THE HYPERSONIC LEADING EDGE PROBLEM
II. WEDGES AND CONES

Michael L. Shorenstein

April 1971

FLUID MECHANICS LABORATORY
An analysis is given for the viscous hypersonic flow past slender sharp wedges and unyawed cones. The leading edge or nose region treated encompasses the merged layer regime in which the shock thickness is not small in comparison with the viscous layer thickness but for which in the axisymmetric case the shock thickness is small in comparison with the radius of transverse shock curvature. A Navier-Stokes flow is assumed, and both the shock structure and viscous layer are taken to be locally-similar of boundary layer type. The analysis follows that used by Shorenstein and Probstein for the corresponding flat plate problem. For axisymmetric cone flow, a modification of a transformation introduced by Probstein and Elliott is given to reduce the axisymmetric viscous layer equations including transverse curvature to "exactly" two-dimensional form. Results for the state conditions behind the shock, and the wall pressure, skin friction, and heat transfer rate are found to be in good agreement with available experimental data.
1 ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.

2a. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.

2b. GROUP: Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.

3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.

4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.

5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter first name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.

6. REPORT DATE: Enter the date of the report as day, month, year; or month, year. If more than one date appears on the report, use date of publication.

7a. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.

7b. NUMBER OF REFERENCES: Enter the total number of references cited in the report.

8a. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.

8b. & 8d. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.

9. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.

9b. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter this number(s).

10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those imposed by security classification, using standard statements such as:

(1) "Qualified requesters may obtain copies of this report from DDC."

(2) "Foreign announcement and dissemination of this report by DDC is not authorized."

(3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through.

(4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through.

(5) "All distribution of this report is controlled. Qualified DDC users shall request through."

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.

12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring (paying for) the research and development. Include address.

13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U)

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, rules, and weights is optional.

THE HYPersonic LEADING EDGE PROBLEM

II. WEDGES AND CONES

by

Michael L. Shorenstein

Abstract

An analysis is given for the viscous hypersonic flow past slender sharp wedges and unyawed cones. The leading edge or nose region treated encompasses the merged layer regime in which the shock thickness is not small in comparison with the viscous layer thickness but for which in the axisymmetric case the shock thickness is small in comparison with the radius of transverse shock curvature. A Navier-Stokes flow is assumed, and both the shock structure and viscous layer are taken to be locally-similar of boundary layer type. The analysis follows that used by Shorenstein and Probstein for the corresponding flat plate problem. For axisymmetric cone flow, a modification of a transformation introduced by Probstein and Elliott is given to reduce the axisymmetric viscous layer equations including transverse curvature to "exactly" two-dimensional form. Results for the state conditions behind the shock, and the wall pressure, skin friction, and heat transfer rate are found to be in good agreement with available experimental data.

* The author wishes to thank sincerely Professor Ronald F. Probstein of M.I.T. for his support during the course of this investigation and for his valuable suggestions and criticisms. This research was supported by the Advanced Research Projects Agency and was technically administered by the Office of Naval Research under Contract No. N00014-0204-0040, ARPA Order No. 322.

Research Assistant, M.I.T., presently at Northern Research & Engineering Corp., Cambridge, Mass.
Nomenclature

A = velocity ratio, \( u_s^* / U_\infty \)
B = given by Eq. (18)
C = Chapman-Rubesin constant
\( C_1 \) = given by Eq. (20a)
\( C_2 \) = given by Eq. (20b)
c\( _F \) = skin friction coefficient
c\( _p \) = specific heat at constant pressure
D = reduced density, \( \rho / \rho_\infty \)
f = streamfunction given by Eq. (6)
\((f_{n})_b\) = reduced slip velocity, \( u_{s_b}^* / u_s^* \)
F = given by Eq. (43)
g = shear stress, \( Nf_{nn} \)
g(0) = value of \( g \) at body surface
h = specific enthalpy, \( c_p T \)
H = total enthalpy
I = given by Eq. (11)
j = index taken to be zero for two-dimensional flow and unity for axisymmetric flow
L = arbitrary fixed reference length
\( M_\infty \) = freestream Mach number
n = normal coordinate for shock structure
N = given by Eq. (5)
p = static pressure
P = reduced pressure, $p/p_\infty U_\infty^2$

Pr = Prandtl number

$Q_1(j)$ = given by Eq. (28)

$Q_2(j)$ = given by Eq. (29)

$Q_3(j)$ = given by Eq. (42)

r = radius of transverse curvature, $r_b + y^* \cos \theta_b$

R = gas constant

$Re_{\infty,*,x}$ = local Reynolds number, $\rho_\infty U_\infty x^*/u_\infty$

St = Stanton number

T = static temperature

$T_0$ = freestream stagnation temperature

$u, u^*$ = velocity component parallel to shock surface and to body surface, respectively [see Fig. 2]

$U_\infty$ = freestream velocity

$v, v^*$ = velocity component normal to shock surface and to body surface, respectively [see Fig. 2]

$\nabla$ = transformed normal velocity given by Eq. (2a)

$\nabla U$ = reduced velocity, $v/U_\infty$

$\nabla W$ = reduced velocity, $u/U_\infty$

$x^*, y^*$ = coordinate along body surface and normal to body surface, respectively [see Fig. 2]

$x, y$ = transformed coordinates given by Eq. (2a)

$\alpha$ = inverse Reynolds number $(\rho\infty U_\infty r_b/u_\infty)^{-1}$

$\gamma$ = specific heat ratio

$\Delta s$ = shock thickness

$\zeta$ = stretched normal coordinate for shock structure, Eq. (23)

