one Service's programs on enlistments in other Services. Three different methods of analysis have been used to determine program and policy effects. An econometric model of volunteer enlistments by state using explanatory variables including the number of recruiters, youth unemployment rate, military/civilian wage and college entrance rates was used with 1972 and 1973 enlistment data. A monthly econometric time series model was also used with volunteer data in the CY71-CY73 time period with explanatory variables including military/civilian wage, number of recruiters, bonus variables, print media advertisements, unemployment rates and inter-Service variables. Finally, survey data were analyzed to estimate effectiveness of the bonus.

PREFACE

Manpower costs constitute about 56 percent of the budget of the Department of Defense, or approximately \$50 billion. The wise management of these resources is a challenging task that strains the current state of the art in management science. This report is concerned with an evaluation of manpower programs and policies which were implemented primarily to achieve the transition from a conscripted to an all volunteer Armed Service. Over \$2 billion were allocated to programs of increased pay, additional advertising and recruiting and bonus payments in order to provide more incentives for youth to volunteer for the Armed Forces. Three evaluation techniques -- econometric time series and cross sectional analyses and survey analysis -- have been used to evaluate program and policy cost effectiveness. The results of this analysis provides manpower decisionmakers with an improved capability to allocate resources within and among the Services for the military pay, recruiting, advertising and bonus programs.

David W. Grissmer
Director, Policy Analysis Department

SUMMARY

The decisions made in 1970 to achieve an all volunteer force by FY74 resulted in major budgetary increases in several programs designed to provide incentives for youth to join the Armed Forces. The major incentive program was a large pay increase given to E1-E3 personnel in all Services in order to make their wages competitive with other civilian opportunities. Major increases also occurred in advertising and recruiting budgets for each Service, and the Army and Marine Corps initiated bonus payments for selected skills. Table S-1 summarizes the budgets of incentive programs, by Service, from FY71-FY75. Each of these programs had the specific objective of increasing volunteer enlistments so as to meet quantitative and qualitative manpower requirements determined by Congress. The primary purpose of this analysis is to determine the cost effectiveness of these programs in attracting additional volunteers to each Service. The analysis was also aimed at determining the effects of changes in youth unemployment rates, college entrance patterns and various Service manpower policies on volunteer enlistments in each Service as well as the inter-Service effects of one Service's programs on enlistments in other Services. Three different methods of analysis have been used to determine program and policy effects. An econometric model of volunteer enlistments by state using explanatory variables including the number of recruiters, youth unemployment rate, military/civilian wage and college entrance rates was used with 1972 and 1973 enlistment data. A monthly econometric time series model was also used with volunteer data in the CY71-CY73 time period with explanatory variables including military/civilian wage, number of recruiters, bonus variables, print media

Table S-1

DOD	163	1531	1933	2117	2243

^aE1-E4 base pay and allowances increase due to PL 92-129.

advertisements, unemployment rates and inter-Service variables. Finally, survey data were analyzed to estimate effectiveness of the bonus. The major results of the analysis are given below.

A primary purpose of increasing incentive programs was to increase the number of high school graduates entering the service. The high school graduate is preferred over non-high school graduates by all Services because of lower training cost, lower loss rates and lower disciplinary infraction rates. Currently, there are more non-high school graduates willing to enter the service than are accepted; in the case of high school graduates, however, the demand exceeds the supply. The key to maintaining a quality volunteer force appears to lie in maintaining a proper balance between high school and non-high school graduates. The cost effectiveness of incentive programs has been evaluated in terms of the marginal cost of increasing the supply of high school graduates to each Service. Table S-2 summarizes the results of this analysis. The data in the table show the additional budgetary cost in each program of enlisting one additional high school graduate in each Service. Conclusions from the data include:

- o The additional budgetary cost of enlisting one additional high school graduate for a Service varies from \$900 if the money is placed in a unit canvasser/recruiter assistant program of the Army to \$268,000 if the money is placed in an enlisted pay raise for the Marine Corps.

- o The data show that money spent on additional pay raises to incoming personnel is the least cost effective use of resources in improving the quality or quantity of volunteers.

- o The data generally show that additional recruiting resources are the most cost effective of the measured programs, with the Army unit canvasser/recruiter assistant program by far the most cost effective of any programs measured by GRC.

- o The data show that the bonus programs are generally less cost effective than recruiting and advertising resources in attracting additional high school graduates. However, the bonus program has an additional objective of attracting personnel to key shortage skill areas which cannot be effectively fulfilled by additional recruiting or advertising resources.

Table S-2
SUMMARY OF COST EFFECTIVENESS RESULTS^a

	Army	Navy	Marine Corps	Air Force
Pay	91,000 ± 14,000	185,000 ± 55,000	268,000 ± 140,000	140,000 ± 34,000
\$1500 bonus	10,600 ^b		32,600 ^b	
\$2500 bonus	14,400 ^b		9,500 ^b	
Advertising	9,000 ± 9,000	- ^c	- ^d	2,500 ± 1,100
Regular recruiters	7,500 ± 5,600	3,300 ± 700	12,000 ± 4,800	1,400 ± 300
Canvassers	900 ± 300 ^e			

^aMeasurement is marginal cost of an additional high school graduate enlistment

^bMarginal cost was estimated from survey data and no error estimates could be made.

^cThe Navy did not provide advertising data.

^dThe Marine Corps had no paid print media insertions.

^eRobert Babiskin, *et al.*, "Cost Effectiveness of Army Recruiting and Canvasser Programs during Fiscal Year 1974," OAD-CR-51, General Research Corporation, McLean, Virginia, to be published.

o The data show that per additional dollar spent, the Air Force is able to attract more additional high school graduates than any other Service, and the Marine Corps is able to attract the least number of additional high school graduates per additional dollar spent.

o For the Services (Army and Air Force) where advertising data were available, the cost effectiveness analysis showed regular recruiting expenditures and advertising expenditures to be in balance within the error limits of the measurements.

Table S-3 gives the additional number of high school graduates that can be expected to enter each Service annually if one additional recruiter were given to each Service. The relative competitive advantage or disadvantage each Service has in enlisting youth is reflected dramatically in these recruiter data; the Air Force, for each dollar spent, is able to attract over twice as many additional high school graduates as the Navy, five times as many as the Air Force and eight times as many as the Marine Corps.

Table S-3
COMPARISON OF MARGINAL ANNUAL
PRODUCTIVITY OF SERVICE RECRUITERS

Service	Annual marginal productivity ^a
Air Force	22 ± 5
Navy	9 ± 2
Army	4 ± 3
Marine Corps	2.5 ± 1

^aAdditional high school graduates per year per additional production recruiter.

Table S-4 places the recruiter marginal productivity for each Service in perspective of youth preference and actual FY74 performance. The first column is the percentage of high school seniors who give each Service as their first preference, and thus would be expected to reflect the distribution of high school graduate enlistees if each Service had equal requirements and equally effective recruiting operations. The second column

shows the actual distribution of FY74 high school graduates among the Services. The third column shows the percentage distribution of enlistees calculated from the current marginal productivity of the recruiters in Table S-3; i.e., if additional recruiters were added by each Service, the percentage distribution of the additional recruits is reflected by the third column.

