ABSTRACT

The definitions of scheduling relations previously presented by the author are extended in this report to allow the translation of a relation net into an exact schedule. Time conditional conflicts in scheduling relation nets are detected and resolved by operating on extended versions of the bilateral implication and truth tables.

REVIEW AND APPROVAL

This technical report has been reviewed and is approved.

SECTION I

INTRODUCTION

The analysis of logical scheduling conflicts was formulated in (Ref. 1). Some of the relations defined (see Section 3.1 of Ref. 1), such as $K$, $Y$, and $\Phi$, exactly fix the time lines of pairs of activities with respect to one another. A scheduling relation having this property is metrized. The relations $\Gamma$, $\Sigma$, and $N$, for example, do not have this property and are therefore unmetrized. The process of extending the definition of an unmetrized relation so that the newly defined relation is metrized will be called metrization. The metrization of the relations defined in (Ref. 1) will be undertaken in Section II. In the same section, we shall show that an exact schedule ¹ can be produced from a relation net providing that (a) the relations of the net are metrized, (b) the duration of each activity in the net is known, and (c) the start or finish time of any of the activities is known.

In Section II we answer the question: Given the implication of a relative product of scheduling relations, what is the metrized implication of the corresponding product of metrized relations? The reader will recall that in (Ref. 1) a bilateral implication table was used to derive the relation between any two activities of a relation net. Given the same activities, along with their respective lengths, we now wish to quantitatively express the relationship between the activities in terms of the metrized relations of the relative strings to which the activities belong. It will be shown in Section II that a metrized version of the bilateral implication table of (Ref. 1) is sufficient for this task.

¹) A schedule in which the start and finish times of each activity are fixed relative to a time line.
The truth values of cyclic relative strings were used as a basis for logical conflict detection in (Ref. 1). In Section II, we will use true cyclic strings of metrized relations to derive a basic set of conditional equations. These equations will be put to use in the detection and resolution of time conditional conflicts in Section III.

Other applications of metrized scheduling relations include the prediction of conflicts due to the delay or slipping of activity start and finish times, the extension of relation nets in a conflict-free manner (a capability crucially needed for the inter-relating of two or more profiles), and the study of the properties of alternative schedules generated by relation nets containing very general constraints such as $\Omega, \Omega', \Omega^\dagger$, and $\Delta^1$. All of these applications will be discussed in depth in this report.

---

1) There are, for example, four forms of $\Omega'$, including $\Gamma$, $\Gamma^\dagger$, $K$, and $K$. A relation net containing $\Omega$ will, therefore, generate at least four schedules.
SECTION II
METRIZED SCHEDULING RELATIONS

DEFINITION OF METRIZED SCHEDULING RELATIONS

The reader is assumed to be familiar with the algebraic definitions of the scheduling relations given in (Ref. 1). As observed in the introduction, certain of these relations are already metrized. Thus given the durations of activities $X$ and $Y$, and the start or finish time of either $X$ or $Y$, exact schedules can be produced from $XKY$, $XKY$, $XYY$, $XAY$, and $XYY$. We now extend the definitions of the remaining relations so that under the same conditions it is possible to produce exact schedules from any string of the form $XuY$. Definitions of the metrized relations are presented in Appendix I. To produce an exact schedule of $XuY$, for example, requires not only knowledge about the relates $X$ and $Y$ (durations and start or finish times), but also more knowledge about $\Gamma$ than is contained in its purely algebraic definition. The additional parameter $i = A(\ast Y) - A(\ast X)$ is easily seen to be the needed parameter. The metrization of $\Sigma$, on the other hand, requires the introduction of two parameters, $i = A(\ast X) - A(\ast Y)$ and $j = A(\ast Y) - A(\ast X)$. Each definition or Appendix I is accompanied by a figure which is an example of the position of the relates as governed by the defined relation.

The relations $\Omega$, $\Omega'$, and $\Delta$ (Definitions 18, 19, and 20 of Appendix I) require special mention, since their metrized forms can be
expressed only as functions of previously defined relations. Observe that there are several ways of writing the metrized versions of both \( \Omega \) and \( \Delta \). For example, \( X \delta Y \leftrightarrow X(\psi \vee \delta(i) \vee \tilde{\delta}(i))Y \) and \( X \delta Y \leftrightarrow X(\lambda \vee \theta(i) \vee \tilde{\theta}(i))Y \). In Definition 18, \( \Omega \) is expressed as the union of all of the relations contained in \( \Omega \). \(^1\) \( \Omega' \) (Def. 19) is easier to handle since it is the join of 4, and only 4, mutually exclusive relations. The employment of these relations, and of their equivalent modes of expression, will be treated in the following subsection and on page 7. For now, we note that the inclusion of one or more of the relations \( \Omega \), \( \Omega' \), or \( \Delta \) in a relation net gives rise to a combinatorial problem of some stature.

**DERIVATION OF METRIZED IMPLICATION TABLE**

Denoting the metrized form of a relation \( \omega \) by \( M(\omega) \), and given \( \delta \) as the implication of the relative product \( \omega_1 \omega_2 \), we now wish to derive \( M(\delta) \) as a function of \( M(\omega_1) \) and \( M(\omega_2) \). Briefly, our task is to compute the metrized implication of the relative product \( M(\omega_1) M(\omega_2) \).