$n$ = stretched normal coordinate for viscous layer, Eq. (6)
\( \eta_b \) = transformed location of the body surface for the case of slip
\( \eta_s \) = location of the shock surface
\( \theta_b \) = body surface inclination angle with respect to the free stream
\( \theta_s \) = shock surface inclination angle with respect to the body surface
\( H \) = reduced enthalpy given by Eq. (6)
\( \mu \) = viscosity
\( \mu \) = given by transformation Eq. (2b)
\( \zeta \) = transformed coordinate along body surface given by Eq. (6)
\( \rho \) = density
\( \sigma(j) \) = cross-section of streamtube incident to viscous layer
\( \phi \) = reduced enthalpy given by Eq. (23)
\( \gamma_{x*} \) = interaction parameter, \( N_{x*}^{1/2}(C/Re_{x*}) \)

**Subscripts**

\( b \) = condition at the body surface
\( ns \) = quantity obtained from no-slip solution
\( s \) = condition at the shock surface
\( st \) = quantity obtained from slip solution
\( \eta \) = derivative with respect to \( \eta \)
\( \infty \) = condition at the freestream
I. Introduction

Two classes of continuum flow models have been investigated recently for treating the hypersonic flow past sharp bodies upstream of the strong interaction regime in the merged layer [see Fig. 1] where the shock thickness must be considered finite in comparison with the viscous layer thickness. One class \(^{1-3}\) applies the full Navier-Stokes equations in finite difference form in order to determine to what extent a continuum may meaningfully describe the flow field in the merged layer. This complex scheme requires rather large computer storage space.

Another class of merged layer models \(^{4-6}\) uses the Navier-Stokes equations but assumes "local similarity" to apply in both the viscous layer and shock wave, that is, streamwise variations of all properties are taken to be sufficiently small, so that the Navier-Stokes equations, when applied locally, can be approximated by ordinary differential equations. This description of the merged viscous shock layer is obtained from locally-similar solutions "patched" at the interface between the outer shock structure portion and the inner viscous layer portion in which the equations are taken to be of boundary layer type with normal pressure gradient effects neglected. Results in Ref. 6 from such a merged layer model for a flat plate have compared well with experimental data \(^{7-9}\). The theoretical calculations have shown the relative importance of several rarefaction effects over a cold sharp flat plate aligned
parallel to the hypersonic freestream. Dominant among these effects was shown to be the finite shear at the interface between the back of the shock and the outer edge of the viscous layer. The effect of including velocity slip and temperature jump at the body surface was shown to be smaller but non-negligible, while the effect of including longitudinal shock curvature was found in comparison to be negligible.

The present analysis extends this flat plate continuum merged layer model of Ref. 6 to wedge and axisymmetric conical flows by investigating the additional effects of body slope and, for conical flow, the effects of axial symmetry and transverse curvature effects. Longitudinal shock curvature effects are neglected as small based on the results of Ref. 6. Body slope effects are characterized by the parameter $\theta_b$, where $\theta_b$ is the half angle of the wedge or unyawed cone. The analysis is extended only to slender bodies with $\theta_b \ll 1$ for which the normal component of the viscous layer velocity can be neglected compared to the tangential component. This restriction is introduced in order to solve the viscous layer problem by the method of Ref. 6.

In the axial symmetric case, a modification of a Mangier type transformation given by Probstein and Elliott\textsuperscript{10} is introduced to reduce the axisymmetric viscous layer equations to an "exactly" two-dimensional form. The modification involves a transformation applied to the viscosity coefficient, and this transformation is shown to include the effects of transverse curvature characterized by the
parameter $M_a$. Here $a$ is an inverse Reynolds number based on the body radius $r_b$ of transverse curvature, and $M_a$ is the freestream Mach number. A new term proportional to $M_a$ is found to modify the reduced viscous layer momentum equation of Ref. 6 and is shown to account for transverse curvature effects.

For the present investigation, two regimes of $M_a$ are distinguished: I, a regime immediately adjacent to the sharp nose where $M_a \gg 1$ and II, a regime downstream of the sharp nose where $M_a \ll 1$. Only the second regime is treated here. This restriction is introduced to obtain a simple closed form shock structure solution by a method analogous to Ref. 6. In the conical shock structure equations, transverse shock curvature terms are of order $\Lambda_s/r_s$ where $\Lambda_s$ is the shock thickness and $r_s$ is the radius of transverse shock curvature. It is found that if $M_a \ll 1$, then terms of order $\Lambda_s/r_s$ are negligible compared to the other terms in the shock structure equations. These equations can then be reduced to the form of the "zero-order" shock equations solved in Ref. 6.

II. Viscous Layer

As in Ref. 6, the merged shock layer is described by a viscous layer of boundary layer type patched at an outer interface (the "shock surface") to a thick shock structure. The velocity and state variables from the solution of the viscous layer equations are matched locally at the shock surface to the corresponding quantities from the solution of the shock structure equations.
The governing equations for the viscous layer written in the local body-centered coordinate frame \((x^*, y^*)\) depicted in Fig. 2 are

\[
\frac{\partial}{\partial x^*} \left( r^j \rho u^* \right) + \frac{\partial}{\partial y^*} \left( r^j \rho v^* \right) = 0
\]  

\( (1a) \)

\[
\rho \left( \frac{\partial u^*}{\partial x^*} + v^* \frac{\partial u^*}{\partial y^*} \right) = -\frac{\partial p}{\partial x^*} + \frac{\partial}{\partial y^*} \left( \mu \frac{\partial u^*}{\partial y^*} \right) + j \frac{\mu}{\rho} \frac{\partial}{\partial y^*} \frac{\partial u^*}{\partial y^*}
\]

\( (1b) \)

\[
\rho \left( \frac{\partial h^*}{\partial x^*} + v^* \frac{\partial h^*}{\partial y^*} \right) = u^* \frac{\partial p}{\partial x^*} + \frac{1}{\text{Pr}} \left( \frac{\partial}{\partial y^*} \left( \mu \frac{\partial h^*}{\partial y^*} \right) 
\right)
\]

\[
\quad + j \frac{\mu}{\rho} \frac{\partial}{\partial y^*} \frac{\partial h^*}{\partial y^*} + \mu \frac{\partial u^*}{\partial y^*}^2
\]

\( (1c) \)

where \( j = 0 \) for two-dimensional flow and \( j = 1 \) for axisymmetric flow, with \( r(x^*, y^*) = r_b(x^*) + y^* \cos \theta_b \) the local radius of transverse curvature for the case of axisymmetric flow with \( \theta_b \) the body slope relative to the freestream direction. The tangential and normal components of velocity are \( u^* \) and \( v^* \), respectively [see Fig. 2], \( h \) is the specific enthalpy, \( p \) is the pressure, \( \mu \) is the viscosity, and \( \text{Pr} \) is the Prandtl number taken to be a constant.