Table S-4

COMPARISON OF PERCENTAGE OF HIGH SCHOOL ENLISTMENTS EXPECTED IN EACH SERVICE FROM GILBERT YOUTH SURVEY, MARGINAL RECRUITER PRODUCTIVITY, AND ACTUAL FY74 DATA

Service	Gilbert Youth	Actual FY74	Marginal recruiter productivity
Army	25	37	11
Navy	26	25	24
Marine Corps	15	11	7
Air Force	34	27	59

Conclusions from these data include:

- o The data for the Air Force show that while 34 percent of high school graduates prefer the Air Force, the Air Force only needs 27 percent of DOD high school graduate enlistees. The high recruiter productivity number, which states that 59 out of each 100 additional high school graduates would be recruited by the Air Force, can be interpreted in terms of a queue of available high school graduates who can be obtained with little recruiter effort.

- o The Marine Corps data indicate that while 15 percent of high school graduates prefer the Marine Corps, only 11 percent ended up choosing the Marine Corps in FY74. These data plus the low recruiter productivity number, which states that only 7 out of each 100 additional high school graduates would be recruited by the Marine Corps, suggest that current Marine Corps recruiting procedures need improvement. Lack of paid media advertising and option programs for FY74 could account for part of the low productivity.

o The Navy data indicate that the Navy was able to maintain its share of the high school graduate market, and the productivity of additional recruiters would also maintain the Navy's share of the market.

o The Army data state that while only 25 percent of high school seniors prefer the Army, 37 percent of high school graduate enlistees chose the Army in FY74. The Army was thus able to recruit high school graduates who preferred other Services. Advertising, extensive use of canvassers and attractive options probably account for part of these results.

The average of the unemployment elasticities derived for the 1972-1973 cross-sectional measurements are given in Table S-5, together with estimates of effects of changes in unemployment.

Table S-5
SUMMARY OF POTENTIAL UNEMPLOYMENT
EFFECTS ON VOLUNTEER ENLISTMENT

	Army	Navy	Marine Corps	Air Force
Elasticity	.12 ± .11	.18 ± .12	0	.09 ± .09
Potential effect ^a	2.4	3.6	0	1.8

^aPercentage change in high school graduate enlistments of a 20 percent change in unemployment rate.

The range of variation of the unemployment indices of the nation is usually between 4 and 6 percent, or a 20 percent variation around 5 percent. The second row of Table S-5 shows the percentage change in high school graduate volunteer enlistments of a 20 percent unemployment change. Conclusions from these data are:

o Marine Corps enlistments are relatively insensitive to changes in unemployment rates, while other Services show relatively small sensitivity to unemployment rates.

Table S-6 gives the estimated RMC pay elasticities from the time series measurements, and the estimated effect of a 10 percent change in the relative RMC military pay/civilian pay ratio on volunteer enlistments.

Table S-6

SUMMARY OF POTENTIAL RMC MILITARY PAY/CIVILIAN PAY
RATIO ON HIGH SCHOOL GRADUATE ENLISTMENTS IN EACH SERVICE

	Army	Navy	Marine Corps	Air Force
Elasticity	.76 ± .12	.44 ± .13	.15 ± .08	.53 ± .13
Potential change ^a	7.6	4.4	1.5	5.3

^aPercentage change in high school graduate enlistments of a 10 percent change in RMC military pay/civilian pay ratio.

Conclusions from these data include:

- o Marine Corps high school graduate enlistments are relatively insensitive to a pay raise.
- o The Army shows the highest pay elasticity of all Services for high school graduates.

Other conclusions from the analysis include:

- o Marine Corps high school graduate enlistments were relatively insensitive to incentive program effects, thus increases in Marine Corps accession requirements will be met mainly by non-high school graduates.
- o Queues exist for Air Force high school graduate enlistments; thus, of all Services, the quality of Air Force enlistments would be least sensitive to recruiting and advertising budget cuts.
- o No effect could be detected on Air Force or Navy enlistments of the \$1500 and \$2500 bonus programs of the Army and Marine Corps.
- o Wide changes in Navy quotas do affect Air Force enlistments. Roughly, for each change of 1000 in monthly Navy enlistments, a change of 100 is expected in Air Force high school graduate enlistments.
- o The current marginal cost of placing a Service recruiter in the field, averaged over all Services, is \$30,000 annually. The GRC estimated recruiter marginal costs by Service are given in Table S-7. One factor that may affect the increased marginal productivity of the Air Force recruiter and the decreased productivity of other Service recruiters is the level of support costs of the recruiter which is much higher for the Air Force than for the other Services.

Table S-7
RECRUITER MARGINAL COST DATA

	Army	Navy	Marine Corps	Air Force
Initial investment cost	3,900	3,200	3,150	10,300
Annual recurring cost	25,500	25,200	27,000	32,300
Total annual cost ^a	27,500	26,800	28,600	37,500

^aInitial investment cost spread over 2-year period.

Other, more detailed conclusions are given at the ends of Chaps. 2-6.

