Captain C. W. Shilling (LC) U. S. N.
Medical Officer in Charge
Medical Research Laboratory
U. S. Submarine Base
New London, Conn.

August 9, 1944
COMPARISON OF RESULTS OBTAINED ON THE EXPERIMENTAL
FORM X-1 OF THE OFFICER MECHANICAL ATTITUDE TEST,
FORM X-1 (NAVPEARS-16640) WITH (1) RESULTS ON THE
OFFICER QUALIFICATION TEST, FORM 3, (NAVPEARS-
16563) AND (2) GRADES IN SUBMARINE SCHOOL.

Summary:

Means and standard deviations of test scores are reported for a
population of commissioned candidates for submarine school. Correla-
tion coefficients showing the relationship of the scores to each other
and to submarine school grades are presented. It is noted that of the
various sections of these tests, those on arithmetic reasoning and
mechanical comprehension yield the largest coefficients.

At the present time the officers' course in the submarine school
involves 12 weeks of study in the principles and operation of subma-
rines. All candidates for the school are volunteers, and are assigned
to New London only after approval of their qualifications. Indeed,
those who are assigned from Midshipmen schools have been carefully
screened by a board of submarine officers prior to assignment. Thus
the population on which this report is based is a somewhat selected
sample of junior commissioned officers.

The study was undertaken in order to determine the interrelation-
ship of certain selection devices and the success of those devices in
predicting grades in submarine school. The choice of tests was govern-
ed by previous decisions on the proposed content of the Officer Classi-
fication Test; both scales discussed in this paper are incorporated in
modified form in this new instrument.

OSRD Report No. 3163 indicates that one of the three sections of
the Officer Qualification Test bears a low relationship to grades in
indoctrination school. The weak section was that dealing with mechanical
comprehension. Preliminary research at this activity, however, made it
appear that the least valid of the three in terms of submarine school
grades was the vocabulary section. This study will furnish further data
on the question.

Procedure:

Both tests were applied as a part of the admission procedure for
candidates for submarine school. On the printed schedule for each
officer, one event was listed as "Aptitude Tests." Thus, although the

tests were actually experimental, the candidates regarded them as one

of the several hurdles which were to be satisfied along with the medi-
cal examinations, training in the use of the escape appliance, swimming
tests, etc. Since each officer was a volunteer for submarine duty,
conditions were ideal from the standpoint of test motivation. Physical
conditions for conducting examinations were also satisfactory. Altogeth-
er, four groups comprising a total of 284 officers were examined.

The order of administration was not varied. The Officer Qualifi-
cation Test was first on the schedule, then a ten-minute rest was inter-
polated before administration of the Mechanical Aptitude Test. There
were no pauses between sections of the latter beyond the time necessary
for the examiner to read the instructions aloud.

Only three sections of the Mechanical Aptitude Test were used;
Section A, dealing with assembly of plane surface figures, was omitted
in accordance with suggestions from the Test Research Unit of the
Bureau of Personnel. The time limits for the different sections are
as follows:

- Block Assembly: 15 minutes
- Rotation of Solid Figures: 20 minutes
- Mechanical Comprehension: 25 minutes

Some of the candidates failed to qualify for submarine school, and
others later failed the school because of low aptitude ratings. Neither
of these two groups is treated in this study, however. In the first
place, the failures are primarily a matter of evaluations of personal
aptitude rather than of academic grades. And second, test scores were
known to medical officers who figure to some extent in disqualifications.
Accordingly, it was decided to deal only with grades for officers who
completed the course.

Results:

Each test was scored by counting the number of questions answered
correctly. The correlation between total score for the three sections
of the CMAT and total raw score for the OCT is based on the entire
number tested, or 284. The product moment coefficient is 0.46. Means
and standard deviations for total scores and part scores for each test
are indicated in Table I, below.

Final grades in the submarine school are a weighted combination of several marks. Each examination grade is multiplied by a given coefficient, and the final grade is a fraction of the sum of the products. The coefficients in effect at this time are shown in Table II. It should be emphasized that the coefficients do not of themselves determine the weight of a given examination, because the variabilities for the examination grades differ. For example, the mean of the ranges for the three aptitude grades is approximately one-half the mean of the ranges for all other grades. The distributions and the intercorrelations of the grades are not discussed in this report, nor are correlations of tests with individual subjects treated. For the purposes of this study, the final multiple grade is assumed as the criterion.

**Discussion:**

Inspection of Table III shows that those sections involving arithmetic reasoning and mechanical comprehension are the most closely related to grades in submarine school. Indeed, the score on the arithmetic reasoning section alone appears to be as good an indicator of subsequent grades as the total OQT score, and the mechanical comprehension score of the CMAT is almost as efficient as the total CMAT score.
It is noted that a combination of the total scores for the GMAT and OQT tests does not increase the accuracy of the forecasting that can be made from the OQT alone. Of the combinations investigated, the sum of scores for the arithmetic reasoning and mechanical comprehension sections appears to be the most promising. However, no methods of combinations other than simple additions of raw scores have been explored. It has been suggested by various interviewing officers that some profile or grid scoring technique might yield better prediction than total scores. It is probable that such techniques involve low reliabilities, but at any rate these suggestions might be pursued in studies of the Officer Classification Test.

Analysis of the grades at the Submarine School is indicated before any elaborate studies of test validation may be executed. Arrangements for such research are underway, and should permit a detailed study of the Officer Classification Test in the near future. However, even without statistical analysis, one general characteristic of the final grade may be perceived by reference to Table II. This table points to a predominance of technical engineering material in the course.

Finally, it should be emphasized that no data were immediately available from previous administrations of officer selection instruments. A few individuals involved in this study volunteered the information that they had been examined twice with other forms of the Officer Qualification Test. There are no means of evaluating the influence of antecedent tests on the scores reported herein. At any rate, there would have been a saving in testing time and possibly some change in score distributions and validity coefficients if records for previous examinations had been maintained in such form that they were accessible.