Probstein and Elliott\(^\text{10}\) introduced a generalized Mangler transformation which reduced Eqs. (1) to an almost two-dimensional form by applying the transformations

\[
\frac{dx}{L} = \left( \frac{r_b}{L} \right)^2 \frac{dx^*}{L} , \quad \frac{\partial}{\partial x^*} = \left( \frac{r_b}{L} \right)^2 \frac{\partial}{\partial x} + j \left( \frac{r_b}{L} \right)^2 \frac{\partial}{\partial y}
\]

\( (2a) \)

\[
\frac{dy}{L} = \left( \frac{r_b}{L} \right)^j \frac{dy^*}{L} , \quad \frac{\partial}{\partial y^*} = \left( \frac{r_b}{L} \right)^j \frac{\partial}{\partial y}
\]

\[
\frac{dv}{r_b} = \frac{1}{r_b} \left( \frac{L}{r_b} \right)^j v^* + j \left( \frac{L}{r_b} \right)^2 \frac{\partial}{\partial x^*} \frac{\partial u^*}{\partial y^*}
\]
where \( L \) is an arbitrary fixed reference length. By also introducing the transformation

\[
\bar{\mu} = (1 + \frac{2jL \bar{y} \cos \theta_b}{r_b^2}) \mu
\]  

(2b)

Eqs. (1) can be reduced "exactly" to two-dimensional form. This follows from the fact that \( \theta_b \) and \( r_b \) are functions of \( \bar{x} \) only, so that Eqs. (1) when transformed by means of Eqs. (2) give the homogeneous system

\[
\frac{\partial}{\partial \bar{x}} (\rho \bar{u}^*) + \frac{\partial}{\partial \bar{y}} (\rho \bar{v}) = 0
\]  

(3a)

\[
\rho (\bar{u}^* \frac{\partial \bar{u}^*}{\partial \bar{x}} + \bar{v} \frac{\partial \bar{u}^*}{\partial \bar{y}}) - \frac{\partial}{\partial \bar{y}} (\mu \frac{\partial \bar{u}^*}{\partial \bar{y}}) + \frac{\partial p}{\partial \bar{x}} = 0
\]  

(3b)

\[
\rho (\bar{u}^* \frac{\partial \bar{h}}{\partial \bar{x}} + \bar{v} \frac{\partial \bar{h}}{\partial \bar{y}}) - \frac{1}{Pr} \frac{\partial}{\partial \bar{y}} (\bar{u} \frac{\partial \bar{h}}{\partial \bar{y}}) - \bar{u} (\frac{\partial \bar{u}^*}{\partial \bar{y}})^2 - \bar{u}^* \frac{\partial p}{\partial \bar{x}} = 0
\]  

(3c)

which are "two-dimensional" in form. It must be pointed out, however, that the parameter \( \bar{\mu} \), although having the dimensions of a viscosity, is not a true state variable since it depends not only upon temperature but also on the geometry of the system. Still, Eqs. (3) can be interpreted as mathematically analogous to the equations of two-dimensional flow. Furthermore, Eqs. (3) can be solved by the method used in the viscous layer problem of Ref. 6 if \( \bar{v} \) can be taken as small compared to \( \bar{u}^* \). The present work
therefore extends the merged layer model of Ref. 6 only to slender bodies \((\theta_b << 1)\) for which the viscous layer streamline curvature \(\partial y^*/\partial x^*\) can be ignored and for which \(v^*\) is negligibly small compared to \(u^*\). For such bodies, by Eq. (2a), \(\bar{v} << u^*\).

With the governing equations in two-dimensional form and with \(\bar{v} << u^*\), the analysis can more directly parallel that of Ref. 6. Following this reference, the viscous layer adjacent to the body is assumed locally similar, and for a calorically perfect gas with a Prandtl number of unity, Eqs. (3b) and (3c) then reduce to

\[
\begin{align*}
(Nf^*)_{-ny} + f^*_{ny} &= 0 \\
(\bar{H})_n + f(\bar{H}) &= 0
\end{align*}
\]

where

\[
N = \rho u/\rho_b u_b
\]

and where the dimensionless independent and dependent variables are

\[
\begin{align*}
\eta &= \frac{u^*}{(2\zeta)^{1/2}} \int_0^y dy \\
\xi(x) &= \int_0^x \rho_b u_b u^* dx \\
f(\eta) &= \int_0^\eta \frac{u^*}{u^*_s} d\eta \\
\bar{H}(\eta) &= \frac{\bar{H} - \bar{H}_b}{\bar{H}_s - \bar{H}_b}
\end{align*}
\]

Here \(\bar{H}\) is the total enthalpy in the barred system (with \(\bar{v} << u^*\) and
the subscripts "s" and "b" denote quantities at the shock surface and body surface, respectively.