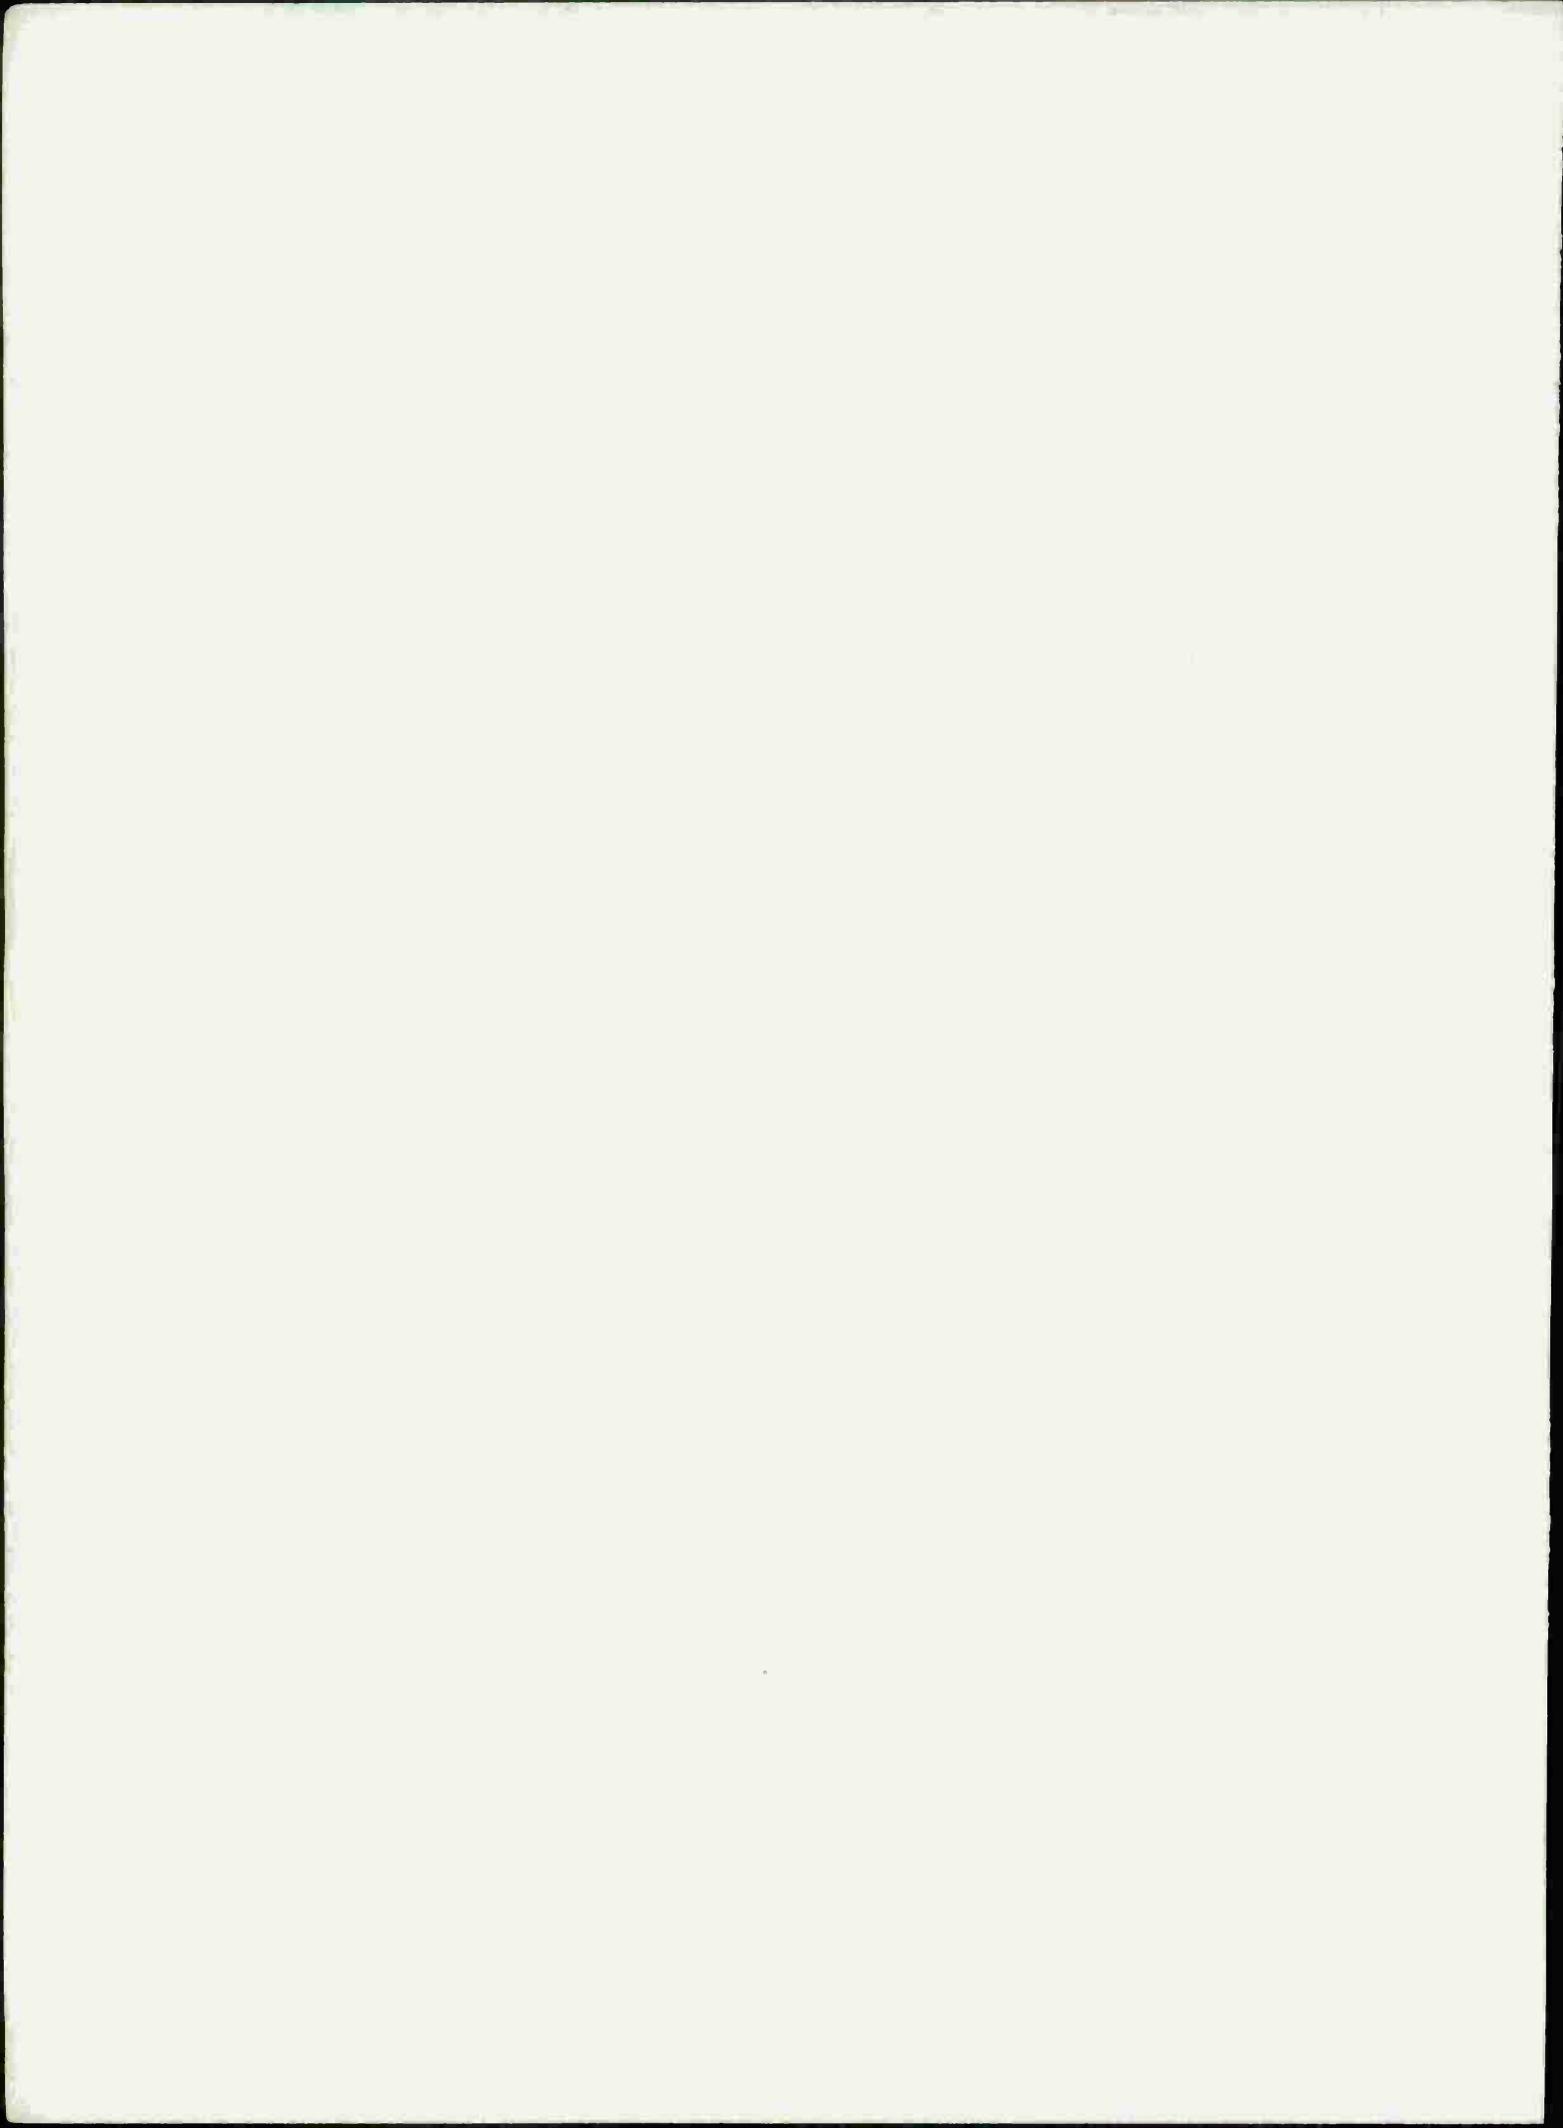

RECOMMENDATIONS

Major budget recommendations arising from this analysis have been prepared in a separate POM issue paper written by GRC. Other recommendations include:

- o The Air Force, Navy and Marine Corps should place more emphasis on programs similar to the Army's recruiter assistant/unit canvasser program.

