1}^{\infty} A_i\) equals \(\bigcup_{i=1}^{\infty} (a_i, b_i]\), it follows
that

\[
\bigcup_{i=1}^{\infty} A_i \cap (a_i, b_i] = (a_i, b_i] \quad \text{and} \quad \bigcup_{i=1}^{\infty} (a_i, b_i] \cap A_j = A_j. \\
\]

As a consequence

\[
\mu(a_i, b_i] = \sum_{j=1}^{\infty} \mu[A_j \cap (a_i, b_i)]. \\
\]
\[ \mu A_j = \sum_{i=1}^{\infty} \mu [(a_i, b_i) \cap A_j] \]

Hence

\[ \sum_{j=1}^{n} \mu A_j = \sum_{j=1}^{n} \sum_{i=1}^{\infty} \mu [(a_i, b_i) \cap A_j] \geq \sum_{j=1}^{m} \sum_{i=1}^{\infty} \mu [(a_i, b_i) \cap A_j] = \sum_{i=1}^{\infty} \mu (a_i, b_i) \cdot \]

Letting \( m \) go to infinity gives

\[ \sum_{j=1}^{\infty} \mu A_j = \mu \left[ \bigcup_{i=1}^{\infty} A_i \right] = \sum_{i=1}^{\infty} \mu (a_i, b_i) \]

Hence

\[ \mu \left[ \bigcup_{i=1}^{\infty} (a_i, b_i) \right] = \sum_{i=1}^{\infty} \mu (a_i, b_i) \cdot \]

**LEMMA 2.1.12**

\( \mu \) is a measure on \( C_2 \).

**DEFINITION 2.1.5**

For any subset, \( S \), of \( R \) let

\[ \mu^t S = \inf \sum_{i=1}^{\infty} \mu A_i \cdot \]

where every \( A_i \) is in \( C_2 \), the \( A_i \)'s cover \( S \) and the infimum is with respect to all countable sequences of sets in \( C_2 \) which cover \( S \).
LEMMA 2.1.13
\[ \mu^* \text{ is defined for all subsets of } R. \]

LEMMA 2.1.14
If \( A \) is in \( C_2 \),
\[ \mu^* A = \mu A. \]
Proof: Take any countable sequence of sets from \( C_2 \) which covers \( A \). Denote the members of the sequence by \( B_1, B_2, \ldots \). Then define
\[ A_n = A \cap \bigcup_{i=1}^{n-1} B_i. \]
Then \( A_n \) is in \( C_2 \), the \( A_n's \) are disjoint and \( \bigcup_{i=1}^{\infty} A_i = A \). It follows from lemma 2.1.11 that
\[ \mu A = \sum_{i=1}^{\infty} \mu A_i. \]
Since for all \( n \), \( A_n \) is a subset of \( B_n \) from lemma 2.1.10,
\[ \sum_{i=1}^{\infty} \mu A_i \leq \sum_{i=1}^{\infty} \mu B_i. \]
Hence
\[ \mu A \leq \sum_{i=1}^{\infty} \mu B_i. \]
To complete the proof consider the sequence \( A, \emptyset, \emptyset, \ldots \).
\[ \mu^* A \leq \mu A + \mu \emptyset + \mu \emptyset + \ldots. \]
If \( \mu^* A \) is less than \( \mu A \), there will exist a sequence of sets \( B_1, B_2, \ldots \) from \( C_2 \) which covers \( A \) and is such that
\[ \mu^* A + \epsilon > \sum_{i=1}^{\infty} \mu B_i. \]
where \( \epsilon = \mu A - \mu^* A > 0 \). This implies that

\[
\mu A > \sum_{i=1}^{\infty} \mu B_i
\]

which is impossible. Hence

\[
\mu A \cdot \mu^* A
\]

**Lemma 2.1.15**

\[
\mu^* \emptyset = 0
\]

**Lemma 2.1.16**

If \( S_1 \) is a subset of \( S_2 \), \( \mu^* S_1 \leq \mu^* S_2 \).

**Lemma 2.1.17**

If \( S \) is covered by a sequence of sets, \( S_1, S_2, \ldots \),

\[
\mu^* S \leq \sum_{i=1}^{\infty} \mu^* S_i.
\]

Proof: The statement is trivial when \( \mu^* S \) is infinite. When \( \mu^* S \) is finite for every \( S_i \) and every \( \epsilon > 0 \) there exists a sequence of sets from \( C_2 = A_{11}, A_{12}, \ldots \), which cover \( S_1 \) and are such that

\[
\sum_{i=1}^{\infty} \mu A_{i,j} < \mu^* S_i + \epsilon 2^i.
\]

Hence

\[
\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \mu A_{i,j} < \sum_{i=1}^{\infty} \mu^* S_i + \epsilon.
\]

Since \( S \) is covered by \( S_1, S_2, \ldots \) and \( S_i \) is covered by \( A_{11}, A_{12}, \ldots \) it follows that \( S \) is covered by \( A_{11}, A_{12}, \ldots \). Hence

\[
\mu^* S \leq \mu^* (\bigcup_{i=1}^{\infty} \bigcup_{j=1}^{\infty} A_{i,j}).
\]
\[ \mu \leq \sum_{i=1}^{n} \sum_{j=1}^{m} \mu A_{ij} \]
\[ < \sum_{i=1}^{n} \mu^* S_i + \varepsilon \]
Consequently
\[ \mu^* S \leq \sum_{i=1}^{n} \mu^* S_i. \]

**DEFINITION 2.1.6**

The class of all \( \mu \)-measurable sets of real numbers, \( C_3 \), is the class of all sets of real numbers \( A \) such that
\[ \mu^* S \geq \mu^* (S \cap A) + \mu^* (S - A) \]
where \( S \) is an arbitrary set of real numbers. \( S \) is called a test set.

**LEMMA 2.1.18**

\( \emptyset \) is in \( C_3 \).

**LEMMA 2.1.19**

If \( A \) is in \( C_3 \), \( \bar{A} \) is in \( C_3 \).

**LEMMA 2.1.20**

If \( A_1, A_2, \ldots, A_n \) is a finite sequence of sets in \( C_3 \), \( \bigcup_{i=1}^{n} A_i \) is in \( C_3 \).

**Proof:** Using induction, suppose \( A_1 \) and \( A_2 \) are in \( C_3 \). Then for every set \( S \),
\[ \mu^* S \geq \mu^* (S \cap A_1) + \mu^* (S - A_1). \]

Using \( S - A_1 \) as a test set,
\[ \mu^* (S - A_1) \geq \mu^* (S - A_1 \cap A_2) + \mu^* (S - A_1 - A_2) \]

Hence
\[ \mu^* S \geq \mu^* (S \cap A_1) + \mu^* (S - A_1 \cap A_2) + \mu^* (S - A_1 - A_2). \]
\[ \sum \mu^* [(S \cap A_1) U (S-A_1 \cap A_2)] + \mu^* [S-(A_1 U A_2)] \]

= \[ \mu^* [S \cap (A_1 U A_2)] + \mu^* [S-(A_1 U A_2)] \]

The lemma follows by induction.

