DEVELOPMENT OF THE CONTINUOUS WIRE METHOD
PROGRESS REPORT IV. COMPARISON WITH OPTICAL MEASUREMENTS OF DETONATION PROPERTIES
Prepared by:
J. P. Toscano, A. R. Clairmont Jr., I. Jaffe, & D. Price

ABSTRACT: Measurements made with the continuous wire method are compared to those obtained optically of shock-to-detonation transitions in cast Comp B. The electronic and optical results are equivalent in detonation velocity measurements as they are for other explosives. For the transitional phenomena (e.g., delay time and run-length) the electronic method is much less precise than the optical. Hence the continuous wire method is not adequate for making such measurements in cast Comp B.

DEVELOPMENT OF THE CONTINUOUS WIRE METHOD PROGRESS REPORT IV.
COMPARISON WITH OPTICAL MEASUREMENTS OF DETONATION PROPERTIES

The work reported here was carried out under the task MAT 03L 000/
ROLL 01 01 Prob 059, Transition from Deflagration to Detonation.
This report is the fourth on the development work designed to make
the continuous wire method useful in studying the shock-to-detonation
transition of high explosives. Earlier work was reported in
NOLTRs 63-136, 66-21, and 67-10.

INTRODUCTION

This is the fourth report on application of the continuous wire method to studying shock-to-detonation transitions. This method uses three embedded wires which are parallel to the charge axis; two are copper and the third a Moleculoy resistance wire. The wires form two constant current circuits, the Cu-Cu and the Moleculoy-Cu, as diagrammed in the previous report. As a detonation reaction sweeps down the charge, the length and corresponding resistance of the Moleculoy wire remaining in the circuit decrease. In principle, the position of the detonation front as a function of time can be obtained from the oscilloscope record of resistance vs time.

The purpose of the present work was to compare continuous wire measurements with those obtained optically on the same charge. Cast Comp B was used throughout this study as a typical high explosive.

EXPERIMENTAL

All charges were of Comp B (60/40/1, RDX/TNT/Wax). They were cast, as previously described, about three wires held under tension in a cylindrical mold. A No. 32 Cu ground wire runs along the axis and is paralleled on either side by another Cu wire and by the Moleculoy resistance wire. The shot design, experimental procedure, and electronic circuitry were identical with those of the previous work. In addition, a 70 mm smear camera was used, at a writing speed of 4 mm/μsec, to follow the shock-to-detonation phenomena which appeared on the surface of the cylindrical charge. The camera slit was focused on the charge surface, parallel to the longitudinal axis, and viewed the entire length of the charge. An argon bomb was used to illuminate the initiating shock prior to detonation; the detonation could be followed by self luminosity.
After X-ray examination, the satisfactory charges were machined to 3.81 cm diam x 15.25 cm length. Charge density was 1.71-1.72 g/cc. The initiating shock was provided by two standard tetryl pellets (5.08 cm diam x 2.54 cm long, \( \rho_0 = 1.51 \) g/cc) followed by a gap of 0 to 37.4 mm of polymethyl methacrylate (PMMA) and cellulose acetate sheeting; the gap material also had a diameter of 5.08 cm. The calibration for this standard donor/gap system is given in Ref (3).

Fig. 1 shows typical electronic records for Shot 13. All electronic records were processed by the semi-automatic procedure fully described previously.2 Fig. 2 shows the smear camera record from the same charge (Smear Camera Record 297). The detonation velocity was obtained by fitting the x-t data to a hyperbolic function as described in Ref (4).

DISCUSSION OF RESULTS

Measurement of Detonation Velocity

The continuous wire method was originally designed to measure detonation velocity \( (D) \). Although this measurement is of only secondary interest in transitional studies, a comparison of the results from optical and electronic measurements is of value for other studies. Table 1 contains the velocity results from: (a) the Differential record, (b) the Moleculoy-Cu circuit record, and (c) the smear camera record. They are all essentially the same, although the differential records give results that are, on the average, 1% lower than the other two records. The maximum difference, which occurs only once, is 3%. We can conclude that the continuous wire method will give detonation velocity measurements in Comp B equivalent to those from optical methods.