We introduce these notions by way of examples. Let \( M(\omega_1) = \Gamma(i) \) and \( M(\omega_2) = \Gamma(j) \). From Appendix A of (Ref. 1) we have \( \Gamma \Gamma = \Gamma \). Thus \( X \Gamma(i)Y \Gamma(j)Z = X \Gamma(k)Z \) for some value of \( k \). From

---

\(^1\) Thus yielding a union of non-mutually exclusive relations. \( X \Sigma(i,j)Y \), for instance, implies \( X \theta(j)Y \) and hence \( \Sigma(i,j) \vee \theta(j) = \theta(j) \).
Figure 1 it is easy to see that \( X \Gamma(i + |Y| + j)Z \) and thus
\[ k = i + |Y| + j. \]
The metrized implication \( M(\delta) \) of \( \Gamma(i) \Gamma(j) \) is thus \( \Gamma(i + |Y| + j). \)

From Appendix I of (Ref. 1) we have \( \Gamma \Sigma = \check{P} \). To metrize the implication of \( M(\Gamma) M(\Sigma) \) we form the equation
\[ \Gamma(i) \Sigma(n,m) = \check{P}(k)^1 \]
and solve for \( k \). The solution is again easily seen from Figure 2, where, clearly, \( k = i + |Y| + m \). Thus \( \Gamma(i) \Sigma(n,m) = \check{P}(i + |Y| + m) \).

Appendix II of this paper is a complete table of metrized implications for binary products of the relations defined in Appendix A. The reader will observe that those implications containing more than one term are written out in conditional form, i.e., with restrictions as to when each form is used. As noted in the previous section, there are various ways of writing the metrization of both \( \Omega \) and \( \Delta \). The metrization of those products having implications containing \( \Omega \) and \( \Delta \) can thus take on several forms. In each of these cases we have, in Appendix B, used what appears to be the most easily deriveable form.
\[ \check{\check{R}}(n) \check{P}(m) \], for instance, equals \( \check{P}(m - (n + |X|)) \) or \( \Lambda \) (if

1) Where \( X, Y, \) and \( Z \) are understood to be, respectively, the first, middle, and last relates of the string.
m = n + |x| or P(n + |x| - m), (Ω ∨ Ω' = P ∨ Λ ∨ P since P includes Γ, Κ, Α, and Σ, Λ includes Ψ, P includes Γ, Κ, Α, and Σ, P ∨ Λ ∨ P ⇔ Ω ∨ Ψ ∨ N, and N includes Β, and N includes Β). T(n) P(m) also equals Ω(n - (m - |z|)) or Y (if m - |z| = n) or N(m - |z| - n), since, again, Ω ∨ Ω' = Ω ∨ Ψ ∨ N. Either one of the metrized implications of T(n) P(m) is thus equally acceptable, although we have included only the former in the implication table of Appendix II.

Metrized Version of Truth Table

The truth value of the cyclic ternary string Xω1 Yω2 X does not, of course, change when ω1 and ω2 are metrized. Cyclic strings in this section will thus always mean true cyclic strings. With the exception of the cycles ΚΚ, 1) ΨΨ, and ΛΛ, which, in their metrized form, carry neither new parameters nor information about the lengths of the relates, the significance of a ternary cycle of metrized relations is that it implies an equation holding among the parameters of the relations and the lengths of the relates. Hence, the '1' values in the truth table of Appendix II, (Ref. 1), can each (with the above noted exceptions) be replaced by an equation. Figures 3 and 4 exhibit the meaning of these equations for the cycles XΣ(i,j) Y ω(n)X and XΚY N(i)X, respectively.

1) Equivalently, ΚΚ
From Figure 3 we have \( i + ||X|| + n = ||Y|| \). From Figure 4 we have the simpler equation \( n = ||Y|| \). These equations, on the surface trivial, are given in Appendix III. Their enormous role in the detection and resolution of time-conditional conflicts will be seen in Section III.

METRIZED RELATION NETS

Given \( A(*X) \), \( ||X|| \), \( ||Y|| \), and \( XM(u)Y \), where \( M(u) \) is the metrization of the relation \( w \), it is easy to show that \( A(X*) \), \( A(*Y) \), and \( A(Y*) \) can be computed, i.e., an exact schedule of \( XuY \) can be produced. For example, if \( Xo(i)Y \), then, under the stated conditions, we have: \( A(X*) = A(*X) + ||X||, \ A(Y*) = A(X*) + i, \) and \( A(*Y) = A(Y*) - ||Y||. \) It readily follows that given a metrized relation net \(^1\), i.e., a relation net each of whose areas is metrized, and given \( ||X|| \) for each node of the net, then an exact schedule corresponding to the net can be produced providing we only know \( A(*X_t) \) for some \( X_t \).

Figure 5 shows a metrized relation net.

---

1) A net with truth value equal to 1, since it makes no sense to metrize nets containing logical conflicts.
Given $||x||$, $||y||$, $||z||$, $||v||$, $||w||$, and $A(*x)$, the schedule represented by the net is generated as follows:

1) $A(x*) = A(*x) + ||x||$

2) $A(*y) = A(x*) + 1$

3) $A(y*) = A(*y) + ||y||$

4) $A(*z) = A(*y)$

5) $A(z*) = A(*z) + ||z||$

6) $A(*v) = A(*z) - n$

7) $A(v*) = A(z*) + m$

8) $A(*w) = A(*v)$

9) $A(w*) = A(*x) \cdot j$

(observe that $||v||$ and $||w||$, although not used, could have been employed, respectively, in equations 7) and 9) in the calculations, respectively, of $A(v*) (= A(*v) + ||v||)$ and $A(w*) (= A(*w) + ||w||)$)

These calculations do, of course, flow directly from the definitions of $A(*)$

The schedule is shown in Figure 6

1) We have assumed that the durations and relation parameters are such that the relations of the net are satisfied, i.e., the net is not in conditional conflict (see Section III, page 21).
It is interesting to compute the metrized derived constraint between X and V. From X to V through Y we form the string $X \Xi(1)Y \Psi Z \Sigma(n,m)V$. From Appendix B we have $X \Xi(1)Y \Psi Z = X \Xi(1)Z$ and $X \Xi(1)Z \Sigma(n,m)V = X \tilde{\Pi}(i + m + ||Z||)V$, letting $n = i$, $i = n$, $j = m$, and $||Y|| = ||Z||$ in the table. From X to V through W we have $X \tilde{\Pi}(j)W \Psi V$, which, from Appendix II, reduces to $X \tilde{\Xi}(j + ||W||)V$. Now $\tilde{\Xi} \tilde{\Pi} = \Sigma$ and hence $X \Sigma(j + ||W||, i + m + ||Z||)V$, as seen in Figure 6.

