AN EFFICIENCY FUNCTION FOR RATING
MECHANICAL SCAN-TRACK RADARS

ABSTRACT

A function, \( P_d \), introduced in ESD-TDR-63-292, is derived as a measure of effectiveness in rating certain mechanical scan-track radar configurations in the joint performance of two operational requirements. These are:

1. confirmation, i.e., acquisition and tracking of objects (missiles and/or satellites) detected by collocated surveillance radars, and
2. scanning, i.e., providing additional surveillance coverage for a missile threat in a sector not searched by the collocated surveillance radars.

We are mainly interested in the application of the \( P_d \) function to the problems of selecting a suitable scan-track radar for BMEWS Site II service. It is thought, however, that the function would be of general interest to others with similar problems of selection under joint operating constraints.

REVIEW AND APPROVAL

Publication of this technical documentary report does not constitute Air Force approval of the reports findings or conclusions. It is published only for the exchange and stimulation of ideas.

and Control Systems
AN EFFICIENCY FUNCTION FOR RATING MECHANICAL SCAN-TRACK RADARS

The $P_d$ function provides a measure of effectiveness for rating various mechanical scan-track radars in their hypothetical performance of two operational requirements: confirmation and scanning. Each scan-track radar is identified in terms of three pedestal parameters:

1. $V_s$ or azimuth scan velocity,
2. $V_m$ or maximum azimuth (slew) velocity, and
3. $a$, or maximum acceleration.

This report concerns the ability of a radar under test to confirm (i.e., acquire and track) targets detected by surveillance radars operating in an azimuth sector of width $A^\circ$ while maintaining scan surveillance for a target threat in an adjacent azimuth sector of width $B^\circ$. It is assumed that detections in the $A^\circ$ sector, and, hence, scan-track radar confirming or tracking assignments, occur at periodic intervals. It is further assumed that when the target threat (a missile raid) occurs, it occurs in the $B^\circ$ azimuth sector and remains within the surveillance volume for a period of $W$ seconds.

The logic for the scanning requirement for each scan-track radar under test is rigid and consists of following each confirmation task in the $A^\circ$ sector by at least two complete scans of the $B^\circ$ sector before accepting the next confirmation assignment. The efficiency of the various test radars, is computed based on their ability to fulfill the scanning requirement such that during the scan cycle at least two successive radar scans are obtained on one target during the raid passage time of $W$ seconds.
There are three time intervals necessary for the formulation of $P_d$:

1. $T_S$, or time to complete two scans of the $B^o$ sector. This quantity may be computed in terms of $V_S$ and $a$ as follows:

   $$T_S = \frac{2B^o}{V_S} + \frac{2V_S}{a}$$

2. $T_D$, or the average time to obtain two successive radar contacts on a target occurring in the $B^o$ sector. This time interval, as computed in the appendix to this report, is

   $$T_D = \frac{3B^o}{2V_S} + \frac{3V_S}{a}$$

3. $T_A$, or the time to confirm, i.e., acquire and track, a detected object in the $A^o$ sector and return to scan in the $B^o$ sector. The time increment necessary for acquiring the target and return to scan, $T_{ACQ+R}$ (exclusive of track time period), is given as $[1]$

   $$T_{ACQ+R} = \frac{V_S^2}{aV_m} + \frac{2V_m}{a} + \frac{2\Delta \theta}{V_m} - \frac{V_S}{a}$$

In this equation, $\Delta \theta$ is the azimuthal angular difference between radar beam position in scan ($B^o$ sector) and the position of the target to be confirmed in the $A^o$ sector. The definition of $T_A$ is completed by the addition of a tracking time interval of $\gamma$ seconds to $T_{ACQ+R}$.

---

Thus

\[ T_A = T_{ACQ+R} + \gamma = \frac{V^2}{S} \frac{V}{aV_m} + \frac{2m}{a} + \frac{2A\theta}{a} - \frac{V_S}{a} + \gamma. \]

In addition to the preceding definitions, the following inequalities are useful:

(1) If \( W < T_D \), then the scan-track radar will not, on the average, obtain two successive radar scans on a target in the \( B^0 \) sector. In this case we will say that \( P_d \approx 0 \); i.e., the measure of effectiveness of the radar with \( T_D > W \) should be a minimum value of approximately zero.