**LEMMA 2.1.21**

If \( A_1, A_2, \ldots, A_n \) is a finite sequence of disjoint sets in \( C_3 \) and \( S \) is any set of real numbers,

\[ \mu^*(S \cap \bigcup_{i=1}^{n} A_i) = \sum_{i=1}^{n} \mu^*(S \cap A_i). \]

Proof: Using induction again, the statement is trivial when \( n = 1 \). Making the induction hypothesis, using lemma 2.1.20 to assert that

\[ \bigcup_{i=1}^{n} A_i \] is in \( C_3 \) and using \( S \cap \bigcup_{i=1}^{n} A_i \) as a test set,

\[ \mu^*(S \cap \bigcup_{i=1}^{n} A_i) \geq \mu^*(S \cap \bigcup_{i=1}^{n} A_i \cap \bigcap_{i=1}^{n} A_i) + \mu^*(S \cap \bigcup_{i=1}^{n} A_i - \bigcup_{i=1}^{n} A_i) \]

\[ \geq \mu^*(S \cap \bigcup_{i=1}^{n} A_i) + \mu^*(S \cap A_{n+1}) \]

By the induction hypothesis

\[ \mu^*(S \cap \bigcup_{i=1}^{n} A_i) = \sum_{i=1}^{n} \mu^*(S \cap A_i). \]

It follows from lemma 2.1.17 that

\[ \mu^*(S \cap \bigcup_{i=1}^{n} A_i) \leq \sum_{i=1}^{n+1} \mu^*(S \cap A_i). \]

Therefore

\[ \mu^*(S \cap \bigcup_{i=1}^{n+1} A_i) = \sum_{i=1}^{n+1} \mu^*(S \cap A_i). \]
LEMMA 2.1.22

If \( A_1, A_2, \ldots \) is a denumerable sequence of disjoint sets in \( C_3 \) and if \( S \) is an arbitrary set of real numbers,

\[
\mu^* (S \cap \bigcup_{i=1}^{\infty} A_i) = \sum_{i=1}^{\infty} \mu^* (S \cap A_i)
\]

Proof: Since, for every \( n \), \( \bigcup_{i=1}^{n} A_i \) is a subset of \( \bigcup_{i=1}^{\infty} A_i \), it follows that

\[
\mu^* (\bigcup_{i=1}^{n} A_i \cap S) \geq \mu^* (\bigcup_{i=1}^{\infty} A_i \cap S) = \sum_{i=1}^{n} \mu^* (A_i \cap S)
\]

Letting \( n \) go to infinity, it follows that

\[
\mu^* (\bigcup_{i=1}^{\infty} A_i \cap S) \geq \sum_{i=1}^{\infty} \mu^* (A_i \cap S)
\]

Since \( A_1 \cap S, A_2 \cap S, \ldots \) cover \( \bigcup_{i=1}^{\infty} (A_i \cap S) \), it follows from lemma 2.1.17 that

\[
\mu^* (\bigcup_{i=1}^{\infty} A_i \cap S) \leq \sum_{i=1}^{\infty} \mu^* (A_i \cap S)
\]

Thus

\[
\mu^* (\bigcup_{i=1}^{\infty} A_i \cap S) = \sum_{i=1}^{\infty} \mu^* (A_i \cap S)
\]

LEMMA 2.1.23

If \( A_1, A_2, \ldots \) is a denumerable sequence of sets in \( C_3 \), \( \bigcap_{i=1}^{\infty} A_i \) in \( C_3 \).

Proof: Taking only \( A_1, A_2, \ldots , i \), it follows from lemma 2.1.20 that for an arbitrary set \( S \),

\[
\mu^* S \geq \mu^* (S \cap \bigcup_{i=1}^{n} A_i) + \mu^* (S - \bigcup_{i=1}^{n} A_i).
\]
Moreover from lemma 2.1.20

\[ \mu^* \left( \bigcap_{i=1}^{n} A_i \right) = \sum_{i=1}^{n} \mu^* \left( S \cap A_i \right) \]

and from lemma 2.1.16 and the fact that \( \bigcup_{i=1}^{n} A_i \supset \bigcup_{i=1}^{n} A_i \),

\[ \mu^* \left( S - \bigcup_{i=1}^{n} A_i \right) \supset \mu^* \left( S - \bigcup_{i=1}^{n} A_i \right) \]

Thus

\[ \mu^* S \geq \sum_{i=1}^{n} \mu^* \left( A_i \cap S \right) + \mu^* \left( S - \bigcup_{i=1}^{n} A_i \right) \]

Letting \( n \) go to infinity

\[ \mu^* S \geq \sum_{i=1}^{\infty} \mu^* \left( A_i \cap S \right) + \mu^* \left( S - \bigcup_{i=1}^{\infty} A_i \right) \]

It follows from lemma 2.1.22 that

\[ \mu^* S \geq \mu^* \left( \bigcap_{i=1}^{\infty} A_i \right) + \mu^* \left( S - \bigcup_{i=1}^{\infty} A_i \right) \]

It follows that \( \bigcup_{i=1}^{\infty} A_i \) is in \( C_3 \).

**Lemma 2.1.24**

\( C_2 \) is a subset of \( C_3 \).

**Proof:** If \( A \) and \( B \) are two arbitrary sets in \( C_2 \), \( A \cap B \) and \( A - B \) are disjoint and in \( C_2 \). The union of \( A \cap B \) and \( A - B \) is \( A \).

Hence

\[ \mu^* \left( A \cap B \right) + \mu^* \left( A - B \right) = \mu^* A. \]

For \( S \), an arbitrary set of real numbers, if \( \mu^* S \) is infinite

\[ \mu^* S = \mu^* \left( S \cap A \right) + \mu^* \left( S - A \right) \]

for all \( A \) in \( C_2 \).
If $\mu^*S$ is finite, then from the definition it follows that for every $\varepsilon > 0$, there exists a sequence, $A_1, A_2, \cdots$ in $C_2$ which covers $S$ and is such that

$$\mu^*S + \varepsilon > \sum_{\ell = 1}^{\infty} \mu(A_{\ell}) = \sum_{\ell = 1}^{\infty} \left[ \mu(A_{\ell} \cap A) + \mu(A_{\ell} - A) \right]$$

for some $A$ in $C_2$. However, $S \cap A$ is a subset of $\bigcup_{\ell = 1}^{\infty} (A_{\ell} \cap A)$ and $A_1 \cap A, A_2 \cap A, \cdots$ is a sequence of sets in $C_2$. Similarly $S - A$ is a subset of $\bigcup_{\ell = 1}^{\infty} (A_{\ell} - A)$ and $A_1 - A, A_2 - A, \cdots$ is a sequence of sets in $C_2$. It follows that

$$\mu^*(S \cap A) + \mu^*(S - A) \leq \sum_{\ell = 1}^{\infty} \left[ \mu(A_{\ell} \cap A) + \mu(A_{\ell} - A) \right].$$

Hence

$$\mu^*S \geq \mu^*(S \cap A) + \mu^*(S - A)$$

It follows that $A$ is in $C_3$.