- o Additional study should be made comparing the recruiting operation of the various Services with respect to recruiting costs, recruiter selection, recruiter location, recruiter training and general mode of operation. The substantial differences found in inter-Service recruiter productivity and between canvassers and regular recruiters suggest that substantial increases in productivity might be achieved by more detailed study of recruiting efforts.

- o Many of the ambiguities in the current analysis could be eliminated by a pooled time series cross-sectional analysis of enlistments, and should be undertaken. Such an analysis could provide a sound analytical basis for budget recommendations, year after year, for incentive programs for each Service.

Chapter 1

INTRODUCTION

The decisions made in 1970 to achieve an all volunteer Armed Force by FY74 resulted in large budgetary increases in several programs designed to provide incentives for youth to join the Armed Forces. The major incentive program was a substantial pay raise given to E1-E3 personnel in all Services to make their wages competitive with civilian wage rates. Major increases also occurred in recruiting and advertising expenditures for each Service and the Army and Marine Corps initiated bonus payments. Table S.1 provides the budgetary estimates for these programs since FY71.

Each of these programs had the clearly defined objective of increasing volunteer enlistments so as to meet the quantitative and qualitative manpower requirements determined by Congress. The bonus had the additional objective of filling certain key skill requirements where shortages existed.

The primary purpose of this analysis is to evaluate the cost effectiveness of these programs in attracting volunteers to each of the Services. Three different methods of analysis have been used to determine the effectiveness of these budgeted programs as well as the effect of other variables such as unemployment and educational propensity on enlistments. A cross-sectional analysis of state data for 1972 and 1973 for each Service is described in Chap. 2. Data used in the analysis include by state the number of recruiters, qualified military availables, percentage of youth going to college, military/civilian pay ratio, youth unemployment rates and military/civilian population. Dependent variables include volunteer enlistments for different educational and AFQT groups. A time series analysis on FY71-FY73 data has also been done for each Service. The results are described in Chaps. 3-6. Independent variables included in

this analysis include military/civilian pay ratio, number of recruiters, number of options, print media advertisements, unemployment rates, and quotas as well as policy variables. Dependent variables were volunteer enlistments in different educational and mental category groups. Chapter 7 contains the results of an analysis of AFEES survey results on the cost effectiveness of the bonus. Chapter 8 summarizes the measurements and provides cost effectiveness results.

Chapter 2

A CROSS-SECTIONAL ANALYSIS OF THE SUPPLY ELASTICITY OF FIRST-TERM VOLUNTEER ENLISTMENTS WITH RESPECT TO UNEMPLOYMENT RATES AND RECRUITING STRENGTH

INTRODUCTION

Previous studies which purport to measure the supply elasticity of first-term enlistments with respect to unemployment rates and recruiting strength have been sparse and fragmented. The models used in previous studies did not include the same variables, were estimated using data taken from different time periods, were not applied uniformly to each Service and to DOD total, and in general the models provide results which are greatly divergent.

The objectives of this analysis are twofold. The first is to extend the scope and comprehensiveness of previous studies which assess the supply elasticity of first-term volunteer enlistments with respect to unemployment rates and recruiting strength. The second is to utilize a consistent modeling approach for all four Services and DOD total so that a comparative assessment of unemployment elasticities and recruiting elasticities between Services and DOD total may be made. This chapter is divided into eight sections.

1. Findings of Previous Studies
2. Specification of Models
3. Summary of Empirical Results
4. Analysis of Findings - Individual Services and DOD Total
5. Analysis of Findings - Comparison of Services
6. Analysis of Black Volunteers
7. Interpretation of Results - Problems and Pitfalls
8. Conclusions

FINDINGS OF PREVIOUS STUDIES

During the past decade several studies have been performed which assess the supply elasticity of first-term volunteer enlistments in the Armed Services with respect to changes in wages, unemployment rates, and recruiting strength. Of particular relevance to the report are those studies performed by Fisher,¹ Fechter,² Cook,³ Altman,⁴ Gray,⁵ Bennett, Haber and Kinn,⁶ and Binkin and Johnston.⁷

All studies, except Fisher, used first-term volunteer enlistments per qualified military availables (QMA) as the dependent variable. Fisher used the total number of 18-19 year-old males to calculate the accession rate. The number of independent variables in each model varied somewhat. However, all regression equations included a pay variable and all but two, Fechter and Gray, included an unemployment variable. Altman and Binkin and Johnston included a variable for racial composition; Bennett, Haber, and Kinn included a variable for recruiter productivity; Gray included a variable for distinguishing enlistments for Southern States; and Fechter's model included additional variables representing casualties

in Southeast Asia, the Berlin crisis, the Cuban missile crises, and quarterly seasonal variables.

Table 1 presents the findings of these studies. Fechter, Cook, and Fisher utilize time series models and Altman, Gray, Bennett, Haber and Kinn, and Binkin and Johnston utilize cross-sectional models. The most recent studies are those performed by Bennett, Haber and Kinn and Binkin and Johnston. Both of these studies used 1970 cross-sectional data. Gray used cross-sectional data for 1964 and Altman used cross-sectional data for 1963. Fisher's quarterly time series extended from the third quarter 1957 to the third quarter 1965. Fechter's quarterly time series is more comprehensive and extends from the first quarter 1958 to the fourth quarter 1968. Cook's quarterly time series extends from the first quarter 1958 to the second quarter 1967.

Although at least one model was constructed for each Service and DOD total, each author did not model every Service. Fisher's model was for DOD total, Fechter's model was for the Army, and Cook's models were for the Air Force. Altman modeled DOD total and the Army. Gray modeled the Army, Navy, Marine Corps, and Air Force, but did not model DOD total. Bennett, Haber and Kinn also modeled all four Services and did not include DOD total. Binkin and Johnston modeled only the Army.

The age groups and mental categories are generally comparable in all studies. However, Binkin and Johnston estimated separate elasticities for 18, 19 and 20 year olds, respectively. Fisher estimated elasticities for 18-19 year olds, and Cook included 16 year olds in his studies. The mental groupings were for either Categories I-II or Categories I-III.

The mathematical forms used in these studies are varied, but the findings of Bennett, Haber and Kinn, Altman, and Gray imply that the choice of functional forms does not significantly alter the conclusions. This conclusion is substantiated further by GRC's findings in this study. The sample sizes ranged from nine in the case of Altman to 51 in the case of Binkin and Johnston. Altman collected data on a regional basis, whereas the authors of the other cross-sectional studies collected data on a state basis. The availability of the 1970 census data facilitated the studies of Bennett, Haber and Kinn and Binkin and Johnston.