(2) If \( W > 2T_D + T_A \), then the scan track radar will, on the average, obtain at least two successive radar scans on the target in the \( B^0 \) sector, even after having performed a confirmation assignment of length \( T_A \). In this case we will say that \( P_d \approx 1 \); i.e., the measure of efficiency of the radar should be a maximum value of approximately unity.

These two inequalities serve to establish the class of scan-track radars that may be ranked in efficiency of performance by the function \( P_d \). Thus, if a candidate radar has pedestal parameters such that \( T_D > W \) or \( 2T_D + T_A < W \), then it is not an element of the class whose efficiency may be measured by \( P_d \). Conversely, if a candidate has pedestal parameters such that \( 2T_D + T_A > W > T_D \), then it is an element of the class whose efficiency can be measured by the \( P_d \) function. Further, the inequalities are used to establish that the operating range of \( P_d \) is in the interval \((0,1)\). Thus, if \( P_d \leq 0 \), we arbitrarily assign \( P_d = 0 \), while if \( P_d \geq 1 \), we assign \( P_d = 1 \).
We now proceed to derive $P_d$. Consider the unit time interval $T = T_A + T_S$ shown in Figure 1. If an event (raid of time duration $W$) commences in the time interval $(0, T_S - T_D)$, then the scan-track radar will obtain the necessary two scans on the target before being assigned to the confirmation task of length $T_A$.

During this interval, the radar is operating efficiently. However, if the event commences in the interval $(T_S - T_D, T_S + T_A - W + T_D)$, then no opportunity exists for obtaining the necessary scans on the target. During this interval, the radar is not operating efficiently. Finally, if the event commences during the interval $(T_S + T_A - W + T_D, T_S + T_D)$, then at least a $T_D$ portion of $W$ will carry over to the succeeding portion of $T_S$ in the next
unit period $T$. In this case, the necessary radar scans on at least one missile in the raid will be obtained, and the radar is operating efficiently in this interval. Summing the efficient intervals and obtaining a ratio with respect to the basic unit $T$ produces a formula for computing $P_d$:

$$P_d = \frac{W - 2T_D + T_S}{T} = \frac{W - 2T_D + T_S}{T_S + T_A}.$$ 

Application of the limiting values for $P_d$ noted earlier gives the complete function as

$$P_d = \begin{cases} 
W - 2T_D + T_S, & 0, \frac{W - 2T_D + T_S}{T_S + T_A} < 0 \\
\xi, & 0 \leq \xi \leq 1 \\
1, \frac{W - 2T_D + T_S}{T_S + T_A} > 1 
\end{cases}$$

This function can be computed by substituting values for the time intervals $T_S$, $T_D$, $T_A$ noted to test the consistency of the result with the inequalities $W < T_D$ and $W > 2T_D + T_A$ and to gain some insight into the ability of the $P_d$ function to operate as the desired measure of effectiveness of a scan-track radar.
The consistency of \( W > 2T_D + T_A \) and \( P_d \approx 1 \) can be shown by letting \( W = 2T_D + T_A + \epsilon, \ \epsilon > 0 \), substituting in \( P_d \), and solving:

\[
P_d = \frac{W - 2T_D + T_S}{T_S + T_A} = \frac{T_A + T_S + \epsilon}{T_A + T_S} > 1,
\]

or, by our convention, \( P_d = 1 \). Thus, at least for large values of \( W \), we find that \( P_d \) does exhibit the required measure characteristic.

In order to test the consistency of \( W < T_D \) and \( P_d \approx 0 \), let \( W = T_D - \epsilon, \ \epsilon > 0 \). Then

\[
P_d \times (T_S + T_A) \approx 0 \Rightarrow T_D - \epsilon - 2T_D + T_S,
\]

\[
0 \approx T_S - T_D - \epsilon
\]

Substitution of the computed values for \( T_S \) and \( T_D \) noted earlier yields

\[
\frac{B^0}{2V_S} - \frac{V_S}{a} - \epsilon \approx 0.
\]

Letting \( \epsilon \to 0 \), i.e., \( W \to T_D \), we obtain the approximate condition under which the inequality \( W < T_D \) implies that \( P_d \approx 0 \):

\[
B^0 \approx \frac{2V_S^2}{a}.
\]

This implication of this condition is clear. For \( V_S > 0, \ a > 0, \) there is only a point value, \( V_S^1 = \sqrt[2]{\frac{B^0}{a}} \), where \( P_d \approx 0 \). For \( V_S > V_S^1 \), we compute \( P_d < 0 \), or, by our convention, \( P_d = 0 \). However, for \( V_S < V_S^1 \), we compute
$P_d > 0$, and our assumption that $W < T D \rightarrow \frac{P_D}{P_d} \approx 0$ is inconsistent with this result.