**Lemma 2.1.25**

$C_3$ is a $\sigma$-algebra which contains $C_2$.

**Lemma 2.1.26**

$B$ is a subset of $C_3$.

Restricting the domain of $\mu^*$ to $B$ it follows that:

**Lemma 2.1.27**

$\mu^*$ is countably additive.

Proof: Induction may be used to show

$$\mu^*\left(\bigcup_{\ell = 1}^{\infty} A_{\ell}\right) = \sum_{\ell = 1}^{\infty} \mu^*A_{\ell}$$
The statement is trivial for \( n = 1 \). Making the induction hypothesis, recalling that \( \bigcup_{k=1}^{n} A_k \) is in \( C_j \) and using \( \bigcup_{k=1}^{n+1} A_k \) as a test set,

\[
\mu^*\left( \bigcup_{k=1}^{n+1} A_k \right) \geq \mu^*\left( \bigcup_{k=1}^{n} A_k \cap \bigcup_{k=1}^{n+1} A_k \right) + \mu^*\left( \bigcup_{k=1}^{n+1} A_k - \bigcup_{k=1}^{n} A_k \right) = \mu^*\left( \bigcup_{k=1}^{n} A_k \right) + \mu^* A_{n+1}.
\]

The induction hypothesis, \( \mu^*\left( \bigcup_{k=1}^{n} A_k \right) = \sum_{k=1}^{n} \mu^* A_k \) then implies

\[
\mu^*\left( \bigcup_{k=1}^{n+1} A_k \right) \geq \sum_{k=1}^{n+1} \mu^* A_k.
\]

This completes the induction proof. However, since for all \( n \),

\( \bigcup_{k=1}^{n} A_k \) is a subset of \( \bigcup_{k=1}^{\infty} A_k \),

\[
\mu^*\left( \bigcup_{k=1}^{\infty} A_k \right) \geq \mu^*\left( \bigcup_{k=1}^{n} A_k \right) = \sum_{k=1}^{n} \mu^* A_k.
\]

Since this is true for all \( n \),

\[
\mu^*\left( \bigcup_{k=1}^{\infty} A_k \right) \geq \sum_{k=1}^{\infty} \mu^* A_k.
\]

Since the union of the \( A_k \)'s is covered by \( A_1, A_2, \ldots \), from lemma 2.1.17

\[
\mu^*\left( \bigcup_{k=1}^{\infty} A_k \right) \leq \sum_{k=1}^{\infty} \mu^* A_k.
\]

Hence

\[
\mu^*\left( \bigcup_{k=1}^{\infty} A_k \right) = \sum_{k=1}^{\infty} \mu^* A_k.
\]
LEMMA 2.1.28

\( \mu^* \) restricted to \( B \) is unique.

Proof: First consider some \( B \) in \( B \) such that \( \mu^*B \) is finite. It is necessary to show that if \( \mu_1 \) is a measure on \( B \) such that \( \mu_1A \) equals \( \mu^*A \) equals \( \mu A \) for every \( A \) in \( C_2 \), then

\[
\mu_1B = \mu^*B.
\]

To show this equality consider that for every \( B \) in

\[
\mu^*B = \inf \sum_{i=1}^{\infty} \mu A_i.
\]

Hence for every \( \epsilon > 0 \), there exists a sequence \( A_1, A_2, \ldots \) in \( C_2 \) which covers \( B \) and is such that

\[
\mu^*B + \epsilon > \sum_{i=1}^{\infty} \mu A_i.
\]

Assuming the \( A_i \)'s are disjoint it follows that

\[
\sum_{i=1}^{\infty} \mu A_i = \sum_{i=1}^{\infty} \mu_1 A_i
\]

\[
= \mu_1(\bigcup_{i=1}^{\infty} A_i)
\]

\[
\geq \mu_1B.
\]

Hence

\[
\mu^*B \geq \mu_1B.
\]

To show the reverse inequality, consider that since \( B \) is in \( C_3 \),

\[
\mu^*(\bigcup_{i=1}^{\infty} A_i) \geq \mu^*(\bigcup_{i=1}^{\infty} A_i \cap B) + \mu^*(\bigcup_{i=1}^{\infty} A_i - B).
\]

\[
= \mu^*B + \mu^*(\bigcup_{i=1}^{\infty} A_i - B).
\]

27
Since the $A_i$'s are disjoint

$$
\epsilon > \sum_{i=1}^{\infty} \mu^k A_i - \mu^k B
$$

$$
= \mu^k (\bigcup_{i=1}^{\infty} A_i) - \mu^k B
$$

$$
= \mu^k (\bigcup_{i=1}^{\infty} A_i - B)
$$

But for every $\epsilon > 0$, there exists a sequence of sets $B_1, B_2, \cdots$ in $C_2$ that cover $\bigcup_{i=1}^{\infty} A_i - B$ and are such that

$$
\mu^k (\bigcup_{i=1}^{\infty} A_i - B) < \sum_{i=1}^{\infty} \mu B_i.
$$

Taking the $A_i$'s to be disjoint, it follows that

$$
\sum_{i=1}^{\infty} \mu B_i = \sum_{i=1}^{\infty} \mu B_i
$$

$$
\geq \mu_i (\bigcup_{i=1}^{\infty} A_i - B)
$$

Hence

$$
\mu_i (\bigcup_{i=1}^{\infty} A_i - B) < \epsilon + \mu^k (\bigcup_{i=1}^{\infty} A_i - B)
$$

$$
< \epsilon + \epsilon
$$

Furthermore

$$
\mu^k B \leq \mu^k (\bigcup_{i=1}^{\infty} A_i)
$$

$$
= \sum_{i=1}^{\infty} \mu^k A_i
$$
\[ \begin{align*}
&= \sum_{i=1}^{\infty} \mu_i A_i \\
&= \mu_1 \left( \bigcup_{i=1}^{\infty} A_i \right) \\
&= \mu_1 \left( \bigcup_{i=1}^{\infty} A_i - B \right) + \mu_i B \\
&< 2 \epsilon + \mu_i B.
\end{align*} \]

It follows that
\[ \mu^* B \leq \mu_1 B. \]

Hence
\[ \mu_1 B = \mu^* B. \]

Assuming \( \mu^* B \) is infinite, express \( R \) as the infinite union of bounded disjoint intervals. Then \( R = \bigcup_{i=1}^{\infty} (a_i, b_i] \).