In the initial stage of defining constraints it is sufficient, for certain activities, to express $X \Omega Y$, $X \Omega' Y$, or $X \Delta Y$ without specifying any ordering of X with respect to Y. There are, in fact, good reasons for employing these general relations whenever possible. The chief advantage, as will be seen from our next example (and also in our future work on the time-line packing of subschedules), is that the planner is provided with a variety of schedules for a given net, each possibly different in some critical operational aspect. It is true that the excessive use of such relations will induce combinatorial problems of great complexity. On the other hand, there is little excuse for reducing the number of solutions to a problem in the interests of achieving a simplicity and rigidity corresponding only to the most highly deterministic
(and therefore improbable) situations.

Figure 7 shows the set of schedules generated by the metrized relation net $\Sigma(i,j)Y$, $Y\Omega'Z$, $Z\alpha(S)W$, and $W\Delta T$, where $T$ denotes an interval of time with left hand endpoint at the beginning of the time line, i.e., $\ast T = \emptyset$ and hence $A(\ast T) = 0^1$. Cases 1, 2, 3, and 4 correspond, respectively, to $\Omega' = \Gamma(n)$, $\Omega' = K$, $\Omega' = \Gamma(n)$, and $\Omega' = K$. The total durations of the subschedules are $\|Y\| + n + \|Z\|$ + $S$ (Case 1), $\|Y\| + \|Z\| + S$ (Case 2), $\|Z\| + n + \|Y\|$ (Case 3), and $\|Z\| + \|Y\|$ (Case 4). If it is desired that either $X$ or $Y$ precede $Z$, then Cases 1 and 2 apply. If the shortest subschedule having either $X$ or $Y$ precede $Z$ is desired, then Case 2 alone applies. The shortest subschedule is obtained in Case 4.

Case 1. $\Omega' = \Gamma(n)$

Case 2. $\Omega' = K$

Case 3. $\Omega' = \Gamma(n)$

Case 4. $\Omega' = K$

1) The activity $T$ is used in defining constraints between physical activities and the schedule time line. (See Section III)
The choice of a subschedule may also be dictated by relations holding between nets which, as soon as we know what is meant by the left and right partial complements of a net, may be defined precisely as they are between activities.

For any net $n$ define $\ast n$ to be $\ast X_i$, $X_i \in n$, where $\ast X_i (N \forall j) X_j$ for each $X_i \in n$. Similarly, define $n^*$ to be $X_k^*$, $X_k \in n$, where $X_k^* (P \forall j) X_j^*$ for each $X_j \in n$. Finally, define $||n|| = A(n^*) - A(\ast n)$ to be the length of the net $n$. Figure 8 shows the situation for a net $n$ with seven activities.

![Diagram](Fig. 8)

Define $n_1$ to be net $X_{\Sigma \Omega Z_{\omega \Lambda} 1}$ and let $n_2$ be the net $TKX'KY'KZ'$. Suppose it has been determined that $n_1 \Omega n_2$ must hold. From a Gantt chart construction it is then immediately evident that $n_1 \cap n_2$. We will now derive this constraint directly. Since the activity $W$ is a part of $n_1$ we can write $n_1 \cap \bar{W}$. Figure 9 is the relation net of the composition of $n_1$ and $n_2$.

1) $T$ as in Figure 7.
From the implication table of (Ref. 1) we have \( n_1(\Sigma \Lambda K)n_2 = n_1(\Lambda \lor \tilde{\alpha})Kn_2 \)
\( = n_1(K \lor \tilde{\sigma}n_2). \) Now \( \Omega' = K \lor \tilde{\sigma} \lor \tilde{\beta} \lor \tilde{\gamma}. \) Hence \( n_1(K \lor \tilde{\sigma})\Omega'n_1 \)
\( = n_1(K \lor \tilde{\sigma})(K \lor \tilde{\sigma} \lor \tilde{\beta} \lor \tilde{\gamma})n_1 = n_1(KK \lor K \lor K \lor K) \lor \tilde{\beta} \lor \tilde{\gamma} \lor \tilde{\delta} \lor \tilde{\epsilon})n_1. \) From
the truth table of (Ref. 1) we find that all of these cyclic ternary strings are false with the exception of \( \tilde{\alpha} \). Hence \( \Omega' = K \) and
\( n_1Kn_2 \tilde{\alpha}n_1, \) i.e. \( n_2K_n, \) as we set out to prove.

It is now clear that Cases 1 and 2 are the least likely to result in a violation of \( n_1Kn_2 \) (\( ||*Z|| + ||Z|| + n + ||Y|| \) may exceed \( ||T||, \) for example, in Case 3). We shall return to this example in Section III, where we will use metrized relations to deduce directly the desirability of Cases 1 and 2. At this point it is important to see the way in which relations between nets reduce the combinatorial problems generated by relations such as \( \Omega \) and \( \Omega' \) within nets.
SECTION III
CONDITIONAL CONFLICTS

BASIC FORMS FOR THE GENERATION OF CONDITIONAL EQUATIONS

Scheduling conflicts arising from logical incompatibilities among scheduling constraints were discussed in (Ref. 1). It will be recalled that a Gantt chart of a relation net exists if and only if the truth value of the net is 1. Thus given a true relation net it is always possible to satisfy the net's relations by some set of activity durations. 1) Given the start time of any activity, a Gantt chart of the net can then be produced. These statements hold true for metrized relation nets, as well, the only difference being that the set of Gantt charts corresponding to a metrized net is generally properly included in the set of Gantt charts corresponding to the unmetrized version of the same net, a consequence of the added restrictions imposed by the parameters of the metrized relations.