A calculation will help to illustrate the inconsistency.

Let

$$B^0 = 50^\circ, \ V_S = 10 \text{ deg/sec}, \text{ and } a = 36 \text{ deg/sec}^2.$$ 

Then

$$V_S = 10^\circ < V^1_S = 5(\text{deg})^{1/2} a^{1/2} = 30 \text{ deg/sec} \text{ and }$$

$$P_d \times (T_S + T_A) \approx T_S - T_D - \epsilon$$

$$\approx \frac{25 \text{ deg}}{10 \text{ deg/sec}} - \frac{10 \text{ deg/sec}}{36 \text{ deg/sec}} - \epsilon \approx 2.5 \text{ sec} - 0.25 \text{ sec}$$

Thus

$$P_d \approx \frac{2.5 \text{ sec} - 0.25 \text{ sec}}{T_S + T_A} > 0,$$

and, in this case, $W < T_D \neq P_D \approx 0$. The reason for this inconsistency is found in the definition of $T_D$ as an average quantity, whereas its use in the formulation of $P_d$ was as a deterministic for fixed quantity such as $T_S$. Thus, the $P_d$ function as defined is probably inadequate for ranking of radars with efficiency ratings of approximately zero. Since this use of the function would not occur in the usual investigation of efficiency of operation, it will not be considered further.

We next consider the versatility of the $P_d$ function. Up to this point, the advantage of $P_d$ in the rating of competitive radars systems which perform a dual operational service has been stressed. This was the use of the function in ESD-TDR-63–292, where three field service units were ranked to indicate the most efficient unit for the dual requirement. During that computation it was found that the most efficient unit actually exceeded the requirements in the sense that the computed value of $P_d$ exceeded unity.
This indicated that an interpolation between the pedestal parameters of the most efficient and nearest competitor unit would provide a description of an optimum solution; i.e., a radar matched to the condition \( P_d = 1 \). This was computed and presented as the suggested minimum solution for an efficient radar that met the joint operational requirement.

Subsequent to that solution, it was realized that the \( P_d \) function offered a much more general vehicle for the examination of the interplay between pedestal parameters and operation requirements. This can be seen by evaluating \( P_d \) in terms of these quantities. Let, as was the case in TDR-63-292, \( A^\circ = 120^\circ \), \( B^\circ = 50^\circ \), \( \gamma = 10 \text{ sec} \). Then

\[
P_d = \frac{W - 2T_D + T_S}{T_S + T_A}
\]

Consolidation of this expression gives

\[
P_d = \frac{W - \frac{50^\circ}{V_S} - \frac{4V_S}{a}}{\frac{V_S^2}{aV_m} + \frac{2V_m}{a} + \frac{2\Delta \theta}{V_m} + \frac{V_S}{a} + 10 + \frac{100^\circ}{V_S} + \frac{2V_S}{a}}
\]

With \( \Delta \theta = 85^\circ \) and \( W = 40 \text{ sec} \) (as in TDR-63-292) we obtain
Since we are mainly concerned with efficient radar units, we set $P_d = 1$ to obtain the general function relating pedestal parameters to operational requirements:

$$
P_d = \frac{40 - \frac{50^\circ}{V_S} - 4 \frac{V_S}{a}}{\frac{V^2}{aV_m} + \frac{2V_m}{a} + \frac{170^\circ}{V_m} + \frac{V_S}{a} + \frac{100^\circ}{V_S} + 10}
$$