Further \( B = B \cap \bigcup_{i=1}^{\infty} (a_i, b_i] \) and
\[ \begin{align*}
\mu^* B &= \sum_{i=1}^{\infty} \mu^* (B \cap (a_i, b_i]) \\
&= \sum_{i=1}^{\infty} \mu_1 (B \cap (a_i, b_i]) \\
&= \mu_1 B.
\end{align*} \]

**Theorem 2.2:**

If \( \mu \) is a Lebesgue-Stieltjes measure on \( \mathcal{B} \), then there exists a unique equivalence class \( M \) in \( \mathcal{E} \) such that for every \( F \) in \( M \) and every \( a \leq b \)
\[ \mu(a, b] = F(b) - F(a). \]
DEFINITION 2.2.1

\[ F(x) = \begin{cases} 
\mu(o,x] & \text{for } x > o \\
0 & \text{for } x = o \\
\mu(x,o] & \text{for } x < o 
\end{cases} \]

The proof of this theorem comes from the following lemmas:

**Lemma 2.2.1**

For every \( a < b \),

\[ \mu(a,b] = F_o(b) - F_o(a) \]

Proof: There are five cases:

Case 1: If \( o < a \),

\[ F_o(a) = \mu(o,a] \text{ and } F_o(b) = \mu(o,b] \]

However

\[ \mu(o,b] = \mu(o,a] + \mu(a,b] \]

It follows that

\[ F_o(b) - F_o(a) = \mu(a,b]. \]

Case 2: If \( o = a \),

\[ F_o(a) = 0 \text{ and } F_o(b) = \mu(o,b] = \mu(a,b] \]

Clearly

\[ F_o(b) - F_o(a) = \mu(a,b]. \]

The other three cases, when \( a < 0 < b \), \( b = 0 \) and \( a < b < o \), follow in a similar fashion.

**Lemma 2.2.2**

\( F_o \) is a monotone, non decreasing function defined for every \( x \) in \( R \).

Proof: For every \( x > a \)

\[ F_o(x) - F_o(a) = \mu(a,x]. \]
Since $\mu(a,x] \geq 0$, it follows that for every $x > a$

$$F_o(x) \geq F_o(a)$$

Since $a$ is chosen arbitrarily, $F_o$ is a monotone increasing function.

Clearly $F_o$ is defined for all $x$ in $\mathbb{R}$.

**Lemma 2.2.3**

$F_o$ is continuous from the right at every point of $\mathbb{R}$.

**Proof:** Select an arbitrary real number, $a$. Then

$$(a, a+1] = \bigcup_{i=1}^{\infty} (a + \frac{1}{i+1}, a + \frac{1}{i})$$

and

$$\mu(a, a+1] = \sum_{i=1}^{\infty} \mu(a + \frac{1}{i+1}, a + \frac{1}{i})$$

The sequence of partial sums represented by this infinite series is monotone increasing and bounded by $\mu(a, a+1]$. Hence for every $\epsilon > 0$ there exists an $N$ such that for every $n > N$

$$\sum_{i=n}^{\infty} \mu(a + \frac{1}{i+1}, a + \frac{1}{i}) < \epsilon.$$ 

However since

$$\mu(a, a + \frac{1}{n}] = \sum_{i=n}^{\infty} \mu(a + \frac{1}{i+1}, a + \frac{1}{i}),$$

it follows that

$$F_o(a + \frac{1}{n}) - F_o(a) < \epsilon$$

Since $F_o$ is monotone non-decreasing

$$F_o(x) - F_o(a) < \epsilon$$

for every $x$ in $(a, a + \frac{1}{n})$. Therefore $F_o$ is continuous on the right at $a$ where $a$ is an arbitrary real number.
LEMMA 2.2.4

$F_0$ is in $\mathcal{M}$.

DEFINITION 2.2.2

Let $M$ be the equivalence class in $\mathcal{M}$ which contains $F_0$.

LEMMA 2.2.5

For every $F$ in $M$ and every $a < b$,

$$\mu(a, b] = F(b) - F(a).$$

Proof: Since $F$ is in $M$, there exists a real number $C$ such that for every $x$ in $\mathbb{R}$,

$$F(x) = F_0(x) + C.$$

Thus

$$\mu(a, b] = F_0(b) - F_0(a) = F_0(b) + C - F_0(a) - C = F(b) - F(a).$$

This completes the proof of the theorem. The following is noted however:

LEMMA 2.2.6

$$\lim_{x \to a} \mu(x, a) = 0.$$

Proof: The proof is similar to the proof of lemma 2.2.3.
PART I: THE DEFINITION OF THE LEBESGUE-STIELJES INTEGRAL

The Lebesgue-Stieljes integral of a bounded point function \( g \) with respect to a Lebesgue-Stieljes measure \( \mu \), or with respect to any function \( F \) in the equivalence class of \( M \) that corresponds to \( \mu \) over a Borel set \( B \) such that \( \mu B \) is finite will be defined. The definition will be extended to functions \( g \) that are not bounded on \( B \), to Lebesgue-Stieljes measures \( \mu \) such that \( \mu B \) is infinite, to functions \( F \) that are monotone non-decreasing on \( R \) but not continuous on the right and finally to functions \( F \) of bounded variation on \( B \). Some preliminary definitions are necessary:

**DEFINITION 3.1.1**

For a given Borel set \( B \), \( D_n \) is defined to be a collection of \( n \) disjoint Borel sets \( B_1, B_2, \ldots, B_n \) such that

\[
\bigcup_{i=1}^{n} B_i = B.
\]

**DEFINITION 3.1.2**

The upper Darboux sum of a bounded function \( g \) with respect to a Lebesgue-Stieljes measure \( \mu \) and a given \( D_n \) on a Borel set \( B \) of finite \( \mu \)-measure is

\[
\sum_{i=1}^{n} M_i \mu B_i
\]

where \( B_1, B_2, \ldots, B_n \) are the elements of \( D_n \) and \( M_i \) is the supremum of \( g \) on \( B_i \).

**DEFINITION 3.1.3**

The lower Darboux sum of a bounded function \( g \) with respect to a Lebesgue-Stieljes measure \( \mu \) and with respect to a given \( D_n \) over a Borel
set \( B \) of finite \( \mu \)-measure is

\[
\sum_{i=1}^{\hat{n}} m_i \mu B_i
\]

where \( B_1, B_2, \ldots, B_n \) are the elements of \( D \) and \( M \) is the infimum of \( g \) on \( B_i \).

**DEFINITION 3.1.4**

The upper integral of a bounded function \( g \) with respect to a Lebesgue-Stieltjes measure \( \mu \) over a Borel set \( B \) of finite \( \mu \)-measure is

\[
\inf \sum_{i=1}^{n} M_i \mu B_i
\]

where the infimum is taken with respect to all \( D_n \)'s for all values of \( n \). The upper integral is denoted by

\[
\overline{\int_B g \, d\mu} \quad \text{or} \quad \overline{\int_B g \, dF}
\]

where \( F \) is any function in the equivalence class corresponding to \( \mu \).

**DEFINITION 3.1.5**

The lower integral of a bounded function \( g \) with respect to a Lebesgue-Stieltjes measure \( \mu \) over a Borel set \( B \) of finite \( \mu \)-measure is

\[
\sup \sum_{i=1}^{n} m_i \mu B_i
\]

where the supremum is taken with respect to all \( D_n \)'s for all values of \( n \). The lower integral is denoted by

\[
\underline{\int_B g \, d\mu} \quad \text{or} \quad \underline{\int_B g \, dF}
\]

where \( F \) is defined as in definition 3.1.4.