Following Ref. 6, we first consider the problem neglecting velocity slip and temperature jump at the body surface. With the body temperature $T_b$ constant, the boundary conditions are then

\[ f = f_s = 0 \quad \mathcal{H} = 0 \quad \text{at } \eta = 0 \]

\[ f = f_b = 1 \quad \mathcal{H} = 1 \quad \text{at } \eta = \eta_b \]

Consider now the energy equation (4b) which is satisfied by the Crocco integral $\mathcal{H} = f$. From the definition of total enthalpy (with $\bar{v} \ll \bar{u}^*$)

\[ \frac{T}{T_b} = (1 - f) \left[ 1 + A^2 \left( \frac{T}{T_b} \right)^2 f \right] \]

where

\[ A(x) = \frac{u^*}{U_m} \]

with $U_m$ the freestream velocity. For the hypersonic conditions considered, the freestream stagnation temperature $T_0$ is given by

\[ T_0 = \frac{U_m^2}{2c_p} \]

Consider next the viscous layer momentum equation (4a). An expression for $N$ is sought so that Eq. (4a) can be expressed in terms of the streamfunction $f(\eta)$ and its derivatives and in terms
of the local boundary conditions at the shock surface and the body. As shown in Pan and Probsteln⁴, the normal pressure gradient across the viscous layer is negligible when viscous layer streamline curvature is negligible. Thus, by $p = \rho RT$, $\rho_b/\rho = T/T_b$ so that from the definition of $\eta$ [Eq. (6)] it follows from Eq. (8) that at any given $x$

\[
\bar{y} = [(2\zeta)^{1/2}/\rho_b u^*] I(\eta) \tag{10}
\]

where

\[
I(\eta) = \int_0^\eta (1 - f_\eta) \left[ 1 + A^2(T_0/T_b) f_\eta \right] d\eta \tag{11}
\]

Hence, from Eq. (10) and from the definition of $\bar{u}$ [Eq. (2)]

\[
\bar{u}/u = 1 + B I(\eta) \tag{12}
\]

where $B$ is a function of the boundary conditions at $\eta = 0$ and $\eta = \eta_s$. Since $N = (\rho/\rho_b)(\bar{u}/u_b) = (T_b/T)(\bar{u}/u_b) = (T_b/T)(\bar{u}/u_b)/(\bar{u}/u)$ and if a viscosity-temperature relation of the form $\mu = T^{1/2}$ is assumed, then by Eq. (12)

\[
N = (T_b/T)^{1/2} \left[ 1 + B I(\eta) \right] \tag{13}
\]

To complete this expression for $N$, we now obtain $B$ in terms of the local boundary conditions at the shock surface and the body. This is done by first applying local conservation of mass flux
across the shock and into the viscous layer by use of

\[ \frac{y}{s} \rho \omega \omega \delta j = (2\pi L) \int_{0}^{1} \rho u^* \overline{d}y = (2\pi L) (2z)^{1/2} f(\eta_s) \]  

(14a)

where \( \delta j \) is the cross-section of the incident streamtube given by

\[ \delta j = \frac{1}{2} (\cot \theta_s - \tan \theta_r) \sin 2\theta_r \]  

(14b)

\[ \delta j = \pi r_s^2 \]  

(14c)

Now, from the definitions of \( \overline{x} \) [Eq. (2)] and of \( \xi(\overline{x}) \) [Eq. (6)], it can be shown that

\[ 2\xi = 2\rho u^* \delta j \left[ (1 - 2j/3) (r_b/L)^{2j} \right] x^* \]  

(15)

where \( r_b = x^* \sin \theta_r \) [see Fig. 2] has been used. Next, dividing Eq. (14a) by Eq. (15) for the case \( j = 1 \), Eq. (10) becomes

\[ \overline{y} = \left\{ (2\mu f(\eta_s)/\rho \omega \omega \omega) (r_b/r_s)^2 (2x^*/3L) \right\} I(\eta) \]  

(16)

Finally, neglecting longitudinal shock curvature, we set

\[ y_s/x^* = \tan \theta_s \]  

so that

\[ r_s/x^* = (r_b + y_s \cos \theta_r)/x^* = [1 + (\tan \theta_s/\tan \theta_r)] \sin \theta_r \]  

(17)
and by comparing Eq. (12) to the definition (2b) of $\mu$ by the use of Eqs. (16) and (17), we find

$$B = \{8\mu_b / 3\mu \tan \theta_b [1 + (\tan \theta_s / \tan \theta_b)]^2\} f(\eta_s) \alpha \quad (18)$$

Here $\alpha$ is the inverse Reynolds number $(\rho U_\infty r_b / \mu_\infty)^{-1}$ based on free-stream conditions and the local radius $r_b(x^*)$ of transverse body curvature. From Eq. (18), $B$ vanishes for two-dimensional flow ($j = 0$).

From the energy equation in the form of Eq. (8), from $u \sim \sqrt{T_0}$, and from Eqs. (13) and (16) which together relate the parameter $N$ to the streamfunction $f(\eta)$, to its derivatives, and to the local boundary conditions on the viscous layer, the viscous layer momentum equation (4a) now reduces to

$$\begin{align*}
\frac{f_{\eta\eta} - (1 + C_2 I(\eta)) f_{\eta\eta}}{\{(1 - f_\eta)(1 + C_1 f_\eta)^{1/2}\} f_{\eta\eta}} + ff_{\eta\eta} &= 0 \\
&\text{where} \\
C_1 &= A^2(T_0/T_b) \quad (20a) \\
C_2 &= (8j(\chi - 1 \frac{T_b}{T_0})^{1/2} f(\eta_s)^3 \tan \theta_b [1 + (\tan \theta_s / \tan \theta_b)]^2} M_\alpha \quad (20b)
\end{align*}$$

Equation (19) differs from the reduced viscous layer momentum equation of Ref. 6 only by the appearance of the new term $C_2 I(\eta)$. This term
introduces the effects of transverse curvature characterized by the parameter $M_a$, and it vanishes for the case of twc-dimensional flow. For the case of axial symmetric flow, only the regime $M_a \ll 1$ is treated in this work. The reason for this will be discussed in conjunction with the shock structure analysis.

Now, if $C_1$ and $C_2$ were to be treated as parameters, then for each value of $(f_{nn})_b$ greater than the value which gives the boundary layer solution ($n_s \rightarrow \infty$), a viscous layer solution would be obtained with finite shear (proportional to $N f_{nn}$) at the shock surface $n = n_s$ where $f_{nn} = u^*/u^* = 1$. The shock surface coordinates $x^*$, $y^*$ corresponding to $n_s$ are determined by 1) employing Eq. (14a) which states that mass flux into the viscous layer between the body and shock surface is conserved and 2) by matching the velocity $u^*$ and its gradient $3u^*/3y^*$ obtained with finite shear at the outer edge of the viscous layer to the respective quantities obtained at the inner edge of the shock from the shock structure solution.