A metrized relation net is **realizable** if the durations of the activities, along with the start or finish time of some activity, are given. From Section II, page 7, it follows that the start and finish times of each activity of a realizable net are determined. Define the **metric variables**, or $m$-variables, of a realizable net $n$ to be the collection $M(n)$ of durations and start times of the net's activities, along with

---

1) The cardinality of the class of such sets is, in general, $2^\infty$.  

13
the parameters of the net's relations. A realizable net is in \textit{conditional conflict} if any of the members of $M(n)$ undergo a change of value. We recognize four types of conditional conflict:

\textbf{Type I:} The $m$-variable changes leave each of the relations of the net fixed.

\textbf{Type II:} The $m$-variable changes induce a change of the relations of the net, but a redefinition of the $m$-variables restores the original relations.

\textbf{Type III:} The $m$-variable changes induce a change of the relations of the net, no restoration of the original relations is possible by redefining the $m$-variables, but the new net is not in logical conflict.

\textbf{Type IV:} Identical to Case 3 except that the new net is in logical conflict.

In this paper, we shall fully treat Types I and II, and give some analytical insight into Types III and IV.\(^1\)

We now turn to the application of metrized relation nets to exact scheduling. The basic principles of application can be deduced from nets having only one activity that must be completed at a specified time, and we so restrict our discussion in this section. The general case, in which several activities of a net are constrained to the time line, will be treated in Section III, page 21.

\(^1\) Types III and IV will be treated in general in "Heuristics for the Resolution of Logical and Conditional Scheduling Conflicts" by L. C. Driscoll, The MITRE Corporation. MTR-110 (To be published)
The example in Figure 7 of the previous subsection will serve as the starting point of our development of a set of equations from a realizable net. We begin with Case 1, in which \( \Omega' = \Gamma(n) \). Define \( dX, dY, dZ, \) and \( dW \), respectively, as the durations of \( *X, *Y, *Z, \) and \( *W \). 1)

We then immediately have \( TN(dX)X, TN(dY)Y, TN(dZ)Z, \) and \( TN(dW)W \). Figure 10 is the metrized relation net for Case 1 with the above relations included.

![Diagram](Fig. 10)

From the metrized implication table of Appendix B, we find that \( X\Sigma(i, j, k)Y\Gamma(n)Z\alpha(s)W\Lambda T = X\Gamma(j + n)Z\alpha(s)W\Lambda T = XP(j + n + s + ||Z||)W\Lambda T = XP(j + n + s + ||Z||)T \). We now form the cyclic ternary string \( XP(j + n + s + ||Z||)TN(dX)X \) and, from the metrized truth table of Appendix III, find that this string is equivalent to \( j + n + s + ||Z|| + dX + ||X|| = ||T|| \), which is clearly seen in Figure 7. The metrized implication of \( Y\Gamma(n)Z\alpha(s)W\Lambda T \) is \( YP(n + s + ||Z||)T \). From the metrized truth table \( YP(n + s + ||Z||)TN(dY)Y \) is equivalent to

1) Note that \( dX \) is the start time of \( X \), etc.

15
n + s + |Z| + dY + |Y| = |T|, which is again evident in Figure 7. The equations dZ + |Z| + s = |T| and dW + |W| = |T| can be similarly derived.

The equations derived above are called partial conditional equations. Each has the property of being generated from a cycle of the form $X_0^0 X_1^1 \cdots X_n^n TN(dX_0)X_0$, involving both the activity $T$ (a section of the time line with $T = \emptyset$), and the start time of some other activity. A complete set of partial conditional equations of a realizable net is a set of partial conditional equations in which each $m$-variable of the net occurs in some equation of the set. The completion of the set of partial equations of the net of our example is obtained by substituting $i + |X| + j$ for $|Y|$ in any equation containing $|Y|$, since $X(i,j,Y)$ implies $i + |X| + j = |Y|$. A total conditional equation of a realizable net is the sum of any complete set of the net's partial conditional equations. A total equation of the net of our example is:

$$dX + dW + dZ + i + |Y| + |W| + 2(dY + |X| + j) + 3n + 4(s + |Z|) = 5|T|.$$  

It might be supposed that so long as this equation holds there can be no violation of the relations between the activities. A quick glance at Figure 7 will convince the reader that such is not the case. An increase in $n$, for example, cannot be offset by a decrease in $|W|$, since, from the partial equations, $|W|$ is not a function of $n$. One of the uses of total conditional equations will be seen on page 19. Obviously, the
relations in a realizable net will remain fixed so long as the partial equations hold and the relation parameters remain within their proper bounds.

Let \( n \) be a realizable net, \( T \) an activity of \( n \) with \( *T = \emptyset \), and \( Z \) an activity such that \( Z \not\subseteq T \) and \( *Z \neq \emptyset \). Then \( T \cap Z \).

For any activity \( X \) and relation \( \omega \) it is easy to verify that \( \zeta(X \cup Z \cap T \cap X) = 1 \). More explicitly, we have:

\[
\begin{align*}
\zeta(\Sigma A N) &= \zeta(\bar{P} N) \\
\zeta(\Xi A N) &= \zeta(A N) \\
\zeta(\Gamma A N) &= \zeta(P N) \\
\zeta(\iota A N) &= \zeta(\bar{T} N) \\
\zeta(K A N) &= \zeta(P N) \\
\zeta(K N) &= \zeta(K N) \\
\zeta(N A N) &= \zeta(A N) \lor \zeta(\Lambda N) \lor \zeta(\bar{P} N) \\
\zeta(N N) &= \zeta(P N) \lor \zeta(\Lambda N) \lor \zeta(\bar{P} N) \\
\zeta(P A N) &= \zeta(P N) \\
\zeta(P N) &= \zeta(P N) \\
\zeta(\bar{P} A N) &= \zeta(P N) \\
\zeta(\bar{P} N) &= \zeta(P N) \\
\zeta(\alpha A N) &= \zeta(P N) \\
\zeta(\rho A N) &= \zeta(P N) \\
\zeta(\sigma A N) &= \zeta(P N) \\
\zeta(\theta A N) &= \zeta(P N) \lor \zeta(\Lambda N) \lor \zeta(\bar{P} N) \\
\zeta(\phi A N) &= \zeta(P N) \lor \zeta(\Lambda N) \lor \zeta(\bar{P} N) \\
\zeta(\psi A N) &= \zeta(\bar{P} N) \lor \zeta(\psi N)(= 0) \lor \zeta(\bar{N})(= 0) \\
\zeta(\Lambda A N) &= \zeta(\Lambda N) \\
\zeta(\varphi A N) &= \zeta(\Lambda N)
\end{align*}
\]
Except where indicated, all truth values in the above list are equal to 1. The list can be decomposed into the following six classes:

- Class 1 - \( \tilde{P}N, aN \)
- Class 2 - \( PN, \tilde{a}N \)
- Class 3 - \( \tilde{T}N \)
- Class 4 - \( \tilde{K}N \)
- Class 5 - \( \Lambda N \)
- Class 6 - \( 8N \)

Letting \( n \) be the parameter of the first relation, and \( dx \) the parameter of the second \(^1\), these classes correspond (Appendix III), respectively, to the partial conditional equations:

1) \[ dX \pm ||X|| + n = ||T|| \]
2) \[ dX \pm ||X|| = ||T|| + n \]
3) \[ dX = n + ||T|| \]
4) \[ dX = ||T|| \]
5) \[ dX \pm ||X|| = ||T|| \]
6) \[ dX = n \]

It may appear that (6) does not involve \( ||T|| \), but \( 8N \) was the result of contracting \( X\PsiZATNX \). From the metrized implication table we find that \( X\PsiZAT = X8(||T|| - ||Z||)T \) and hence \( n = ||T|| - ||Z|| \) in (6).

The six classes of ternary cycles named above will be called the basic forms for the Generation of Conditional Equations.

\(^1\) Thus yielding the general form \( X\omega(n)TN(dx)X \)
RELATIONS BETWEEN NETS

In Section II, we presented an example of two nets, $n_1$, $n_2$, standing in the relation $n_1 \sim n_2$. $n_1$ contained the relation $\Omega'$, which gave rise to the four cases of Figure 7. It was stated that the desirability of Cases 1 and 2 could be deduced directly from a metrized relation net. A comparison of Cases 1 and 3 will illustrate the method.

The metrized derived constraint between $X$ and $T$ (Case 1) is $XP(j + n + s + ||Z||)T$. The metrized derived constraint between $X$ and $T$ (Case 3) takes not one, but three forms, depending on the magnitudes of the various $m$-variables involved. Thus

$$X\Sigma(i, j)Y\Gamma(n)Z\Omega(s)W\Lambda T$$ reduces to:

1. $XP(i + n - s + ||X||)T$ if $i + n + ||X|| > s$,
2. $X\Lambda T$ if $i + n + ||X|| = s$,
3. $XP(||X|| - i - n - s)T$ if $i + n + ||X|| < s$.

Turning now to Figure 9, we substitute $X$ for $W$ and, in succession, $P$, $\Lambda$, and $\bar{P}$ for $\Lambda$. The truth values of the resulting cycles are $\zeta(PK\bar{X}) = 0$, $\zeta(\Lambda X\bar{Z}) = 1$, and $\zeta(\bar{P}K\bar{X}) = 1$. Hence Case 3 can give rise to a logical conflict if $i + n + ||X|| > s$, whereas no such conflict is possible in Case 1. Comparisons of Case 1 with Case 4 and of Case 2 with Cases 3 and 4 will, naturally, yield similar results. This establishes the feasibility of automatically analyzing relations between nets without referring to Gantt charts.

The analysis of another problem involving relations between nets is based upon Figure 11, in which the realizable nets $n_1 = Y\Gamma(m)Z\Lambda T_1$ and $n_2 = U\Gamma(i)V\Gamma(j)W\Lambda T_2$ are related by $Y\Psi U$ and $Z\Omega'V$. Suppose we
let \( \Omega' \) be \( \Gamma(n) \), as in the figure.

The total conditional equation for the combination of \( n_1 \) and \( n_2 \) is
\[
\begin{align*}
|U| + i + dV + dW + 2(dY + dZ + dU + n) + 3(m + |Y|) \\
+ 4(|V| + j) + 5(|d| + |W|) = 3T_1 + 5T_2,
\end{align*}
\]
which yields
\[
n = \frac{1}{2}(5T_2 + 3T_1) - \left[\frac{1}{2}(|U| + i + dV + dW) + dY + dZ + dU + 3/2(m + |Y|) \\
+ 2(|V| + j) + 5/2(|Z| + |W|)\right].
\]
If \( n > 0 \) then \( \Gamma(n) \) is an acceptable form of \( \Omega' \). If \( n = 0 \) then \( \Omega' = K \). If \( n < 0 \) then \( \Omega' \) must take the form of either \( \tilde{\Omega}(n) \) or \( \tilde{K} \) and a new total conditional equation must be derived based upon \( V \) preceding \( Z \). Again, if \( n > 0 \) then \( \tilde{\Gamma}(n) \) is an acceptable form of \( \Omega' \). If \( n = 0 \) then \( \Omega' = K \). If \( n < 0 \) then either \( ZW \) must hold or some combination of the variables \( dY, |Y|, m, dU, \) etc. must be assigned new values. We thus see that introducing relations between realizable nets can induce conditional conflicts within the nets and, conversely, if the \( m \) - variables of several realizable nets are fixed, then the introduction of relations between the nets is not arbitrary, but must proceed within the limitations set by the total conditional equation of the related nets.
DETECTION AND RESOLUTION OF CONDITIONAL CONFLICTS

The partial conditional equations for Case 1, Figure 7, were derived on page 15. To increase the richness of the discussion which follows, we add the additional constraint $Y \Gamma(m) W$, thus introducing three more cycles into the net of Figure 10. The partial conditional equations for the augmented net are:

\[
\begin{align*}
    a) & \quad dY + |Y| + n + |Z| + s = |T| \\
    b) & \quad dY + i + |X| + j + n + |Z| + s = |T| \\
    c) & \quad dX + |X| + j + n + |Z| + s = |T| \\
    d) & \quad dZ + |Z| + s = |T| \\
    e) & \quad dW + |W| = |T| \\
    f) & \quad dY + |Y| + m + |W| = |T| \\
    g) & \quad dX + |X| + j + m + |W| = |T| \\
    h) & \quad dY + i + |X| + j + m + |W| = |T| 
\end{align*}
\]

Equations a) - e) were derived on page 15. f) - g) are a consequence of the added constraint $Y \Gamma(m) W$.