Table 1
STUDIES OF SUPPLY ELASTICITIES FOR FIRST-TERM ENLISTMENTS

Study	Sample period	Service	Age group	Mental group	Functional form	Sample size	R ²	-R ²	Elasticities

N Variable not in regression

** Significant at the 90 percent confidence level.

*** Significant at the 95 percent confidence level.

In most of the studies the coefficient of multiple correlation (R^2) was reported as adjusted for degrees of freedom (\bar{R}^2). Binkin and Johnston reported both the adjusted and unadjusted figures. The overall range in the adjusted coefficient was from -.03 in Binkin and Johnston to .88 in the Fisher study. The minus coefficient is possible because the unadjusted coefficient was very small.*

The adjusted coefficient of multiple correlation was higher for the time series models than for the cross-sectional models. In general, the adjusted coefficient of multiple correlation proved to be less than .5. In fact, low readings were predominantly the case in the more recent studies, i.e., 1970. The implication is that a substantial amount of the variation in the dependent variable (volunteers per QMA) is not explained by the variation in the independent variables (relative wages, unemployment rates, and others), and consequently the elasticities must be interpreted with caution. Problems of interpreting the elasticities are discussed in the section Interpretation of Results - Problems and Pitfalls.

Army

For the Army the wage elasticities ranged in value from -.79 in the Binkin and Johnston study to 1.77 in the Gray study. Only Binkin and Johnston found a negative wage elasticity and Fechter, Altman, and Gray found that the wage elasticity was greater than unity. Bennett, Haber and Kinn found that the addition of a variable reflecting the impact of recruiter productivity produced smaller values for both the wage elasticity and the unemployment elasticity. In general the wage elasticities were found to be significant at the 90 percent confidence level in the range between .5 and 1.5.

The unemployment elasticities ranged in value from -.12 in the Binkin and Johnston study to .41 in the Altman study. Fechter did not

*The adjusted coefficient is given as \bar{R}^2 .

$$\bar{R}^2 = R^2 + \left[\frac{1-k}{n-k} \right]$$

where

k is the degrees of freedom
n is the sample size.

include an unemployment variable in his model. Gray estimated one equation without an unemployment variable and one equation with an unemployment variable. He found that the pay elasticity decreased from 1.77 to 1.01 with the addition of the unemployment variable. Only Altman and Binkin and Johnston found the unemployment variable significant at the 90 percent level or higher.

The study performed by Bennett, Haber and Kinn was the only one that included a variable for recruiter productivity. In this study they used the ratio of recruiters to QMAs as the recruiter productivity variable. It is interesting to note that the recruiter variable proved to be significant in more instances than the pay variables and the unemployment variables. In addition, all the unemployment elasticity coefficients were less than .1 and none were significant.

Altman finds unemployment rates significant at the 90 percent level and Binkin and Johnston find unemployment rates for 18 year olds significant at the 95 percent level. Bennett, Haber and Kinn found that the unemployment elasticities were not significantly different from zero.

Air Force

For the Air Force, the wage elasticities ranged in value from .64 in the Bennett, Haber and Kinn study to 2.23 in the Cook study. Gray found a wage elasticity of 1.27. As in the case of the Army, Bennett, Haber and Kinn found that the addition of a variable reflecting the impact of recruiter productivity produces smaller values for both the wage elasticity and unemployment elasticity. In general, the wage elasticities were found to be significant at the 95 percent confidence level.

The unemployment elasticities ranged in value from .22 in Cook's study to .34 in the Bennett, Haber and Kinn study. Gray did not explicitly include an unemployment variable in his model. Bennett, Haber and Kinn found that unemployment was significant for the Air Force at the 90 percent confidence level. The unemployment elasticity in Cook's model was not found to be significant.

The study performed by Bennett, Haber and Kinn was the only one that included a variable for recruiter productivity. As in the case of the Army, they used the ratio of recruiters to QMAs as the recruiter productivity variable. They found the recruiter elasticity to be approximately .6 and significant at the 95 percent confidence level.

Navy

The only analyses performed for the Navy were given by Gray and Bennett, Haber and Kinn. They found the wage elasticities to be negative (-.17) and nonsignificant. On the other hand, Gray found that the wage elasticity was significantly positive (.82) at the 90 percent confidence level. Gray's model did not specifically include an unemployment variable, and Bennett, Haber and Kinn found that the unemployment elasticity for the Navy was small and not significantly different from zero.

Gray's model did not include a variable for recruiter productivity. Bennett, Haber and Kinn found that recruiter productivity was positive (.62 and .59) and significant at the 95 percent confidence level.

Marine Corps

Only Gray and Bennett, Haber and Kinn provided models of the Marine Corps. Gray found the wage elasticity negative (-.12) and not significant, whereas Bennett, Haber and Kinn found the wage elasticity to be positive (.43, .55, .39, and .48) and significant at the 90 percent confidence level.

Gray's model did not specifically include an unemployment variable and Bennett, Haber and Kinn found that the unemployment elasticity was positive (.07, .15, .15, and .23) but not significant.

Gray's model did not include a recruiter productivity variable, and Bennett, Haber and Kinn found that the recruiter elasticity was positive (.34, .28, .34, and .31) and significant at the 95 percent confidence level.

DOD Total

Only Fisher and Altman modeled the enlistment responses for the combined Services. Both Fisher's model and Altman's model included variables for recruiter productivity. The empirical elasticities in Altman's model were uniformly higher than the elasticities found by Fisher. Altman found the wage elasticity to be .8 and significant at the 95 percent confidence level, whereas Fisher found the wage elasticity to be only .46 and significant at the 95 percent confidence level.

Altman found the unemployment elasticity to be positive (.34) and significant at the 95 percent confidence level. Fisher found the unemployment elasticity to be positive (.18) but not significant.

Summary of Previous Studies

The models used in previous studies did not include the same variables, were estimated using data taken from different time periods, and were not applied uniformly to each Service and DOD total. Therefore, it is not possible to make conclusive statements regarding the comparability of the results between models and among the sources. However, it is possible to make generalizations regarding these findings.

Table 2 summarizes the range of elasticities found for each of the four Services and DOD total. Wage elasticities tended to be positive and significant for all Services and DOD total. The Army and Air Force appeared to have the strongest wage elasticities. Unemployment elasticities tended to be low, positive, and not significant. The Navy and Marine Corps had the lowest unemployment elasticities. Only the models of Bennett, Haber and Kinn and Binkin and Johnston measured recruiter elasticities. All the recruiter elasticities were positive and significant.

Table 2
SUMMARY OF ELASTICITIES

Service	Elasticity ranges		
	Wages	Unemployment	Recruiters
Army	-.79 to 1.77	-.12 to .41	.28 to .69
Air Force	.55 to 2.23	.22 to .34	.60 to .62
Navy	-.17 to .82	-.04 to .02	.59 to .62
Marine Corps	-.12 to .55	.07 to .23	.28 to .34
DOD total	.46 to .81	.18 to .34	-

SPECIFICATION OF MODELS

The models used in this analysis are similar to the models used by Bennett, Haber and Kinn in that they regress the rates of volunteer accessions per QMA against the variables of relative military pay, rate of unemployment, and amount of recruiter productivity. The primary differences are in the definitions of the variables and the inclusion of two additional explanatory variables and use of 1972 and 1973 volunteer data. Specifically, these differences are:

1. Unemployment rates in this study are disaggregated into rates for 17-18 year olds and 19-21 year olds.*

2. The relative military wage is constructed using the ratio of the discounted present value of military pay to the discounted present value of the expected minimum of civilians in each age group. A 3-year time period is used for both military pay and civilian pay. The construction of the pay index is discussed in App A.

3. The two additional independent or explanatory variables are: (a) the ratio of male high school graduates to male college enrollments and (b) the ratio of military to civilian citizens.