III. Shock Structure

Since the flow at the shock surface has been assumed locally similar within the viscous layer model, all shock structure variables at the inner edge of the shock are single-valued functions of $n_s$.

The shock transition equations in the coordinate frame centered at the shock surface are illustrated by the continuity and tangential momentum equations.
\[ \frac{3}{\partial n} (r^J \rho v) = 0 \]  
\[ \rho v \frac{3u}{\partial n} = \frac{1}{r^J} \frac{\partial}{\partial n} (r^J \mu \frac{3u}{\partial n}) \]  

where \( n \) is the coordinate in the direction measured normal from the shock surface to the freestream, and the velocity components \( u \) and \( v \) are taken normal to and parallel to \( n \), respectively [see Fig. 2]. Based on the results of Ref. 6, the effects of including longitudinal shock curvature terms in Eqs. (21) have been neglected as small.

Integrating the continuity equation (21a) yields

\[ r^J \rho v = \text{constant} = r^J \rho_0 v_0 = r^J \rho_0 v_0 \]  

Substituting Eq. (22a) into Eq. (21b) and multiplying by \((r/r_s)^2\), the tangential momentum equation (21b) becomes

\[ \rho s v (r_s/r)^J \frac{3u}{\partial n} = (r_s/r)^J \frac{3}{\partial n} \left[ \mu (r-s)^J \frac{3u}{\partial n} \right] \]  

To solve these shock structure equations, the following reduced, dimensionless variables are introduced:

\[ \zeta = \int \frac{\rho U}{\mu} (r_s)^J \ dn \quad W = \frac{u}{U_\infty} \quad V = \frac{v}{U_\infty} \]

\[ p = \frac{\rho U}{\rho_0 U_\infty} \quad \phi = \frac{h + \frac{1}{2} v^2}{U_\infty^2} \]  

\[ p = \frac{\rho}{\rho_\infty} \]
The dimensionless forms of Eqs. (22) by (23) are then

\[ D_{V_s} = [1 + j(\Delta_s/r_s)] D_{V_s} \]  
\[ \frac{2W}{\partial \zeta^2} - D_{V_s} \frac{3W}{\partial \zeta} = 0 \]

where \( \Delta_s \equiv (r_\infty - r_s) \) denotes shock thickness. Equations (24) differ from the "zero-order" shock transition equations of Ref. 6 only by the appearance of the transverse shock curvature parameter \( \Delta_s/r_s \).

If however \( Ma \ll 1 \), then \( \Delta_s/r_s \ll 1 \) and a simple closed form solution to Eqs. (24) can be readily obtained analogous to the "zero-order" shock solution in Ref. 6. In the present model, \( Ma \ll 1 \) is satisfied and transverse shock curvature terms are neglected as small in the shock structure equations. Equations (24) then become

\[ D_{V_s} = D_{V_s} \]  
\[ \frac{2W}{\partial \zeta^2} - D_{V_s} \frac{3W}{\partial \zeta} = 0 \]

and in similar manner the normal momentum equation and the energy equation for the shock structure become

\[ \frac{3W}{\partial \zeta} + \frac{3P}{\partial \zeta} - \frac{4}{3} \frac{2W}{\partial \zeta} = 0 \]  
\[ \frac{3W}{\partial \zeta} - \frac{4}{3} \frac{2W}{\partial \zeta} + \frac{D_{V_s} W}{\partial \zeta} - \frac{3W}{\partial \zeta} (W \frac{3W}{\partial \zeta}) = 0 \]
The shock structure is taken to extend from the outer edge of the viscous layer $\zeta = 0$ to the freestream $\zeta = \infty$. At the shock surface, the shock structure flow variables and their normal gradients are required to match the corresponding viscous layer values at $\eta = \eta_s$ as given by the solution to Eq. (19).

Following Ref. 6, we now illustrate this matching procedure at the shock surface for the case of the finite tangential shear stress $\mu_s (\frac{\partial u^*_s}{\partial y^*_s})$. In terms of viscous layer variables, this stress may be written

$$ \mu_s (\frac{\partial u^*_s}{\partial y^*_s}) = (\mu/\mu)_s \cdot (\frac{\partial v}{\partial y^*_s})_s \cdot (\frac{u}{\partial y^*_s})_s $$

or

$$ (u \frac{\partial u^*_s}{\partial y^*_s})_s = O_1(j) \cdot O_2(j) \cdot \rho \frac{\mu^*}{\mu} \left( -\frac{\eta}{2f} \right)_s $$

where

$$ Q_1(j) = \begin{cases} 
[1 + \frac{1}{2} (\cot \theta - \tan \theta_b) \sin 2\theta_b] \cdot (\tan \theta / \cos \theta_b) & \text{for } j = 0 \\
[1 + (\tan \theta / \tan \theta_b)^2] \cdot (3L/2x^*_s) & \text{for } j = 1 
\end{cases} $$

$$ Q_2(j) = \frac{\sin \theta_b \cdot (1 + \tan \theta / \tan \theta_b) (x^*_s / L)}{1 + 2(\tan \theta / \tan \theta_b) [1 + (\tan \theta / 2\tan \theta_b)]} $$

On the other hand, at the inner edge of the shock, the shear is
\[ (\mu \frac{\partial u^*_s}{\partial y^*_s})_s = \rho U^2 \frac{\partial u^*_s}{\partial \zeta^*_s} \]  
\[ (\frac{\partial n^*_s}{\partial y^*_s})_s = \rho U^2 \frac{\partial n^*_s}{\partial \zeta^*_s} \]  
\[ (\frac{\partial u^*_s}{\partial \zeta^*_s})_s = \rho U^2 \frac{\partial W^*_s}{\partial \zeta^*_s} \]  
(30)

with the subscript "s" here denoting conditions at \( r = 0 \). Equating Eq. (27) to Eq. (30)

\[ (\frac{\partial W^*_s}{\partial \zeta^*_s}) = Q_1(j) Q_2(j) \left( \frac{\text{Nf}_{nn}}{2f^1})_s \right) \]  
(31)