Transitional Phenomena, Optical Records

The phenomena of interest in the shock-to-detonation transition are total delay time \( (\tau) \), run length \( (X_L) \), and time of chemical reaction prior to the onset of detonation. Of these, the smear camera records can give a measure of \( X_L \) and an estimate of \( \tau \). From other transitional studies, it is assumed that detonation is

* From Differential record.
** From Moleculoy-Cu record.
FIG. 1 ELECTRONIC RECORDS FOR SHOT 13 (GAP THICKNESS 145 CARDS)
initiated on the axis of the charge and then spreads in a hemispherical front. Hence the point of its break-out on the charge surface is at a distance \( X_t \) from the point of entry of the initiating shock. This point is located at the intersection of the trace of the predetonation shock and the detonation wave (See Fig. 2). From the \( X_t \) value and the writing speed of the camera, an approximate delay time \( \tau_a \) can be obtained. It is actually the predetonation time on the surface of the charge, but because of the curved surface of the initiating shock and the time required for detonation to spread from the charge axis to the charge surface, we cannot relate it exactly to the delay time on the axis of the charge.

The data \( X_t, \tau_a \) from the smear camera records are listed in Table 2 and plotted in Fig. 3. The curve \( \tau_a \) vs \( X_t \) is smooth, apparently linear, and extrapolates to \( \tau_a = -0.6 \) \( \mu \)sec at \( X_t = 0 \). This suggests that the true delay time is near \( (\tau_a + 0.6) \). Fig. 4 displays the data, initiating shock pressure \( P_e \) vs \( X_t \); again the curve is smooth and shows the trends established by other transitional studies. The log-log plots of \( P_e \) vs \( X_t \) and of excess delay time* vs \( X_t \) are linear as is the case with other good transitional data. In other words, the smear camera records provide precise and consistent \( X_t, \tau \) data.

The camera records do not, however, give any information about the time of predetonation reaction. Typically they show only a smoothly accelerating shock with most of the acceleration occurring just before detonation breaks out. In Fig. 2 the initial shock velocity is 3.00 mm/\( \mu \)sec and the velocity has reached 3.70 mm/\( \mu \)sec when the shock trace is obscured by the detonation break-out at \( X_t \).

**Transitional Phenomenon, Electronic Records**

In contrast to the optical records, the electronic ones do provide some information on the time of chemical reaction prior to the onset of detonation. Such transitional reactions would be

* Excess delay time is \( (\tau_a + 0.6) - X_tD^{-1} \)

** Time at which Cu record reaches zero volt line minus time at which Cu record first shows rise from imposed negative voltage (\(\sim -40\)V).
FIG. 3 $\tau_v$ VS $X_f$ FROM SMEAR CAMERA MEASUREMENTS IN CAST COMP B

FIG. 4 $P_e$ VS $X_f$ FROM SMEAR CAMERA MEASUREMENTS IN CAST COMP B
indicated by electrical conductance of their products and this con-
ductance should be measured by the Cu-Cu(ground) circuit. In the
case of DINA, the pre-detonation conductance could not be observed*; consequently it was possible to use the time at which this circuit
registered zero resistance as the moment at which detonation began.
For Comp B, the situation is very different. As the data of Table 2
show, at moderate initiating pressures, this interval was ~ 1.5 μsec,
and it increased to 11.5 μsec as the initiating pressure approached
its minimum value (50% point). DINA has a zero oxygen balance to
CO whereas Comp B has one of -10%. In thermal decomposition at the
hot spots, the products should not be very different, but the free
carbon from Comp B would probably increase the conductance of the
products above that to be expected from the DINA products (carbon
free). Although this factor may account for part of the difference
in this measurement, it does not seem likely to account for a 10-fold
difference in the duration of the transitional reactions. We suggest
that the major difference lies in the rate of growth to detonation
from burning in the ignition areas. This rate seems high for DINA
and relatively lower for Comp B. Of course, DINA requires that the
accelerated burning generate a pressure of only about 15 kbar whereas
Comp B requires about 38 kbar to achieve detonation. Even at the
same burning rate, Comp B would therefore require a longer time to
achieve detonation.