**DEFINITION 3.1**

A bounded function \( g \) is Lebesgue-Stieltjes integrable with respect to
the Lebesgue-Stieljes measure $\mu$ over a Borel set $B$ of finite $\mu$-measure if the upper and lower integrals are equal and finite. The common value of the upper and lower integrals is called the Lebesgue-Stieljes integral and is denoted by

$$\int_B g \, d\mu \quad \text{or} \quad \int_B g \, dF$$

**THEOREM 3.1:**

A necessary and sufficient condition for the existence of $\int_B g \, d\mu$ is that for every $\varepsilon > 0$, there exists a $D_n$ such that

$$\sum_{i=1}^{n} (M_i - m_i) \mu B_i < \varepsilon$$

Proof: Clearly each upper Darboux sum is greater than or equal to each lower Darboux sum. It follows that

$$\int_B g \, d\mu = \sum_{i=1}^{n} M_i \mu B_i$$

For every $\varepsilon > 0$ there exists a $D_n'$ and a $D_m''$ such that

$$\sum_{i=1}^{n} M_i \mu B_i - \int_B g \, d\mu < \varepsilon/2$$

and

$$\int_B g \, d\mu - \sum_{i=1}^{m} m_i \mu B_i < \varepsilon/2$$

These inequalities continue to hold when $D_n'$ and $D_m''$ are replaced by $D_k = \{ B_i \cap B_k', B_i \cap B_k'', \ldots, B_i \cap B_m' \}$. If $\int_B g \, d\mu$ exists, the upper and lower integrals are equal by definition. It follows that the stated condition is necessary. Conversely, if the condition is satisfied

$$\int_B g \, d\mu - \int_B g \, d\mu < \varepsilon$$
Since the inequalities hold for every \( \epsilon > 0 \) the upper and lower integrals must be equal.

**THEOREM 3.2:**

If \( \mu B \) is finite and \( g \) is Borel measurable and bounded on \( B \), the \( \int_B g \, d\mu \) exists.

**Proof:** Take \( \frac{\epsilon}{1 + \mu B} > 0 \) and any finite number of points 
\( y_0, y_1, \ldots, y_n \) such that

\[
\begin{align*}
y_0 &= \inf f(x) \quad \text{for all } x \in B, \\
y_n &= \sup f(x) \quad \text{for all } x \in B, \\
m &= y_0 < y_1 < \ldots < y_n = M,
\end{align*}
\]

and

\[
y_i - y_{i-1} < \frac{\epsilon}{1 + \mu B} \quad \text{for } i = 1, 2, \ldots, n.
\]

Let

\[
B_i = \left\{ x : x \in B \text{ and } y_{i-1} < g(x) \leq y_i \right\} = \left\{ x : x \in B \text{ and } g(x) \leq y_i \right\} \cap \left\{ x : x \in B \text{ and } g(x) > y_{i-1} \right\}
\]

Since \( g \) is Borel measurable, \( B_i \) is the intersection of two Borel sets and therefore a Borel set. It follows that \( \mu B_i \) is defined. If \( M_j \) is the supremum of \( g(x) \) for \( x \in B_i \) and \( m_i \) is the infimum of \( g(x) \) for \( x \in B_i \), it follows that

\[
y_{i-1} < m_i \leq g(x) \leq M_i \leq y_i.
\]

It follows that

\[
M_i - m_i < \frac{\epsilon}{1 + \mu B}.
\]
Therefore

\[ 0 \leq \sum_{i=1}^{n} (M_i - m_i) \mu B_i \]
\[ < \frac{\varepsilon}{1 + \mu B} \sum_{i=1}^{n} \mu B_i = \varepsilon \frac{\mu B}{1 + \mu B} < \varepsilon \]

It follows from theorem 3.1 that the Lebesgue-Stieljes integral exists.

**DEFINITION 3.2**

If \( g \) is not bounded on \( B \), define

\[
\int_B g \, d\mu = \lim_{b \to \infty} \int_B g_{a,b} \, d\mu
\]

where

\[
g_{a,b}(x) = \begin{cases} 
  a & \text{for } g(x) < a \\
  g(x) & \text{for } a \leq g(x) \leq b \\
  b & \text{for } b < g(x)
\end{cases}
\]

provided the above limit exists.

**DEFINITION 3.3**

If \( \mu B \) is infinite, define

\[
\int_B g \, d\mu = \lim_{b \to \infty} \int_{B_{a,b}} g \, d\mu
\]

where

\[
B_{a,b} = B \cap (a, b)
\]

provided the limit exists.

**DEFINITION 3.5**

If \( F \) is monotone non-decreasing but not continuous on the right, define
\[ \int_B q \, dF = \int_B q \, dF^* \]

where

\[ F^*(x) = \lim_{x' \to x} F(x') \]

for all \( x \) in \( B \) provided the integral with respect to \( F^* \) exists.

**DEFINITION 3.6**

If \( F \) is of bounded variation on \( R \), define

\[ \int_B q \, dF = \int_B q \, dF_1 - \int_B q \, dF_2 \]

where

\[ F = F_1 - F_2 \]

and \( F_1 \) and \( F_2 \) are monotone non-decreasing provided the integrals with respect to \( F_1 \) and \( F_2 \) exist.
PART II: PROPERTIES OF THE LEBESGUE-STIELJES INTEGRAL

Properties will be derived for the Lebesgue-Stieljes integral of a bounded Borel measurable function \( g \) with respect to a Lebesgue-Stieljes measure \( \mu \) over a Borel set \( B \) of finite \( \mu \) measure. These properties will be useful in Chapter 4.

**Theorem 3.3**

If \( g_1, \ldots, g_n \) is a finite collection of bounded Borel measurable functions,

\[
\int_B \left( \sum_{i=1}^{n} g_i \right) \, d\mu = \sum_{i=1}^{n} \int_B g_i \, d\mu
\]

Proof: Since \( g_1 \) and \( g_2 \) are bounded and Borel measurable, so is \( g_1 + g_2 \).

It follows that

\[
\int_B (g_1 + g_2) \, d\mu = \sup \sum_{i=1}^{n} m_{0i} \mu B_i
\]

\[
= \inf \sum_{i=1}^{n} M_{0i} \mu B_i
\]

where \( m_{0i} \) is the infimum of \( g_1(x) + g_2(x) \) for all \( x \) in \( B_i \) and \( M_{0i} \) is the supremum of \( g_1(x) + g_2(x) \) for all \( x \) in \( B_i \). Furthermore

\[
m_{1i} + m_{2i} \leq m_{0i}
\]

where \( m_{1i} \) is the infimum of \( g_1(x) \) and \( m_{2i} \) is the infimum of \( g_2(x) \) for all \( x \) in \( B_i \); moreover

\[
M_{1i} + M_{2i} \geq M_{0i}
\]

where \( M_{1i} \) and \( M_{2i} \) are defined in the obvious way. It follows that

\[
\sum_{i=1}^{n} m_{0i} \mu B_i \geq \sum_{i=1}^{n} (m_{1i} + m_{2i}) \mu B_i
\]
and

$$\sum_{i=1}^{n} M_{\alpha i} \mu B_i \leq \sum_{i=1}^{n} (M_{\alpha i} + M_{\beta i}) \mu B_i$$