This matching of viscous layer solution to shock structure solution at the shock surface is shown next for the case of the shock surface velocity \( u^*_s \). First, recognizing from Fig. 2 that at the freestream \( W = \cos (\theta + \theta_b) \) and \( V = -\sin(\theta + \theta_b) \), and at the shock surface \( W = (u^*_s/U)_s \) \( (u^*_s/u^*_s) = \) \( A \cos \theta_s \), the tangential momentum equation (25b) is integrated once with the result

\[ (\frac{\partial W^*_s}{\partial \zeta^*_s}) [\cos (\theta_s + \theta_b) - A \cos \theta_s] \sin (\theta_s + \theta_b) \]  
(32)

Substituting Eq. (32) into Eq. (31) and solving for the reduced velocity \( A \) at the shock surface

\[ A = \frac{u^*_s}{U} = \left[ \frac{\cos \theta_s}{\cos (\theta_s + \theta_b)} + \frac{2Q_1(j) Q_2(j) \text{Nf}_{nn}}{(2f^1)}_s \right]^{-1} \]  
(33)

For the case of flat plate flow \( j = 0 \) and \( \theta_b = 0 \), Eq. (33) reduces to the result of Ref. 6.

The shock angle in terms of the density and pressure behind the shock is obtained next by integrating the normal momentum
equation (25c) once and applying freestream boundary conditions. Neglecting the gradient term \( \frac{\partial V}{\partial \zeta} \) as small compared to \( V \) [see Ref. 5]

\[
\sin (\theta_s + \theta_b) V_s = P_s - \sin^2 (\theta_s + \theta_b) - \frac{1}{\gamma M_s^2} \quad (34)
\]

Eliminating \( V_s \) by means of Eq. (25a), the shock angle is then given by

\[
\sin^2 (\theta_s + \theta_b) = D_s (P_s - 1/\gamma M_s^2)/(D_s - 1) \quad (35)
\]

The reduced enthalpy behind the shock is sought next. Integrating Eq. (25b) twice, substituting the resulting velocity profile \( W(\zeta) \) into the energy equation (25d), and integrating twice, we obtain the result

\[
\phi_s = \frac{1}{2} (1 - \Lambda \cos \theta_s/\cos (\theta_s + \theta_b))^2 \cos^2 (\theta_s + \theta_b) \\
+ \sin^2 (\theta_s + \theta_b) + 2/(\gamma - 1) M_s^2 \quad (36)
\]

where the gradient term \( \frac{\partial W}{\partial \zeta} \) has been neglected compared to \( \phi_s \) [see Ref. 5], and where the term \( \frac{\partial V}{\partial \zeta} \) has been eliminated by use of Eq. (32).

In order to obtain the density ratio across the shock, another expression for \( \sin^2 (\theta_s + \theta_b) \) is first found by substituting \( \phi_s \)
from Eq. (36) and \( V_s \) from Eq. (25a) into the reduced equation of state

\[
P_s = \frac{\gamma - 1}{2\gamma} D_s (2\phi_s - V_s^2)
\]

Equating the resulting expression to Eq. (35)

\[
\rho_s = \frac{P_s}{P_\infty} = \frac{[(\gamma + 1)/(\gamma - 1)] P_s + 1/\gamma \eta_s^2}{P_s + [1 - A \cos \theta_s / \cos (\theta_s + \theta_b)]^2 + (1/\gamma \eta_s^2)(\gamma + 1)/(\gamma - 1)}
\]

We note here that in order to avoid the solution of a cubic equation, a term \( D_s^2 [1 - A \cos \theta_s / \cos (\theta_s + \theta_b)]^2 \), which appears after equating the expressions for \( \sin^2 (\theta_s + \theta_b) \), has been neglected in comparison with \( (D_s^2 - 1) \). This is justified on the basis that since the reduced shear \( (Nf_\eta) \) is finite but always small compared to unity, then by Eq. (33) \( A \cos \theta_s = W_s \) is always close to \( W_\infty = \cos (\theta_s + \theta_b) \); and the larger \( D_s \), the closer \( W_s \) is to \( W_\infty \). This is borne out by the numerical results.

The reduced pressure \( P_s [\eta_s(\vec{x})] \) at the shock surface has, as stated before in conjunction with Eq. (10), been assumed equal to the reduced pressure \( P_b(\vec{x}) \) on the body at the same value of \( \vec{x} \). From Eq. (10) written in the form

\[
y_s = [(2\xi)^{1/2} T_b/(\rho_s u^* T_s)] I(\eta_s)
\]

and from the definition of \( \vec{y} \) [Eq. (2a)] written in the form
\[ \overline{y}_s = \int_0^{y_s^*} \left[ (r_b + y_s^* \cos \theta_b)/L \right] dy^* = \left[ (r_s + r_b) x^* \tan \theta_s /2Ly_s^* \right] y_s^* \] (40)

we have upon elimination of \( \overline{y}_s \) and the use of Eq. (14)

\[ P_s = P_b = \frac{P_b}{\rho U_e^2} = Q_1(j) Q_3(j) \frac{y - 1}{2\gamma} \left( \frac{F}{A} \right) \] (41)

where

\[ Q_3(j) = \begin{cases} \cot \theta_s & \text{for } j = 0 \\ \frac{2(x/L) \cos \theta_b}{3[2 + (\tan \theta_s/\tan \theta_b)] (\tan \theta_s/\tan \theta_b)} & \text{for } j = 1 \end{cases} \] (42)

and where

\[ F = \frac{T_b \theta(n_s)}{T_0 \theta(n_s)} \] (43)

Therefore, if from Eq. (19) a streamfunction \( f(\eta) \) and its derivatives were to be known at \( \eta = \eta_s \), the relations (33), (35), (38) and (41) would form a closed system of four equations in the four unknowns \( A, \theta_s, D_s, \theta_b, \) and \( P_s \).