A plot of this function is shown in Figure 2, where a family of solutions is presented for various fixed values of $V_S$. The optimum solution of ESD–TDR–63–292 is just within the contour of $(V_m, a)$ for $V_S = 10$ deg/sec. Actually, the solution is just within the region ($R_1$) bounded by the contour, and this implies a slight over-achievement of the operational requirement; i.e., the computed value of $P_d + 1 + \epsilon$, where $\epsilon$ is small. Solutions occurring to the left of the contour in region $R_2$ would indicate that the computed value of $P_d < 1$. For $V_S < 10^\circ$, generally larger values of the pair $(V_m, a)$ are necessary to obtain equal efficiency (i.e., $P_d = 1$) than those necessary for the case $V_S = 10^\circ$. Specifically, for any choice of $V_m$ (or $a$) the coordinate $a$ (or $V_m$) for the case $V_S = 10^\circ$ is less than the same coordinate value for $V_S < 10^\circ$ when $P_d = 1$. Further when $V_S > 10.7$ deg/sec, $V_m < 10.7$ deg/sec. Thus, for high scan rates in the $B^\circ$ sector, the slew velocity needed to confirm a target in the $A^\circ$ sector can be eased to a level
Figure 2. The Relationship of Pedestal Parameters to Operational Requirements for \( P_d = 1 \).
below the scan rate. Since this conclusion disagrees with our physical interpretation of slew velocity as a quantity greater than scan velocity, the case where $V_m < V_S$ has not been investigated.

The investigation of the $P_d$ function is concluded with one further computation. For fixed values of $V_S$ and $P_d = 1$, it is possible to relate $V_m$ and $a$:

$$W - \frac{B^o}{V_S} - \frac{4V_S}{a} = \frac{V_S^2}{aV_m} + \frac{2V_m}{a} + \frac{2\Delta \theta}{V_m} + \frac{V_S}{a} + \gamma + \frac{2B^o}{V_S},$$

$$a = \frac{V_S^2}{V_m} + \frac{2V_m}{V_S} + \frac{5V_S}{V_m},$$

$$W - \frac{3B^o}{V_S} - \frac{2\Delta \theta}{V_m} - \gamma.$$

Since both $V_m$ and $a$ are greater than zero, then the denominator

$$W - \frac{3B^o}{V_S} - \frac{2\Delta \theta}{V_m} - \gamma > 0.$$ 

If we replace the inequality with an equality by adding a small quantity $\epsilon > 0$ to the right-hand side, we obtain

$$W - \frac{3B^o}{V_S} - \frac{2\Delta \theta}{V_m} - \gamma = \epsilon.$$

Addition of $(2\Delta \theta/V_m)$ to this expression, produces the approximate equality
\[ V_m \approx \frac{2 \Delta \theta}{W - \frac{3B^0}{V_S} - \gamma} \]

Substitution of the values \( \Delta \theta = 85^\circ \), \( B^0 = 50^\circ \), \( \gamma = 10 \text{ sec} \), and \( W = 40 \text{ sec} \), and setting \( V_S = 10 \text{ deg/sec} \), we obtain

\[ V_m \approx \frac{170 \text{ deg}}{15 \text{ sec}} = 12 \text{ deg/sec} \]

This specific solution of \( V_m \) is an approximate minimum value solution. As shown in Figure 2, for the specified conditions only values larger than \( V_m = 12 \text{ deg/sec} \) are possible. Thus, the \( P_d \) function can be used to obtain rough values of the minimum value of slew velocity for given fixed \( V_S \).
APPENDIX

COMPUTATION OF TIME PERIOD $T_D$

The time period $T_D$ is defined as the average time to obtain two successive radar contacts or scans on a target occurring in the $B^\circ$ sector. For the first such scan, let $\beta$ be the angular difference between target and radar as the radar resumes scan of the sector after a confirmation assignment. Figure 3 then applies.

\[ \alpha \quad \beta \]
\[ 0^\circ \quad 50^\circ \]

Target \quad \text{Radar}

\[ \text{Scan interval} = B^\circ \]

\[ \alpha \]

Figure 3. Scan Interval

**Case 1.** As radar resumes surveillance scan from position $\alpha$ (random variable), let it be in motion toward the target. Then the time for two scans, assuming the target is stationary in azimuth, would be

\[ T_{D_1} = \frac{\alpha}{V_S} + \frac{\alpha - \beta}{V_S} + \frac{2V_S}{a} \]

where $2V_S/a = \text{time period to turn around at end of scan position.}$
Case 2. As radar resumes surveillance from position $\alpha$, let it be in motion away from the target. Then the time for two scans would be

$$T_{D_2} = \frac{B^0 - \alpha}{V_S} + \frac{2V_S}{a} + \frac{B^0}{V_S} + \frac{2V_S}{a} + \frac{\alpha - \beta}{V_S}.$$ 