In this subsection, we shall explore the interdependence of $m$-variables in a metrized net and examine the ways in which changes in the $m$-variables propagate through the partial conditional equations. As stated previously, we shall confine ourselves to conditional conflicts of Types I and II.

This restriction is equivalent to the assumption that the matrix of coefficients (0's and 1's) of the linear system a) - h) is independent of $m$-variable changes.
To each $m$-variable $V$, except $||T||$, of the system $\text{a) } \rightarrow \text{h) }$, we now add the quantity $\hat{V}$, representing the change in $V$.

Subtraction of the system $\text{a) } \rightarrow \text{h) }$ from the new system yields a linear homogeneous system whose coefficient matrix is:

$$M = \begin{pmatrix}
\hat{d}Y & \hat{d}X & |X| & |\hat{Y}| & \hat{i} & \hat{j} & \hat{n} & \hat{m} & \hat{d}Z & \hat{d}W & |\hat{Z}| & |\hat{W}| & \hat{s} \\
1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 1 & a \\
1 & 0 & 1 & 0 & 1 & 1 & 0 & 0 & 0 & 1 & 0 & 1 & b \\
0 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 1 & 0 & c \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & d \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 & e \\
1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & f \\
0 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & g \\
1 & 0 & 1 & 0 & 1 & 1 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & h
\end{pmatrix}$$

$M$ represents a system of 8 equations and 13 unknowns. That $M$ has rank 6 is easily verified. From elementary algebra the nullity of $M$ is 7 and therefore the system has 7 linearly independent solutions forming a basis for the totality of solutions of the system.

The usual method for finding the basis for the null space of a matrix is to form the reduced echelon matrix by elementary row operations. The reduced echelon matrix of $M$ is:

$$22$$
The zero rows of $E_M$ indicate that the original equations a) - h) are linearly dependent. From $E_M$ we immediately conclude that

$$S = (-\hat{|Y|} - \hat{m} - \hat{|W|}, -\hat{|Y|} + \hat{i} - \hat{m} - \hat{|W|}, |\hat{Y|} - \hat{i} - \hat{j},$$

$$|\hat{Y|}, \hat{i}, \hat{j}, \hat{m} - |\hat{Z|} + |\hat{W|} - \hat{s}, \hat{m}, -|\hat{Z|} - \hat{s},$$

$$-|\hat{W|}, |\hat{Z|}, |\hat{W|}, |\hat{s|})$$

is the general solution of the system a) - h). Equivalently, we obtain all solutions by assigning arbitrary values to $|\hat{Y|}, \hat{i}, \hat{j}, \hat{m},$

$|\hat{Z|}, |\hat{W|},$ and $|\hat{s|},$ and solving the system

a) $\hat{dY} + |\hat{Y|} + \hat{m} + |\hat{W|} = 0$

b) $\hat{dX} + |\hat{Y|} - \hat{i} + \hat{m} + |\hat{W|} = 0$

c) $|\hat{X|} - |\hat{Y|} + \hat{i} + \hat{j} = 0$

d) $\hat{n} - \hat{m} + |\hat{Z|} - |\hat{W|} + \hat{s} = 0$

e) $\hat{dZ} + |\hat{Z|} + \hat{s} = 0$

f) $\hat{dW} + |\hat{W|} = 0$
for the remainder of the variables. In particular, the cases \( |\hat{|Y}| = 1, \)
\( i = j = m = |\hat{|Z}| = |\hat{|W}| = |\hat{|s}| = 0; \)
\( i = 1, |\hat{|Y}| = j = m = \ldots \)
\( = |\hat{|s}|; \) etc., provide a basis for the null space. Any linear combination
of basis vectors is, of course, a solution.

The basis vectors defined above allow us to develop resolutions
of conditional conflicts induced by m - variable changes within a metrized
relation net. For example, suppose in system a) - h) we allow the variable
m to decrease to m - 1\(^1\), i.e., \( m = -1. \) Since \( m \) is a basis variable
we set the remaining basis variables to 0, then solve the equations
\( a) \rightarrow f), \) obtaining \( \hat{d}Y = 1, \hat{d}X = 1, \hat{n} = -1, \) and \( |\hat{|X}| = \hat{d}Z = \hat{d}W = 0. \)

Figure 12 shows the effects of these changes (the new variables are primed).

The resolution above is by no means the most local, in the

\(^1\) 1 is assumed to be a small increment of time.
sense that the change in \( m \) induces changes in the least number of the remaining \( m \)-variables. A cursory inspection of the matrix \( M \) does, in fact, reveal that the local resolution to a decrease (or increase) in \( m \) is a corresponding decrease (increase) in \( dW \) and an increase (decrease) in \( W \). We shall presently develop an algorithm which will, in most cases, give local resolutions to conditional conflicts arising from \( m \)-variable changes.

From elementary algebra we know that a system of \( n \) homogeneous linear equations with \( n \) unknowns has nontrivial solutions if and only if the determinant of the system is 0. In particular, if the rank of the system is \( n \), then \( M \) has only the trivial solution, which signifies that either a Type III or Type IV conditional conflict has occurred (for example, some combination of the coefficients of the linear system \( a) \rightarrow h) \) has been changed; equivalently, one or more of the partial conditional equations of the net do not hold). If an \( m \)-variable \( V \) in a realizable net is not allowed to change, then \( \hat{V} = 0 \), and the properties of the linear homogeneous system corresponding to the \( m \)-variable changes are altered.