**IV. Method of Calculation**

The model as formulated imposes the following restrictions on the input gas and body properties: \( M_e \) sufficiently large such that \( c_p T_0 \theta U_e^2/2, T_b/T_0 << 1, \gamma = \text{constant}, Pr = 1, \) and \( \theta_b << 1. \)

The solution for the viscous layer streamfunction \( f(\eta) \) and for the various flow properties of interest proceeds by first
transforming Eq. (19) to the following set of first order differential equations as in Ref. 6:

\[ \begin{align*}
    f_n &= J_n = Z^{1/2} (1 + C_2 I)^{-1} g, \\
    g_n &= -Z^{1/2} (1 + C_2 I)^{-1} fg
\end{align*} \tag{44} \]

where

\[ Z = |1 - J| \ (1 + C_2 J) = I_n \tag{45} \]

The no-slip boundary conditions

\[ \begin{align*}
    f(0) &= J(0) = I(0) = 0 \quad \text{at } n = 0 \tag{46} \\
    J(n_s) &= 1 \quad \text{at } n = n_s
\end{align*} \]

are then imposed. Now, for values of the wall shear \( g(0) = (f_{nn})_b \) greater than the value which gives an inviscid flow region at the outer edge of a boundary layer \( (n_s \to \infty) \), a velocity profile with finite shear \( g(n_s) = (Nf_{nn})_s \) at the shock surface can be obtained for each station along the body within the merged layer. At each such value of \( g(0) \), the no-slip boundary conditions are fully specified. Beginning then at \( n = 0 \) with a value \( g(0) = (g(0))_n^+ \) only slightly larger than the value \( (g(0))_n^\infty \) which gives the boundary layer solution \( (n_s \to \infty) \), Eqs. (44) - (45) are simultaneously integrated out from the body surface to the shock surface for fixed
local values of $C_1$ and $C_2$. The initial guesses for these parameters are obtained from the boundary layer limit $n_s \rightarrow \infty$ with $\theta_s$ guessed to be $\theta_s = \theta_{s_{inv}}$ where $\theta_{s_{inv}} = \theta_{s_{inv}}^{\text{inv}} \quad (\gamma, M_e, \theta_b, j)$ is the inviscid shock layer value for wedges and cones given in Ref. 12. As shown in the Appendix

$$C_1 \bigg|_{n_s \rightarrow \infty} = \frac{T_0 \cos \left( \theta_{s_{inv}} + \theta_b \right)}{T_b \cos \theta_{s_{inv}}}$$

$$\theta_s = \theta_{s_{inv}}$$

$$C_2 \bigg|_{n_s \rightarrow \infty} = 0$$

$$\theta_s = \theta_{s_{inv}}$$

The numerical integration of Eqs. (44) - (45) is stopped at the first point $\eta$ reached within the viscous layer where $J = f_\eta u^*/u_s^{*} \geq 1$. The coordinate $n_s$ is the finite value of $n$ at this point, and the resulting finite values of $f(n_s), g(n_s)$ and $I(n_s)$ are used to compute $A$ and $F$ in approximate form from [see Eq. (33)]

$$A = \left[ \frac{\cos \theta_{s_{inv}}}{\cos \left( \theta_{s_{inv}} + \theta_b \right)} + \frac{2Q_1(j) Q_2(j)}{\sin 2\left( \theta_{s_{inv}} + \theta_b \right)} \frac{\gamma}{2f_{\eta=n_s}} \right]^{-1}$$

and the relation given by Eq. (43). These results are then used to provide a better value of $\theta_s$ from Eqs. (35), (38) and (41). Better values for the local parameters $C_1$ and $C_2$ are next obtained from
the relations [see Appendix]

\[
C_1 = \frac{T_0}{T_b} \left( \frac{\cos \theta_s}{\cos (\theta_s + \theta_b)} + \frac{2Q_1(j) Q_2(j)}{\sin [2(\theta_s + \theta_b)]} \frac{\eta}{2\eta_s} \right)^{-2} \tag{50}
\]

\[
C_2 = \frac{[2 + (\tan \theta_s / \tan \theta_b)] (\tan \theta_s / \tan \theta_b)}{I(\eta_s) f(\eta_s)} \tag{51}
\]

and beginning again at \( \eta = 0 \) with \( g(0) = [g(0)]^+ \), Eqs. (44) - (45) are re-integrated from the body to the shock surface \( \eta = \eta_s \).

When after such successive iterations the results at the shock surface from one cycle agree sufficiently with those values from the previous cycle, the local no-slip viscous layer solution is available. The effects of small local velocity slip and temperature jump are then computed as local perturbations from the no-slip results. The method for obtaining the local slip solution is entirely analogous to that given in Ref. 6 except that Eqs. (47) - (48) of that reference are replaced by

\[
\frac{u_s^f}{u_s^*} = (f_n b) \left( \frac{\sin \theta_b}{(3L/x^*)} \right)^{1/2} \left( \frac{1 - 21}{3} \right) Q_3 (j) \left[ (\gamma - 1) \frac{T_b}{T_0} \right]^{1/2}
\]

\[
\cdot \left[ \frac{A_{nsf}^{nsf}}{2f_{nsf}^{nsf} \eta_s} \right] \eta = \eta_s \left( (f_{nsf}^{nsf})^n \right) \eta = 0 \tag{52}
\]
and the rarefaction parameter [Eq. (35) of Ref. 6] is replaced by

\[
\frac{M_\infty C^{1/2}}{Re_{x^*,\infty}^{1/2}} = \left[ \frac{Q_1(j)}{(1 - \frac{21}{3} Q_3(j)(\gamma - 1) F)} \right]^{1/2} \left[ \frac{x^* \sin \theta_b}{3L} \right]^{3/4} / f(\eta_s)
\] (54)