4. Cross-sectional data by state were used for all four Services and DOD total.

The general form of the model used for the four Services and DOD total is given as

$$Y_{ij} = f[W_i, U_i, R_{ij}, H_i, M_i] \quad \begin{array}{l} i = 1, \dots, 47 \\ j = 1, \dots, 5 \end{array}$$

The variables and subscripts are defined in Table 3. The recruiting districts for the Army, Air Force, Navy and Marine Corps do not have comparable boundaries and, therefore, in order to construct models in which meaningful comparisons could be made it was necessary to convert the recruiter data to recruiters per QMA by state. The use of the state as the basic data element for the cross-sectional models permitted the construction of models for all four Services and DOD total that could be compared and evaluated with respect to unemployment rates and recruiter strength.

In all, 46 states and the District of Columbia were included in the sample. New York and New Jersey were eliminated from the sample because

* Bennett, Haber and Kinn used unemployment figures which included all age groups of the population. While the aggregate figures do include the figures for 17-21 year olds and will be correlated somewhat with these figures, it can be demonstrated that the variation in unemployment rates for 17-21 year olds is substantially greater than the variation in unemployment rates for the whole population. Therefore, they failed to observe properly the variations in unemployment rates which are applicable to volunteer accessions.

Table 3
DEFINITION OF TERMS - CROSS-SECTIONAL MODEL

Term	Definition
i	The subscript identifying the state, $i = 1, \dots, 47$
j	The subscript identifying the Service, $j = 1, \dots, 5$
Y_{ij}	The number of first-term volunteer enlistments per 1000 QMAs per state for the j^{th} Service
W_i	The relative military wage, i.e., the ratio of military wages to civilian wages, per state
U_i	The rate of unemployment per state per age group, i.e., 17-18 or 19-21
R_{ij}	The number of recruiters from the j^{th} Service per 1000 QMAs per state
H_i	The ratio of male high school graduates to the number of male college enrollments per state
M_i	The ratio of military residents to the total number of residents per state

of recruiting district boundary changes between 1972 and 1973 for both the Army and the Navy. Hawaii and Alaska also were eliminated from the sample. The Army implemented substantial changes in the boundaries for the recruiting main stations (RMS) in 1972 and, therefore, the recruiter variable was not included in the Army and DOD total models for 1972. GRC has performed an in-depth cross-sectional analysis of unemployment rates with the recruiter variable included in the model for 1972 for RMS that did not have boundary changes, and the results of that study have been included in the report for comparative purposes.⁸

A stepwise regression program was used, and in all, 80 regression fits were made. Eight different models based on age, mental category, education, and race were estimated for each Service and DOD total for both calendar years 1972 and 1973. The models are as follows:

1. 17-18 year olds
2. 19-21 year olds
3. Mental Category I-II
4. Mental Category I-III
5. High school graduates
6. Non-high school graduates
7. High school graduates - black
8. Non-high school graduates - black

Initially, the data were fitted to three mathematical forms: (1) linear, (2) log-linear, and (3) semi-log. The elasticities derived from each form were not significantly different and, as such, confirm the previous studies of Bennett, Haber and Kinn that the choice of form does not materially alter the results. As a result of this finding and also due to the large number of regressions that were required in this study, it was considered uneconomical to use more than one mathematical form. The linear model was used in all cases and is given as:

⁸W. S. Moore, "An Analysis of the Supply Elasticity of First-Term Army Volunteer Enlistments with Respect to Unemployment Rates," Chap. 6 in D. W. Grissmer, et al., An Evaluation of Army Manpower Accession Programs, General Research Corporation, McLean, Virginia, OAD-CR-37, April 1974.

$$Y_{ij} = B_0 + B_1 W_i + B_2 U_i + B_3 R_{ij} + B_4 H_i + B_5 M_i \quad i = 1, \dots, 47$$

$$j = 1, \dots, 5$$

The rationale for including the ratio of male high school graduates to college enrollments is based on the assumption that the propensity of a high school graduate to enlist is less if he goes to college. Presumably, a high ratio will be associated with a high percentage of volunteer enlistments. As will be seen, the regression results confirm this hypothesis.

The rationale for including the percentage of military population in each region is based on the premise that the career selections of young individuals are influenced by the careers of parents and friends. If a large proportion of the population in a region is employed by the military, then there should be a higher probability that career choices will be made in favor of the military than if there were a smaller proportion of military population.

The empirical findings of the regression models are given in the next section, Summary of Empirical Results.

SUMMARY OF EMPIRICAL RESULTS

The empirical results of the regression models are presented in Tables 4-13. Tables 4, 5, and 6 summarize the regression results for the Air Force, Marine Corps and Navy, respectively. The results from the Army and DOD total are presented in Tables 7, 8, 9, 10, and 11. Table 12 presents results for black volunteers. The first column in the table defines the regression models in terms of the dependent variable, i.e., volunteer category, used. Columns two through six contain the elasticities for each of the independent variables appearing in the models, i.e., unemployment rates, relative pay, high school graduates to college enrollments, military population density, and recruiters.

Some of the cells in the tables do not contain entries. This resulted from the use of a stepwise regression program. The stepwise regression program automatically purges all variables from the model that are not significant in explaining the variation in the dependent variable, and for statistical purposes these variables may be regarded as ineffective explanatory variables in the models in which they appear.

The results of the regression runs are presented in the form of elasticities, not regression coefficients. Elasticity measures the percentage change that takes place in the regressand (i.e., the dependent variable) as a result of a percentage change in one of its regressors (i.e., independent variables), while holding all other regressors constant. More formally, point elasticity in the multivariate case is given by

$$\epsilon = \frac{\partial Y}{\partial X_i} \left[\frac{X_i}{Y} \right]$$

where Y is the regressand and X_i one of its regressors. ($\partial Y/\partial X_i$ is the regression coefficient of X_i .) The elasticity associated with a regressor will depend on the selection of values for X_i and Y. Elasticity will vary therefore with the changes in these values and cannot be regarded as constant for any given relationship. For the purposes of this study all elasticities were calculated at the mean (\bar{X}_i/\bar{Y}), i.e., at the centroid.

It is to be noted that a number of entries in the tables are marked with asterisks. Entries without asterisks were not found to be statistically different from zero. Those found to be significant were coded as follows:

- *: Entry is significant at the 68 percent confidence level
- ** : Entry is significant at the 90 percent confidence level
- ***: Entry is significant at the 95 percent confidence level

As noted in the previous section, reliable state data for Army recruiters could not be derived for 1972 because of the changes in the recruiting boundaries that occurred. As a result, the regression runs for 1972 excluded the recruiter variable (see Table 8). State data for Army recruiters were obtainable for 1973 and regression runs were made with and without the recruiter variable in the model. Table 9 summarizes the results for Army 1973 with the recruiter variable in the model, and the results for Army 1973 without the recruiter variable are incorporated in Table 8 with the 1972 data.

Table 7 summarizes the results of the GRC Army 1972 elasticity study.⁹ These results are based on using the RMS as the basic data

⁹ Ibid.

element rather than the states, i.e., all data have been converted to RMS boundaries. While these results are not directly comparable with the results obtained from the models using state boundaries, they do provide a useful method of comparing the results for consistency.

Since the recruiting variable was omitted from the Army 1972 models, it also had to be omitted from the DOD total model for 1972. Table 10 summarizes the results for the regression runs made for DOD total without the recruiting variable for both 1972 and 1973. Table 11 summarizes the results for the regression runs made for DOD total with the recruiter variable included for 1973.