From the partial equations \( a) \rightarrow h) \) we construct a mapping \( F \) carrying each \( m \)-variable into the set of equations to which the variable belongs. We call \( F \) the \textit{m-variable association}, or simply the \textit{m.v.a.}, of the net. A few values of \( F \) are \( F(dZ) = \{d\} \), \( F(||Y||) = \{a, f\} \), and \( F(s) = \{a, b, c, d\} \). In (Ref. 2), it was shown that if \( B \) is a Boolean algebra of sets and \( a, b, \in B \), then the function

\[
\delta(a, b) = 1 - \frac{|a \cap b|}{|a \cup b|},
\]

where \(|a \cap b|\) and \(|a \cup b|\) are, respectively, the numbers of elements in
and $a \cup b$, is a pseudo-metric on $B$. We now apply this function to define the distances between $m$-variables of a metrized relation net. Thus if $X$ and $Y$ are $m$-variables of a net, then

$$
\delta(X, Y) = 1 - \frac{|F(X) \cap F(Y)|}{|F(X) \cup F(Y)|},
$$

where $F$ is the net's m.v.a. A few distances in the system $a) \rightarrow h)$ are:

$$
\delta(dZ, dW) = 1 - \frac{|\{d\} \cap \{e\}|}{|\{d, e\}|} = 1,
$$

$$
\delta(n, j) = 1 - \frac{|\{a, b, c\} \cap \{b, c, g, h\}|}{|\{a, b, c, g, h\}|} = 1 - 2/5 = .6,
$$

$$
\delta(s, ||Z||) = 1 - \frac{|\{a, b, c, d\} \cap \{a, b, c\}|}{|\{a, b, c, d\}|} = 1 - 1/1 = 0.
$$

The last case shows why $\delta$ is a pseudo-metric rather than a metric.

The matrix $M$ is the representation of the m.v.a. of the net from which the system $a) \rightarrow h)$ was derived. Using $\delta$, we now construct the local resolution to a change in $m$. Computing the distances between $m$ and the other $m$-variables we find that $||W||$ is the closest variable to $m$. We next define the quasi-$m$-variable $m/||W||$ by

$$
F(m/||W||) = (F(m) \cup F(||W||)) \cap [F(m) \cap F(||W||)],
$$

the symmetric difference between $F(m)$ and $F(||W||)$. The $m$-variable closest to $m/||W||$ is $d_Z$ and is fact $\delta(dW, m/||W||) = 0$. The computation ends here and it is evident that an increase (decrease) in $m$ can be accompanied by an equivalent decrease (increase) in $||W||$, which will in turn induce an equal increase (decrease) in $dW$. Observe that this resolution, although local, is an equal increment resolution, and not necessarily the most desirable. The existence of a non-trivial resolution still depends, of
of course, on the rank and structure of $M$, and the formation of $E_M$ still yields the most general resolutions.

We now extend the above process of conditional conflict resolution to nets containing two or more activities, each of which must be completed at a specified time. The method will be adequately demonstrated through Figures 13a) and 13b) which show, respectively, a metrized relation net and its corresponding schedule. Activities $Z$ and $R$ finish, respectively, at times $T_1$ and $T_2$.

![Diagram](image)

There are several ways of generating the partial conditional equations from the net of Figure 13a). We may, for example, generate the equations first with respect to the cycles containing $T_1$, and then with respect to the cycles containing $T_2$, the remaining equations coming from $X\Sigma(i,j)Y$ and $s\Sigma(U,V)R$, yielding, respectively, $i + ||X|| + j = ||Y||$ and $U + ||S|| + V = ||R||$. On the other hand we observe that $||T_1|| \leq ||T_2|| \Rightarrow T_2 \varphi(||T_2|| - ||T_1||)T_1$, the derived constraint
between \( T_2 \) and \( T_1 \). Figure 14 shows an alternative form of the net of Figure 13a).

We may now generate the partial conditional equations with respect to the cycles containing both \( T_2 \) and \( T_1 \) (through \( N(dX) \), \( N(dY) \), \( N(dZ) \)). Finally we may generate first with respect to cycles containing only \( T_1 \) (through \( N(dX) \), \( N(dY) \), \( N(dZ) \)) and then with respect to the cycles containing \( T_2 \) and \( T_1 \) (through \( N(dW) \), \( N(dS) \), \( N(dR) \)). The first method requires the least computation, but the symmetry of the second method is also attractive. The occurrence of a number of time-bound activities in a metrized relation net does not, at any rate, introduce any new problems in generating the partial conditional equations for the net.

We conclude this section with a discussion of dynamic conditional conflict detection and resolution (again restricting ourselves to Type I and Type II conflicts). The discussion will be based on the example used in the beginning of this section. Denote the start time of any activity,
or relation parameter, \( V \), by \( A(*)V \). In general the start times 
\( A(*)V_j \) of the activities and relation parameters \( V_j \) of a realizable net are partially ordered. In Case 1 of Figure 7 (with \( Yi(m)W \) added) we thus have 
\[ A(*)Y = A(*)i \leq A(*)X < A(*)j \leq A(*)n = A(*)m < A(*)Z \]
\[ \leq A(*)W < A(*)s < A(*)T, \] if we assume \( ||W|| \leq ||Z|| + s. \)

Suppose that the activities of the net are actually being performed. The first activity to start is \( Y \) and suppose, for the sake of argument, that \( Y \) is started late. From the \( m \)-variable change matrix \( M \) we form \( E_M \) and obtain a new set of values for some subset of the variables. It is now clear that the next change in the \( m \)-variables cannot involve \( \hat{d}Y \) and hence \( \hat{d}Y = 0 \). The column in \( M \), and hence \( E_M \), corresponding to \( \hat{d}Y \) is thus set to 0. Let \( M_1 \) and \( E_{M_1} \) be the new matrices thus formed. We infer that as the schedule is being completed we must form an ordered set of \( m \)-variable change matrices \( M_1 \), each having one less non-zero column than its predecessor. The ordering of the set of matrices exactly corresponds to the time ordering of the start and finish times of the net's activities. If at any time we encounter a \( n \times n \) matrix \( M_k \) with rank \( n \), then only the trivial solution obtains and either a Type III or Type IV conflict has been encountered. If no such matrix is encountered then the schedule can be realized with no change of relations, providing that only positive values of the \( m \)-variables are generated as solutions to conditional conflicts.