The Cu circuit records for shock-to-detonation transition in
DINA were sharp and easily read. They provided a time for the
onset of detonation which approximated the beginning of the straight
line portions of both the Differential and the Moleculoy records.
This is not the case for Comp B. Here the Cu record trace fre-
quently approaches the zero volt line asymptotically so that an end
point (beginning of detonation) is difficult to select. Moreover,

* If present, its duration was less than 0.5 μsec. In two charges,
an interval of about 1 μsec was observed.
the time so chosen does not seem to coincide with the beginning of detonation on the other two records. Consequently in the present work, the time of detonation onset was selected as that most consistent with all three records; a triple plot of voltage vs time was examined for each charge and particular weight was given to a time which appeared to be at the beginning of the straight line portion of both the Moleculoy and the Differential records. This procedure did not give satisfactory results for DINA, and, as will be shown, does not give acceptable results for Comp B either.

The values $X_t$ and $\tau$ obtained from the continuous wire records are also listed in Table 2, and plotted $\tau$ vs $X_t$ in Fig. 5. Here the scatter is so great that a straight line ending at the origin is used. Within the same large scatter, $P_e$ vs $X_t$ shows the usual trend (Fig. 6). But comparison of Figs. 3 and 4 with Figs. 5 and 6 readily shows the inadequacy of the electronic measurements. Although, as Fig. 7 shows, they are undoubtedly correlated with the optical results, they are too imprecise to be used for quantitative work. We conclude that the continuous wire method is inadequate for measuring $X_t$ and $\tau$ in shock-to-detonation transitions of Comp B.

Because the Moleculoy and Cu circuits are not independent, a few shots were made to compare the results from the Moleculoy records of charges containing two wires with those of the three wire charges. Some of these results are shown in Table 3. The two wire system appears to give larger values (ca. 0.5 $\mu$sec in $\tau$ and 5-8 mm in $X_t$), but these changes are no larger than errors that can be made in reading the records of a single shot or, indeed, of the maximum scatter of Fig. 5. It is not certain therefore whether the two wire system gives different results from those of the three wire system. Neither is satisfactory for measurements of transitional phenomena in Comp B.

CONCLUSIONS

The continuous wire method measures the detonation velocity of Comp B as precisely as does an optical method. It is, however, much too imprecise to measure run length or delay time in the shock-to-

Measurements made with the continuous wire method are compared to those obtained optically of shock-to-detonation transitions in cast Comp B. The electronic and optical results are equivalent in detonation velocity measurements as they are for other explosives. For the transitional phenomena (e.g., delay time and run-length) the electronic method is much less precise than the optical. Hence the continuous wire method is not adequate for making such measurements in cast Comp B.
Continuous Wire Measurements
Shock-to-Detonation Transition
Cast Comp B

INSTRUCTIONS

1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.

2a. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.

2b. GROUP: Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.

3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals immediately following the title.

4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.

5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.

6. REPORT DATE: Enter the date of the report as day, month, year; or month, year. If more than one date appears on the report, use date of publication.

7a. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.

7b. NUMBER OF REFERENCES: Enter the total number of references cited in the report.

8a. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.

8b, 8c, & 8d. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.

9a. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.

9b. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter this number(s).

10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those imposed by security classification, using standard statements such as:

(1) "Qualified requesters may obtain copies of this report from DDC."

(2) "Foreign announcement and dissemination of this report by DDC is not authorized."

(3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through ."

(4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through ."

(5) "All distribution of this report is controlled. Qualified DDC users shall request through ."

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.

12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring (paying for) the research and development. Include address.

13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U).

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, roles, and weights is optional.
Naval Ordnance Laboratory, White Oak, Md.

DEVELOPMENT OF THE CONTINUOUS WIRE METHOD. PROGRESS REPORT IV. COMPARISON WITH OPTICAL MEASUREMENTS OF DETONATION PROPERTIES, by J. F. Toscano and others. 2 April 1968. 15p. illus., charts, tables. ONR task MAT 03L 000/R011 01 01. UNCLASSIFIED

Measurements made with the continuous wire method are compared to those obtained optically of shock-to-detonation transitions in cast Comp B. The electronic and optical results are equivalent in detonation velocity measurements as they are for other explosives. For the transitional phenomena (e.g., delay time and run-length) the electronic method is much less precise than the optical. Hence the continuous wire method is not adequate for making such measurements in cast Comp B.