Limited information on black volunteers restricted attention to the year 1973 and concentrated on the two categories of high school graduates and non-high school graduates. Table 12 summarizes the regression results for black volunteers.

Unemployment rates appearing in this study were obtained on a state-by-state basis for the 17-18 and 19-21 age groups. Rates for both groups were used when dealing with overall volunteers in the two age categories. In all other cases, a weighted unemployment rate was used. The weights were based on the actual distribution of 17-18 and 19-21 year olds for each Service. This weighting system is described in App B.

As noted in the preceding section, the pay variable used in this study is the ratio of military to civilian wages. Civilian pay scales were based on industrial wages in the 17-18 and 19-21 age groups and it should be recognized that this practice may create distortions for those states not possessing dense concentrations of industrial activity. Separate wage variables were used in the two age categories. It was found that these variables are closely associated and consequently only the 19-21 year old pay scale was used in the other volunteer categories, i.e., Mental Categories I-II and I-III and education categories -- high school graduates and non-high school graduates.

An analysis was made to determine the degree of multicollinearity present in the relationships. An examination was made of the correlation matrices associated with each regression, and it was concluded that sufficient levels of correlation exist among the independent variables to increase the calculated variances of their estimated regression coefficients. However, multicollinearity was not present to a degree that would seriously impair the estimated elasticities, i.e., at no time did the correlation among any pair of regressors exceed 0.5 and most were well below this figure.

Several tests were made to detect the presence of autocorrelation. Regression runs made for aggregate (as opposed to black only) volunteers were checked by means of the Durbin-Watson test and no significant evidence was found to indicate the presence of serial correlation. Runs involving black volunteers were checked by means of nonparametric tests for randomness in the residuals (the Durbin-Watson method could not be used due to an insufficient number of sample points). No evidence of autocorrelation was found using the nonparametric tests.

As was noted earlier, elasticities are not fixed for any supply function but rather vary along its length. This study has chosen to determine the elasticity of each independent variable at the point of the sample means. The reader may wish, however, to consider a different point on one or more of the relationships considered. The appropriate elasticity can be calculated by multiplying the regression coefficients times the selected values for X_i and Y_i , e.g., X_i/Y_i . The regression coefficients for the regression runs are given in Table 13.

ANALYSIS OF FINDINGS - INDIVIDUAL SERVICES AND DOD TOTAL

This section describes the analysis and findings of the regression models for the Army, Air Force, Marines, Navy, and DOD total. This section reports only the analysis and findings of the Services and DOD individually, and no attempt is made to compare similarities and differences among them. The analysis of the comparisons among the Services and DOD total is reported in the following section.

For each Service and DOD total the volunteer categories were grouped into pairs on the basis of mental classification (I-II and I-III), education (high school and non-high school), and age (17-18 and 19-21). The

primary objective was to assess the significance of unemployment and recruiting strength in explaining the variation in volunteer enlistments for each Service. Comparisons were made to ascertain if differences existed within the volunteer pair groupings for each year, e.g., was there a difference between 17-18 year olds and 19-21 year olds in 1972.

Regression runs were made for both 1972 and 1973, and a nonparametric test of significance was made for each Service and DOD total to determine if the pattern of results among volunteer categories differed from one year to the next.¹⁰

Army

Three regression models were used to analyze volunteer enlistments for the Army.

1. RMS Model 1972
2. State Model 1972-1973, without Recruiters
3. State Model 1973

The RMS model was based on 34 sample observations from different RMS for calendar year 1972, whereas the state models were based on 47 sample observations from the different states for calendar years 1972 and 1973. In the RMS model, the variables for pay, unemployment, high school to college ratio, and military population density were converted from state boundaries to RMS boundaries. In the state models, the recruiter variable was converted from RMS boundaries to state boundaries. The algorithm used to convert the data from state to RMS and vice versa was based on total population within ZIP code areas for both the states and RMS.

The models are not directly comparable because the data are based on different geographic boundaries. However, the models are comparable to the extent that the values of the independent variables, i.e., relative pay and unemployment rates, are proportionate to population totals, and it was felt that the results from the RMS model should be included as a supplement to the state models. The overall results of the RMS model are summarized in Table 7, and the results of the state model are summarized in Tables 8 and 9.

¹⁰The test used was a variation of the McNemar test of significance utilizing the binomial test. See S. Siegel, Nonparametric Statistics for the Behavioral Sciences, McGraw-Hill, 1956.

Analysis of Unemployment Elasticities. The unemployment elasticities for the state models and the accompanying 90 percent and 95 percent confidence intervals are presented in Table 14. The results are given for the 1972 state model without a recruiter variable, the 1973 state model without a recruiter variable, and the 1973 state model with a recruiter variable. A number of conclusions may be drawn from these results:

1. The unemployment elasticity was positive and significant in 1972.
2. Unemployment had little or no impact on volunteer accessions in 1973.
3. The unemployment elasticities were consistently greater for 17-18 year olds than 19-21 year olds.
4. The unemployment elasticities were consistently greater for Category I-II than Category I-III .
5. The unemployment elasticities were slightly higher for the high school category than for the non-high school category.
6. The presence of the recruiter variable in the model did not significantly impact the value of the unemployment elasticity in 1973.

The results of the regression runs utilizing 1972 state data indicate that unemployment was a significant variable for all volunteer categories tested except 19-21 year olds. Category I-II had the highest unemployment elasticity of .34 which was significant at the 95 percent confidence level, and 19-21 year olds had the lowest value, .098, which was not significantly different from zero at the 68 percent confidence level.

The unemployment elasticity for 17-18 year olds was 137 percent larger than that for 19-21 year olds. It was 33 percent larger for Category I-II than Category I-III, and it was only 16 percent larger for high school graduates than non-high school graduates. It is interesting to note that there did not appear to be a large difference between the unemployment elasticities for the high school graduates and non-high school graduates.

The results for the regression runs utilizing 1973 state data without a recruiter variable in the model indicate that unemployment was not a significant variable in determining volunteer enlistment for the year. The only volunteer group that was significant was Category I-II at an elasticity of .155 and significant at the 68 percent confidence level.

Table 14
ARMY UNEMPLOYMENT ELASTICITIES - STATE MODELS

Volunteer category	Unemployment elasticity	90% CI	95% CI
	<u>1972 without Recruiters</u>		
17-18	.232 ^{**}	.033 to .430	-.109 to .470
19-21	.098	-.145 to .351	-.193 to .389
I-II	.340 ^{***}	.094 to .585	.044 to .634
I-III	.255 ^{***}	.078 to .432	.044 to .467
High school	.230 ^{**}	.017 to .442	-.024 to .484
Non-high school	.198 [*]	-.085 to .481	-.141 to .538
	<u>1973 without Recruiters</u>		
17-18	.102	-.094 to .297	-.133 to .335
19-21	-.110	-.364 to .144	-.415 to .195
I-II	.155 [*]	-.064 to .373	-.108 to .417
I-III	.078	-.109 to .263	-.146 to .301
High school	.066	-.126 to .259	-.164 to .297
Non-high school	-	-	-
	<u>1973 with Recruiters</u>		
17-18	.102	-.094 to .297	-.133 to .335
19-21	-.075	-.336 to .186	-.389 to .239
I-II	.074	-.129 to .277	-.170 to .318
I-III	.078	-.109 to .263	-.146 to .301
High school	-	-	-
Non-high school	-	-	-

* Significant at the 68 percent confidence level.