CONCLUSIONS

The detection and resolution of both logical and conditional conflicts in a complex plan, e.g. MOL, will most certainly require a partitioning of the plan into manageable sections, and thus induce partitions of the
schedules corresponding to that plan. Some of the problems of defining relations between subschedules have been briefly explored in this paper. In a subsequent paper we shall treat this subject in depth, with the aim of discovering rules for partitioning schedules, and of developing a full analysis of the problem of defining relations between subschedules.
APPENDIX I

METRIZED SCHEDULING RELATIONS

\(A(*X)\) and \(A(X*)\) are, respectively, the start and finish times of activity \(X\).

**Def. 1**

\[X(i)\gamma Y \iff A(X*) + i = A(*Y), \ i > 0\]

\[-X \rightarrow i \rightarrow Y \rightarrow \text{time}\]

**Def. 2**

\[X(i)\gamma Y \iff A(*X) = A(Y*) + i, \ i > 0\]

\[-Y \rightarrow i \rightarrow X \rightarrow \text{time}\]

Def. 20 \[ X \Delta Y \iff X(\psi \lor \theta(i) \lor \tilde{\theta}(i) \lor \land \lor \alpha(i) \lor \tilde{\alpha}(i) \lor \hat{\theta} \lor \Sigma(i,j) \lor \tilde{\Sigma}(i,j) \lor K \lor \tilde{K}) Y \]
APPENDIX II

METRIZED IMPLICATION TABLE

The metrized implications of ternary strings of the relations defined in Appendix I are given below. The general form is $Xw(i)Yw(j)Z = Xw_1(i_1)Z \lor Xw_2(i_2)Z \lor \ldots \lor Xw_n(i_n)Z$. The relates are not included in the table and $X$, $Y$, and $Z$ are always to be interpreted, respectively, as the initial, intermediate, and final relates of the string. To avoid long, cumbersome, expressions joins in implications are represented by commas, thus yielding lists of the elements of implications. The table is divided into relation classes, the first factor in each product being the relation class to which the product belongs. The products in each relation class correspond to a complete row of the bilateral implication table of (Ref. 1). The employment of the forms of $\Omega$, $\Omega'$, and $\Delta$ is explained in Section II, page 4.

APPENDIX III

METRIZED TRUTH TABLE

The following table corresponds to the truth table of (Ref. 1), with the exception that the entries for true ternary cycles are replaced by equations which must hold among the m - variables of the cycles. The general form of the cycle is taken as \( X \omega(i) \overline{Y \omega(j)} X \). As in the case of the metrized implication table relates are omitted. The relations \( \Omega, \Omega', \) and \( \Delta \) have not been included since the equations corresponding to true cycles containing those relations are already represented in the table (see pages 3 and 4). The table is symmetric and thus only half of it is shown. If one encounters a blank for \( X \omega(i) \overline{Y \omega(j)} X \), simply form \( X \overline{\omega(j)} Y \omega(i) X \) to find the corresponding equation.
### Metrized Truth Table

(X signifies that the cycle is true, but no equation exists for it)

**METRIZED SCHEDULING RELATIONS**

The definitions of scheduling relations previously presented by the author are extended in this report to allow the translation of a relation net into an exact schedule. Time conditional conflicts in scheduling relation nets are detected and resolved by operating on extended versions of the bilateral implication and truth tables.
1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.

2a. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate when "Restricted Data" is included. Rating is to be in accordance with appropriate security regulations.

2b. GROUP: Automatic downgrading is specified in DoD Directive 5200.16 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.

3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parentheses immediately following the title.

4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.

5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.

6. REPORT DATE: Enter the date of the report as day, month, year, or month, year, and month. If more than one date appears on the report, use date of publication.

7a. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.

7b. NUMBER OF REFERENCES: Enter the total number of references cited in the report.

8a. CONTRACT OR GRANT NUMBER: If appropriate, enter the number of the contract or grant under which the report was written.

8b, 8c, & 8d. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system number, task number, etc.

9a. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique in this report.

9b. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter this number(s).

10. AVAILABILITY LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those imposed by security considerations by using standard statements such as:

(1) "‘Qualified recipients may obtain copies of this report directly from DDC."

(2) "Foreign distribution and dissemination of this report is prevented by the sponsor."

(3) "U.S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through...

(4) "U.S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through...

(5) "All distribution of this report is controlled. Qualified DDC users shall request through...

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.

12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring (purchasing) the research and development. Include address.

13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, e.g., "unclassified" or "confidential." There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, rules, and weights is optional.

INSTRUCTIONS

1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.

2a. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Rating is to be in accordance with appropriate security regulations.

2b. GROUP: Automatic downgrading is specified in DoD Directive 5200.16 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.

3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parentheses immediately following the title.

4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.

5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.

6. REPORT DATE: Enter the date of the report as day, month, year, or month, year, and month. If more than one date appears on the report, use date of publication.

7a. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.

7b. NUMBER OF REFERENCES: Enter the total number of references cited in the report.

8a. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.

8b, 8c, & 8d. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system number, task number, etc.

9a. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique in this report.

9b. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter this number(s).

10. AVAILABILITY LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those imposed by security considerations by using standard statements such as:

(1) "Qualified recipients may obtain copies of this report from DDC."

(2) "Restricted Data" is included. Rating is to be in accordance with appropriate security regulations.