Since $g_1$ and $g_2$ are integrable, it follows that

$$\int_B g_1 \, d\mu + \int_B g_2 \, d\mu = \sup \sum_{i=1}^{n} m_{\alpha i} \mu B_i + \sup \sum_{i=1}^{n} m_{\beta i} \mu B_i$$

$$= \sup \sum_{i=1}^{n} (m_{\alpha i} + m_{\beta i}) \mu B_i$$

$$= \inf \sum_{i=1}^{n} (M_{\alpha i} + M_{\beta i}) \mu B_i$$

But since

$$m_{\alpha i} + m_{\beta i} \leq M_{\alpha i} \leq M_{\alpha i} \leq M_{\alpha i} + M_{\beta i}$$

it follows that

$$\int_B g_1 \, d\mu + \int_B g_2 \, d\mu = \int_B (g_1 + g_2) \, d\mu$$

The conclusion follows by induction.

**Theorem 3.4**

If $B_1$ and $B_2$ are disjoint Borel sets of finite $\mu$-measure whose union is $B$, then

$$\int_B g \, d\mu = \int_{B_1} g \, d\mu + \int_{B_2} g \, d\mu$$

**Proof:** Define

$$g_1(x) = \begin{cases} g(x) & \text{for } x \in B_1 \\ 0 & \text{for } x \in B_2 \end{cases}$$

and

$$g_2(x) = \begin{cases} g(x) & \text{for } x \in B_2 \\ 0 & \text{for } x \in B_1 \end{cases}$$

40
Then

\[ \int_B g \, d\mu = \int_B (q_1 + q_2) \, d\mu \]
\[ = \int_{B_1} q_1 \, d\mu + \int_{B_2} q_2 \, d\mu \]
\[ = \int_{B_1} g \, d\mu + \int_{B_2} g \, d\mu. \]

**THEOREM 3.5**

\[ m\mu B \leq \int_B g \, d\mu \leq M\mu B \]

where \( m \) is the infimum and \( M \), the supremum of \( g(x) \) for all \( x \) in \( B \).

Proof: Letting \( B_1, B_2, \ldots, B_n \) be a sequence of disjoint Borel sets whose union is \( B \) and letting \( M_i \) be the supremum of \( g(x) \) for all \( x \) in \( B_i \), it follows that \( M_i \leq M \) for all \( i \). Thus

\[ \sum_{i=1}^{\infty} M_i \mu B_i \leq \sum_{i=1}^{\infty} M \mu B_i \]
\[ = M \mu B. \]

Similarly

\[ \sum_{i=1}^{\infty} m_i \mu B_i \leq m \mu B. \]

But when the Lebesgue-Stieljes integral exists

\[ \inf \sum_{i=1}^{\infty} M_i \mu B_i = \sup \sum_{i=1}^{\infty} m_i \mu B_i. \]

It follows that

\[ m \mu B \leq \int_B g \, d\mu \leq M \mu B. \]
COROLLARY 3.5.1

If \( \mu_B = 0 \), \( \int_B g \, d\mu = 0 \)

THEOREM 3.6

\[ |\int_B g \, d\mu| \leq \int_B |g| \, d\mu. \]

Proof: Clearly

\[ |g(x)| + g(x) \geq 0 \quad \text{and} \quad |g(x)| - g(x) \geq 0 \]

Letting \( m_1 \) be the infimum of \(|g(x)| + g(x)\) for all \( x \) in \( B \) and \( m_2 \), the infimum of \(|g(x)| - g(x)\), it follows that

\[ 0 \leq m_1 \mu_B \]
\[ \leq \int_B (|g| + g) \, d\mu \]
\[ = \int_B |g| \, d\mu + \int_B g \, d\mu. \]

Hence

\[ -\int_B g \, d\mu \leq \int_B |g| \, d\mu \]

Similarly

\[ 0 \leq m_2 \mu_B \]
\[ \leq \int_B (|g| - g) \, d\mu \]
\[ = \int_B |g| \, d\mu + \int_B (-g) \, d\mu. \]

Since it follows directly from the definition that a constant may be factored across the integral sign,

\[ \int_B g \, d\mu \leq \int_B |g| \, d\mu. \]

Hence

\[ |\int_B g \, d\mu| \leq \int_B |g| \, d\mu. \]
Suppose $\mu$ is a Lebesgue-Stieljes measure, $B$ is some Borel set of finite $\mu$-measure and $g_1, g_2, \cdots$ is a sequence of Borel measurable functions defined on $B$ and such that for every $n$ and for every $x$ in $B$ there exists a real number $K$ such that

$$|g_n(x)| < K$$

Suppose moreover that

$$\lim_{n \to \infty} g_n(x) = g(x)$$

almost everywhere i.e., for all $x$ in $B-B_0$ where $\mu B_0 = 0$. Finally suppose that $g$ is bounded on $B$. It follows that

$$\lim_{n \to \infty} \int_B g_n \, d\mu = \int_B \lim_{n \to \infty} g_n \, d\mu$$

**Proof:** Since $g$ is bounded on $B$ and $\mu B_0 = 0$, it is obvious that

$$\int_{B_0} g \, d\mu = 0$$

Letting $B-B_0 = B^*$, $g$ is the limit of a sequence of Borel measurable functions on $B^*$ and hence $g$ is Borel measurable. Moreover $|g(x)| \leq K$ for all $x$ in $B^*$. It follows that $g(x)$ is integrable over $B^*$ and hence the following integrals exist and

$$\int_{B^*} g \, d\mu = \int_{B^*} g \, d\mu + \int_{B_0} g \, d\mu$$

$$= \int_B g \, d\mu.$$
\[ B_i = \{ x : |q_n(x) - q(x)| < \varepsilon \text{ for } n = 1, 2, \ldots \} \]

\[ B_2 = \{ x : |q_n(x) - q(x)| < \varepsilon \text{ for } n = 2, 3, \ldots \} \]

\[ \ldots \]

\[ B_\infty = \{ x : |q_n(x) - q(x)| < \varepsilon \text{ for } n = i, i+1, \ldots \} \]

where \( \varepsilon = \frac{\varepsilon}{2(1+\mu B)} \)

Since \( B_i \) is a subset of \( B^* \) for every \( i \)

\[ \bigcup_{i=1}^{\infty} B_i \subseteq B^* \]

Furthermore, \( x \) in \( B^* \) implies \( \lim_{n \to \infty} g_n(x) \) equals \( g(x) \). This means that for every \( \varepsilon > 0 \) there exists an \( m \) such that for every \( n > m \), \( x \) is in \( B_n \).