Case 3. In the foregoing, we assumed that $\beta$ was such that the target was to the left of the tracker at resumption of scan. If we assume that the target is to the right of the radar, again with angular difference $\beta$, then with the radar moving toward the target we obtain:

$$T_{D_3} = \frac{2B^0}{V_S} - \frac{2\alpha}{V_S} - \frac{\beta}{V_S} + \frac{2V_S}{a}.$$

Case 4. With the radar moving away from the target we obtain

$$T_{D_4} = \frac{2B^0}{V_S} - \frac{\beta}{V_S} + \frac{3V_S}{a}.$$

If we assign a probability weight of 1/4 to each case (i.e., it is equally probable that, given $\beta$ to the left or right of the radar, the radar moves toward or away from target as it resumes scan), then

$$\frac{1}{4} \left[ T_{D_1} + T_{D_2} + T_{D_3} + T_{D_4} \right] = \frac{3B^0}{2V_S} - \frac{\beta}{V_S} + \frac{3V_S}{a}.$$
It is important to note, at this point, that the starting position of the radar, $\alpha$, has vanished from the computation. However, the random variable, $\beta$, has not vanished, and we replace it by its average value,

$$E(\beta) = 0$$

to produce our final result:

$$T_D = \frac{3B^o}{2V_S} - \frac{E(\beta)}{V_S} + \frac{3V_S}{a}$$

$$= \frac{3B^o}{2V_S} + \frac{3V_S}{a},$$

which is used in the text.
An Efficiency Function for Rating Mechanical Scan-Track Radars

A function, \( P_d \), introduced in ESD-TDR-63-292, is derived as a measure of effectiveness in rating certain mechanical scan-track radar configurations in the joint performance two operational requirements. These are:

1. confirmation, i.e., acquisition and tracking of objects (missiles and/or satellites) detected by collocated surveillance radars, and
2. scanning, i.e., providing additional surveillance coverage for a missile threat in a sector not searched by the collocated surveillance radars.

We are mainly interested in the application of the \( P_d \) function to the problems of selecting a radar for BMESWS Site II service. It is thought, however, that the function would be of general interest to others with similar problems of selection under joint operating constraints.

### INSTRUCTIONS

1. **ORIGINATING ACTIVITY:** Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.

2a. **REPORT SECURITY CLASSIFICATION:** Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.

2b. **GROUP:** Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.

3. **REPORT TITLE:** Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.

4. **DESCRIPTIVE NOTES:** If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.

5. **AUTHOR(S):** Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.

6. **REPORT DATE:** Enter the date of the report as day, month, year; or month, year. If more than one date appears on the report, use date of publication.

7a. **TOTAL NUMBER OF PAGES:** The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.

7b. **NUMBER OF REFERENCES:** Enter the total number of references cited in the report.

8a. **CONTRACT OR GRANT NUMBER:** If appropriate, enter the applicable number of the contract or grant under which the report was written.

8b, 8c, & 8d. **PROJECT NUMBER:** Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.

9a. **ORIGINATOR'S REPORT NUMBER(S):** Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.

9b. **OTHER REPORT NUMBER(S):** If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter this number(s).

10. **AVAILABILITY/LIMITATION NOTICES:** Enter any limitations on further dissemination of the report, other than those imposed by security classification, using standard statements such as:

   1. "Qualified requesters may obtain copies of this report from DDC."
   2. "Foreign announcement and dissemination of this report by DDC is not authorized."
   3. "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through..."
   4. "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through..."
   5. "All distribution of this report is controlled. Qualified DDC users shall request through..."

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

11. **SUPPLEMENTARY NOTES:** Use for additional explanatory notes.

12. **SPONSORING MILITARY ACTIVITY:** Enter the name of the departmental project office or laboratory sponsoring (paying for) the research and development. Include address.

13. **ABSTRACT:** Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U).

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. **KEY WORDS:** Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, rules, and weights is optional.