The final results at \( \eta(0) = [g(0)]^{+}_{\eta_s} + \infty \) constitute the local solution at the downstream end of the merged layer. The final values there for \( C_1 \) and \( C_2 \) become the initial guesses for these parameters at the adjacent station a small distance upstream. The viscous layer equations are integrated here from \( \eta = 0 \) with \( g(0) = [g(0)]^{+}_{\eta_s} + \Delta g(0) \), where \( \Delta g(0) \) is a small increment in the surface shear \( g(0) \). Through this stepwise upstream marching method, with successive iteration cycles at each step, the velocity and state variables are computed at several stations \( x^* \) within the merged layer regime. The computation is stopped at the upstream end when the condition \( M_\infty a \ll 1 \) or the condition \( (f_\eta)_b \ll 1 \) is no longer satisfied. If the computation is carried to stations \( x^* \) farther upstream, the present model breaks down as the calculated values of \( p_a / p_\infty \) become less than unity. This occurs at values of the rarefaction parameter \( M_\infty (C/Re_{x^*,\infty})^{1/2} \) of the order of unity.
VI. Results and Discussion

Computations have been carried out in the manner indicated in the previous section. The cases considered cover the range \(20 \leq M_a \leq 25\), \(0.06 \leq T_b/T_0 \leq 0.15\) and \(0^\circ \leq \theta_b \leq 20^\circ\).

In Figs. 3 - 5 the density at the shock surface for sharp wedges is compared with measured values obtained by McCroskey, Bogdonoff and Genchi. Considering the scatter in the data, the agreement with theory would appear to be good. The theoretical shock density ratio for a \(10^\circ\) cone is shown compared with the data in Fig. 6. In contrast with a wedge having the same flow conditions and comparable angle \(\theta_b\), the shock at the same distance \(x^*\) from the leading edge is weaker on the cone. This is due to the circumferential spreading of the flow around the cone, bringing the shock wave closer to the body surface and causing the merged layer to extend farther downstream than on the wedge.

Fig. 7 presents the wedge surface pressures given by Vidal and Hartz in comparison with the theory for several values of \(\theta_b\). The strong interaction and free molecule limits given by Hayes and Probstein are also shown. Both the present theory and the data lie below the result predicted by strong interaction theory. This is also seen to be true for sharp cones as shown in Fig. 8 where the cone surface pressure by the present theory and by the strong interaction theory of Mirels and Ellinwood are compared to the experimental data in the form presented by Waldron and Hofland and Glick.
On Figs. 9 - 10 the experimental skin friction and heat transfer data obtained by Vidal and Bartz on wedges is compared with the theory, and the agreement appears to be quite good. The theoretical result for cones is given in Fig. 11 compared to experiment in the form presented by Waldron.

In view of the reasonable agreement of experimental data with the theory it would appear that the present continuum merged layer model is a satisfactory one up to rarefaction parameters $M_\infty (C/Re_{x_\infty})^{1/2} \sim 1$. This limit would correspond to distances back from the leading edge of the order of $M_\infty$ mean free paths.

Appendix

THE PARAMETERS $C_1$ AND $C_2$

By Eq. (33), the parameter $C_1$ is

$$C_1 = A^2 \frac{T_0}{T_b} = \frac{T_0}{T_b} \frac{\cos \theta_s}{\cos (\theta_s + \theta_a)} + \frac{2Q_1(j) Q_2(j)}{\sin [2(\theta_s + \theta_a)]} \frac{R_e}{\eta} \eta_s^{-2}$$  \hspace{1cm} (A-1)

To find $C_2$, an expression for the parameter $M_\infty \alpha$ is first required. To obtain this, we eliminate $\xi$ between Eqs. (14) and (15) for the case of $j = 1$ and note that $\rho_b u_b/\rho_a u_a = \gamma M_\infty P_0 T_b/(\gamma - 1) T_0^{1/2}$ from $\mu = T^{1/2}$ and the equation of state, with the result:

$$M_\infty \alpha = \frac{3 \cos \theta_b (\tan \theta_s + \tan \theta_b)(1 + (\tan \theta_s/\tan \theta_b))^2}{8 \gamma P A f^2(\eta_s)} \frac{[\gamma - 1]}{\gamma} \frac{T_b}{T_0}^{1/2}$$  \hspace{1cm} (A-2)
Using Eqs. (28) and (41) - (43) to eliminate $P_s$, we obtain then

$$C_2 = \left[ 2 + (\tan \theta_s / \tan \theta_b) \right] \left( \tan \theta_s / \tan \theta_b \right) / I(n_s) f(n_s)$$

(A-3)

from Eq. (20b).

In the boundary layer limit $n_s \to \infty$ and $g(n_s) \to 0$, we find that since $f \sim 1$ when $n \approx n_s$

$$[f(n_s)]_{n_s \to \infty} = \int f \, dn \bigg|_{n_s \to \infty} = 0$$

(A-4)

$$[I(n_s)]_{n_s \to \infty} = \int (1 - f) (1 + C_1 f) \, dn \bigg|_{n_s \to \infty} = \text{finite}$$

(A-5)

so that taking $\theta_s = \theta_{s_{\text{inv}}}$, Eqs. (A-1) and (A-3) yield

$$C_1 \bigg|_{n_s \to \infty} = \frac{T_0}{T_b} \left[ \frac{\cos (\theta_{s_{\text{inv}}} + \theta_b)}{\cos \theta_{s_{\text{inv}}}} \right]^2$$

(A-6)

$$\theta_s = \theta_{s_{\text{inv}}}$$

$$C_2 \bigg|_{n_s \to \infty} = 0$$

(A-7)

Here $\theta_{s_{\text{inv}}, \gamma, M_s, \theta, j}$ is the inviscid shock layer value for $\theta_s$ obtained from Ref. 12.