In symbols

\[ B^* \subseteq \bigcup_{x=1}^{\infty} B_x \]

It follows that

\[ B^* = \bigcup_{x=1}^{\infty} B_x \]

Since \( B_1 \subseteq B_2 \subseteq \ldots \),

\[ \bigcup_{x=1}^{\infty} B_x = B_1 \cup \bigcup_{x=1}^{\infty} (B_{x+1} - B_x) \]

Thus since the sets on the right are disjoint Borel sets
This means that there exists an \( m \) such that for every \( n > m \)

\[
| \mu B - \mu B_n | < \frac{\varepsilon}{4K}
\]

Since it may be easily shown that \( | g_n - g | \) is a bounded, Borel measurable function, it follows that \( | g_n - g | \) is integrable and hence for every \( n > m \)

\[
\int_B | g_n - g | \, d\mu = \int_{B_n} | g_n - g | \, d\mu + \int_{B-B_n} | g - g_n | \, d\mu
\]

\[
< \varepsilon \mu B_n + 2K \mu (B-B_n)
\]

\[
< \frac{\varepsilon \mu B}{2(1+\mu e)} + 2K \frac{\varepsilon}{4K} < \varepsilon.
\]

Since

\[
| \int_B (g_n - g) \, d\mu | \leq \int_B |g_n - g| \, d\mu,
\]

it follows that for every \( \varepsilon > 0 \), there exists an \( m \) such that for every \( n > m \).
THEOREM 3.8

If \[ \sum_{\ell=1}^{\infty} f_{\ell}(x) = q(x) \] almost everywhere on some Borel set \( B \) of infinite \( \mu \)-measure, if \( g \) is bounded on \( B \) and if there exists a real number \( K \) such that for all \( x \) in \( B \) and for all \( n \), \[ | \sum_{\ell=1}^{n} f_{\ell}(x) | < K \] then

\[ \sum_{\ell=1}^{\infty} \int_{B} f_{\ell} \, d\mu = \int_{B} \left( \sum_{\ell=1}^{\infty} f_{\ell} \right) \, d\mu. \]

Proof: This is an immediate consequence of theorem 3.7 considering the sequence of partial sums.

THEOREM 3.9

If \( B_1, B_2, \ldots \) is a sequence of disjoint Borel sets whose union is \( B \),

\[ \int_{B} q \, d\mu = \sum_{\ell=1}^{\infty} \int_{B_\ell} q \, d\mu. \]

Proof: Define \( e_\ell(x) \) to be 1 when \( x \) is in \( B_\ell \) and zero otherwise. Then for all \( x \) in \( B \),

\[ q(x) = \sum_{\ell=1}^{\infty} e_\ell(x) q(x). \]

Hence

\[ \int_{B} q \, d\mu = \int_{B} \left( \sum_{\ell=1}^{\infty} e_\ell q \right) \, d\mu \\
= \sum_{\ell=1}^{\infty} \int_{B} e_\ell q \, d\mu \\
= \sum_{\ell=1}^{\infty} \int_{B_\ell} q \, d\mu. \]
Chapter 4

PROBABILITY INTEGRALS

In this section probability measure and probability distribution function will be defined. Then it will be shown how the Lebesgue-Stieljes integral of a bounded Borel measurable function \( g \) with respect to a probability measure may be expressed as a countable sum of positive numbers plus the Lebesgue-Stieljes integral of \( g \) with respect to a function that is everywhere continuous.

**DEFINITION 4.1**

If \( F \) is monotone non-decreasing, defined on \( \mathbb{R} \) and continuous from the right, i.e. if \( F \) is an element of \( \mathcal{M} \) and if \( \lim_{x \to -\infty} F(x) = 0 \) and \( \lim_{x \to +\infty} F(x) = 1 \), then \( F \) is a probability distribution function.

**DEFINITION 4.2**

If \( \mu \) is the unique measure determined by a probability distribution function, \( \mu \) is a probability measure and for any Borel set \( B \), \( \mu B \) will be denoted by \( P(B) \). \( P(B) \) is the "probability" that \( x \) is in \( B \).

**THEOREM 4.1**

If \( P \) is a probability measure,

Moreover for all Borel sets \( B \),

**THEOREM 4.2**

If \( \mu \) is a Lebesgue-Stieljes measure, \( \mu \{ a \} \) is greater than zero if and only if \( a \) is a point of discontinuity for every function \( F \) in the equivalence class corresponding to \( \mu \).
Proof: First assuming that \( a \) is a point of discontinuity, it follows from the fact that every \( F \) is monotone non-decreasing and continuous on the right that

\[
\lim_{x \to a^-} F(x) < \lim_{x \to a^+} F(x) = F(a).
\]

But

\[
\lim_{x \to a^-} \mu(x, a) = \lim_{x \to a^-} \mu(x, a) + \mu \{a\} = \mu \{a\}
\]

Further

\[
\lim_{x \to a^-} \mu(x, a) = \lim_{x \to a^-} (F(a) - F(x)) > 0
\]

It follows that \( \mu \{a\} > 0 \)

On the other hand, assuming that \( \mu \{a\} > 0 \)

\[
\lim_{x \to a^-} (F(a) - F(x)) = \mu \{a\} > 0
\]

Hence \( F \) is discontinuous at \( a \). This clearly holds for all \( F \) in the equivalence class corresponding to \( \mu \).

**COROLLARY 4.2.1**

\[
\mu \{a\} = 0 \quad \text{if and only if } a \text{ is a point of continuity of } F \text{ for all } F \text{ in the equivalence class corresponding to } \mu.
\]

**THEOREM 4.3**

For all functions \( F \) in \( M \) there are at most a countable number of discontinuities.

**Proof:** Suppose \( a \) is a point of discontinuity for \( F \). Then

\[
F(a) = \lim_{x \to a^+} F(x) > \lim_{x \to a^-} F(x).
\]

48
Mate a with a rational number \( r \) such that
\[
\lim_{x \to a^-} F(x) < r < \lim_{x \to a^+} F(x).
\]

Since \( F \) is monotone non-decreasing, each distinct point of discontinuity corresponds to a distinct rational number. Since the rationals are denumerable, the points of discontinuity are countable.

**Theorem 4.4**

If \( F \) is a probability distribution function

\[
F = f + S
\]

where \( f \) is continuous on \( R \).

Proof: Let \( \overline{x} \) be the points of discontinuity for \( F \). \( \overline{x} \) is a Borel set since \( \overline{x} \) is a countable union of distinct points and each point is a Borel set. Moreover, \( R - \overline{x} \) is the points of continuity for \( F \) and is also a Borel set. Suppose \( P \) is the probability measure that corresponds to \( F \).

Then for all Borel sets \( B \),
\[
P(B) = P(B \cap \overline{x}) + P(B - \overline{x})
\]

Define
\[
\mu_1 B = P(B - \overline{x}) \text{ and } \mu_2 B = P(B \cap \overline{x})
\]

Then \( \mu_1 \) and \( \mu_2 \) are bounded Lebesgue-Stieltjes measures. For all \( x \) define
\[
f(x) = \mu_1(-\infty, x] \text{ and } S(x) = \mu_2(-\infty, x].
\]

Then \( f \) is in the equivalence class corresponding to \( \mu_1 \) and \( S \) is in the equivalence class corresponding to \( \mu_2 \).

Then for all \( x \),

49
\[ f(x) + S(x) = \mu_1(-\infty, x] + \mu_2(-\infty, x] \]
\[ = \mathcal{P}(-\infty, x] - \mathcal{X} + \mathcal{P}([-\infty, x) \cap \mathcal{X}] \]
\[ = \mathcal{P}(-\infty, x] \]
\[ = \mathcal{P}(x) \]

If \( x \) is in \( \mathcal{X} \),

\[ \mu_1\{x\} = \mathcal{P}\{x\} - \mathcal{X} = \mathcal{P}\emptyset = 0 \]

If \( x \) is in \( \mathbb{R} - \mathcal{X} \)

\[ \mu_1\{x\} = \mathcal{P}\{x\} - \mathcal{X} = \mathcal{P}\{x\} = 0 \]

Hence \( \mu_1\{x\} \) is zero for all \( x \) in \( \mathbb{R} \). Since \( f \) is in the equivalence class corresponding to \( \mu_1 \) it follows that \( f \) is continuous for all \( x \).

**Theorem 4.5**

If \( x_1 \) and \( x_2 \) are two points in \( \mathcal{X} \) and no points of \( \mathcal{X} \) are in \( (x_1, x_2) \),

Then for every \( x \) in \( [x_1, x_2) \), \( S(x) = S(x_1) \).

**Proof:** For every \( x \) in \( [x_1, x_2) \),

\[ \mathcal{P}([-\infty, x] \cap \mathcal{X}) = \mathcal{P}([-\infty, x] \cap \mathcal{X}) + \mathcal{P}([x_1, x) \cap \mathcal{X}] \]
\[ = \mathcal{P}([-\infty, x] \cap \mathcal{X}) \]

Hence

\[ \mathcal{P}([-\infty, x] \cap \mathcal{X}) = \mu_2(-\infty, x] \]
\[ = S(x) = S(x_1) \).

**Theorem 4.6**

\( S \) is continuous at all \( x \) in \( \mathbb{R} - \mathcal{X} \) and discontinuous at \( x \) in \( \mathcal{X} \).
Proof: For $x$ in $\mathbb{R} - \overline{x}$,

$$\mu_2 \{x\} = \mathcal{P} \{ \{x\} \cap \overline{x} \} = \mathcal{P} \emptyset = 0$$

Hence $x$ is a point of continuity for $S$.

For $x$ in $\overline{x}$

$$\mu_2 \{x\} = \mathcal{P} \{ \{x\} \cap \overline{x} \} = \mathcal{P} \{x\} > 0$$

Hence $x$ is a point of discontinuity for $S$.

**DEFINITION 4.3**

A function having the properties attributed to $S$ in theorems 4.5 and 4.6 will be called a generalized step function.

**THEOREM 4.7**

$$\int_B g \, dF = \sum_{x_i \in B} g(x_i) \mu_2 \{x_i\} + \int_{\overline{B}} g \, d\mu_1$$

where $g$ is bounded and Borel measurable on the Borel set $B$, $F$ is a probability distribution function and $\overline{B}$, $\mu_1$ and $\mu_2$ are as defined in theorem 4.4.

Proof: By definition

$$\int_B g \, dF = \inf \sum_{i=1}^n M_i \mathcal{P}(B_i)$$

$$= \inf \sum_{i=1}^n M_i \left[ \mu_1 B_i + \mu_2 B_i \right]$$

$$= \inf \sum_{i=1}^n M_i \mu_1 B_i + \inf \sum_{i=1}^n M_i \mu_2 B_i.$$

---

51
\[= S_B g \, d\mu_2 + S_B g \, d\mu_1\]

From theorem 3.9

\[S_B g \, dF = \sum_{x_2 \in \text{in } B^{n \times 2}} [S_{\{x_2\}} g \, d\mu_2] + S_B g \, d\mu_1\]

\[= \sum_{x_2 \in \text{in } B^{n \times 2}} q(x_2) \mu_2(x_2) + S_B g \, d\mu_1\]
Chapter 5

CONCLUSION

A bounded Borel measurable function which gives an important special case of the general formulas in the preceding chapters is \( g(x) = 1 \) for all \( x \). If \( g(x) = 1 \), for any Borel set, \( B \), and any probability distribution function, \( F \), the probability that \( x \) is in \( B \) is given by

\[
\mathbb{P}(B) = \int_B dF
\]

Suppose \( F \) is continuous everywhere. It may be shown that \( F \) has a derivative at every point with the possible exception of a set of Lebesgue measure zero \([2]\). If the derivative of \( F, F' \), exists everywhere, it is called the probability density function. Furthermore it may be shown that

\[
\int_B F' \, dx = \int_B dF = \mathbb{P}(B).
\]

In particular, if \( B \) is the interval from \( a \) to \( b \)

\[
\mathbb{P}(B) = \int_a^b F' \, dx = F(b) - F(a)
\]

This is true regardless of whether the interval is \((a, b), (a, b], [a, b)\) or \([a, b] \). If \( B \) is a single point \( \mathbb{P}(B) \) is clearly zero.

Suppose \( F \) is a generalized step function, i.e. \( F(x) = S(x) \). The set of points at which \( F \) is discontinuous \( \overline{x} \) is either a finite or denumerable set. The function \( p \) is called the probability density function for \( F \) where

\[
p(x_2) = F(x_2) - \lim_{x \to x_2^-} F(x) \quad \text{for } x_2 \text{ in } \overline{x}
\]

and

\[
p(x) = 0 \quad \text{for } x \text{ not in } \overline{x}.
\]
The probability that \( x \) is in a Borel set \( B \) is

\[
\sum_{x_i \in B} \rho(x_i)
\]

The set \( X \) may be such that every point of \( X \) is in an interval containing no other points of \( X \). In this case \( X \) is said to be discrete. The discrete case includes the case where \( X \) has a finite number of points in every finite interval. In this case \( F \) is a step function in the ordinary sense \([3]\). It may also happen that \( X \) is discrete but has a denumerable number of points in some finite interval. For example let

\[
X = \{1, \frac{1}{2}, \frac{1}{3}, \ldots \}
\]

and define

\[
F(x) = \begin{cases} 
0 & \text{for } x \leq 1, \\
\frac{1}{2^n} & \text{for } x \in \left[ \frac{1}{n+1}, \frac{1}{n} \right), n=1,2,\ldots, \\
1 & \text{for } x \in [1, \infty).
\end{cases}
\]

Also the set \( X \) may be such that there exists a denumerable set of \( x_i \)'s in every interval. In this case \( X \) is said to be everywhere dense. For example let \( X \) be the set of all rational numbers, \( r_1, r_2, \ldots \). Define

\[
\rho(r_n) = \frac{1}{2^n}
\]

and let

\[
F(x) = \sum_{r_n \leq x} \rho(r_n)
\]

Finally \( F \) may of course be the sum of a non zero continuous function and a non zero generalized step function.

The two cases usually discussed in elementary probability courses are where \( F \) is everywhere differentiable (and hence continuous), and where \( F \) is an ordinary step function.