** Significant at the 90 percent confidence level.

*** Significant at the 95 percent confidence level.

The results are consistent with the 1972 model in that the elasticities for 17-18 year olds were greater than the 19-21 year olds, the Category I-II were greater than Category I-III, and high school graduates were greater than non-high school graduates (in the sense that the non-high school variable did not enter the stepwise regression). The negative elasticities obtained for 19-21 year olds were not significantly different from zero and their occurrence may be considered due to random variation.

The McNemar nonparametric test was run to determine if there was a shift in significance of unemployment from 1972 to 1973. The results of the test confirmed the hypothesis that there was a significant difference in the unemployment level and that this difference could be asserted with 95 percent confidence.

The addition of a recruiter variable to the model had only a slight impact on the value of the unemployment elasticities. The elasticity for Category I-II was not significant in this case and it was approximately one-half the value without the recruiter variable. Also, neither the high school nor the non-high school variable entered the regression model.

Perhaps the most significant finding of the analysis is the shift in the impact of the unemployment variable. This shift can be explained in part by the fact that unemployment rates were much lower in 1973 than 1972. Remembering that the formula for elasticity is

$$\frac{\partial Y}{\partial X} \left[\frac{\bar{X}}{\bar{Y}} \right]$$

it can be seen that the elasticity for 1973 should be lower since the average unemployment rate (\bar{X}) was lower in 1973 than 1972.

If one subscribes to the hypothesis that there is a certain amount of structural unemployment at all times, i.e., people who are in the transitional phase between jobs or those who have just entered the labor force and are still unemployed, and if it is accepted that labor markets were relatively tight in 1973, it might be concluded that unemployment had reached or approached a theoretical minimum, and this level would be such that small changes around the margin would have little impact on volunteer enlistments, thus accounting for the observed change in elasticities.

The finding that unemployment elasticities might shift from one year to the next as a result of changes in the labor market suggests that it may not be practical to compare elasticity studies conducted during different time periods, even if the research methodology is identical, unless adjustments are made with respect to conditions that existed in the labor market during the period of analysis.

The unemployment elasticities for the 1972 RMS model and the accompanying 90 percent and 95 percent confidence intervals are presented in Table 15. Although 24 cases are presented in Table 7, only four cases are shown in Table 15 because these are the most comparable with the cases run in the state models. The volunteer categories are of a finer grain, e.g., 17-18, I-II vs 17-18 in the RMS model. Although a recruiter variable is included in this model, the results are compatible with those obtained for the 1972 state models. That is, the unemployment elasticities are greater for 17-18 year olds than 19-21 year olds, and greater for Category I-II than Category I-III. High school and non-high school variables were not included in the model. The range in the unemployment elasticity is greater in the RMS model, i.e., .116 to .508, but this can be explained by the fact that the upper limit is a combination of the most responsive variables, 17-18 year olds and Category I-II.

Analysis of Recruiter Elasticities. The data were not available to incorporate a recruiter variable in the 1972 state models and, therefore, only the results of the 1973 state models are reported. Table 16 summarizes the elasticities for the 1973 state models with a recruiter variable. The results which were obtained for the absolute elasticities do not appear to be completely consistent with the expected behavioral hypothesis of volunteers. For example, the recruiter variable showed a positive and significant elasticity (.283) for high school graduates, but showed a negative and significant elasticity for non-high school graduates. Also, a negative elasticity (but not significant) was obtained for 19-21 year olds. However, the relative elasticities did appear consistent in that the elasticity for 17-18 year olds was more positive, i.e., did not enter the regression, than for 19-21 year olds; Category I-II was significantly larger than Category I-III; and the elasticity of high school graduate variable was larger than that for the non-high school graduate.

Table 15
ARMY UNEMPLOYMENT ELASTICITIES - 1972 RMS MODEL^a

Volunteer category	Unemployment elasticity	90% CI	95% CI
17-18, I-II/QMA	.508**	.043 to .968	-.054 to 1.065
17-18, I-III/QMA	.314	-.101 to .730	-.185 to .814
19-21, I-II/QMA	.261	-.100 to .619	-.172 to .694
19-21, I-III/QMA	.116	-.243 to .475	-.316 to .549

^aAs indicated in Table 7, 24 cases were run of which 12 were log-linear models and 12 were models using MA (as opposed to QMA) data. Also, not all runs included the high school to college ratio variable and the military population density variable. The cases that are reported in the table are for the linear models using QMA data.

Table 16
ARMY RECRUITER ELASTICITIES - 1973 STATE MODEL

Volunteer category	Unemployment elasticity	90% CI	95% CI
17-18	-	-	-
19-21	-.294	-.802 to .213	-.903 to .315
I-II	.555***	.175 to .935	.099 to 1.011
I-III	-	-	-
High school	.283*	-.078 to .645	-.150 to .717
Non-high school	-.502*	-1.091 to .088	-1.209 to .206

* Significant at the 68 percent confidence level.

*** Significant at the 95 percent confidence level.

The inconsistencies in the absolute elasticities may be explained in part by the shortcomings in the recruiter data which were available for the Army. The Army collects recruiter data on the basis of RMS boundaries only, and since RMS boundaries cross state boundaries and vice versa it is not possible to obtain an accurate count of recruiters by state. As mentioned previously, an algorithm was developed that allocated recruiters to states on the basis of ZIP codes, and it is possible that errors in the allocation process could be the cause for the observed negative recruiter elasticities. For this reason, the recruiter elasticities derived from the 1973 state models should be interpreted with extreme caution.

The results of the 1972 RMS model are presented in Table 17. The recruiter data for this model are reliable and the observed elasticities are likely to be a better representation of the true elasticities than those found with the state model. A significant difference in recruiter elasticity did exist by age for Category I-II, but there did not appear to be a difference by age for Category I-III. Also, the elasticities for the Category I-II groups were significant at the 90 percent confidence level, whereas the elasticities were significant at the 68 percent confidence level for the Category I-III groups. The 90 percent and 95 percent confidence intervals were not available for the RMS model.

Table 17
ARMY RECRUITER ELASTICITIES - RMS MODEL

Volunteer category	Recruiter elasticity
17-18, I-II/QMA	1.388 ^{**}
17-18, I-III/QMA	.790 [*]
19-21, I-II/QMA	1.369 ^{**}
19-21, I-III/QMA	.337 [*]

Other Variables in the Regression Model. The other variables included in both the RMS model and the state model were the ratio of military pay to civilian pay, the ratio of male high school graduates to male college enrollments, and the ratio of military population to civilian

population. The results are summarized in Tables 7, 8, and 9 and the following observations can be made for these variables.

Relative Pay:^{*}

1. The elasticities were positive and significant for both 1972 and 1973.
2. The elasticities were significantly greater for 1973 (significant at the 87 percent confidence level).
3. The elasticities were consistently greater for Category I-III than Category I-II.
4. The elasticities were consistently greater for 19-21 year olds than 17-18 year olds.
5. The elasticities were consistently greater for non-high school graduates than high school graduates.

High School to College Ratio:

1. The elasticities were positive and significant for both 1972 and 1973.
2. The elasticities were significantly greater for 1973 (significant at the 87 percent confidence level).
3. The elasticities were not consistently different between the age groups.
4. The elasticities were consistently greater for Category I-II than Category I-III.
5. The elasticities were consistently greater for high school graduates than for non-high school graduates. This result is expected and the non-high school graduate variable either did not come into the regression or was not significant.

Military Population Density:

1. The elasticities were positive and significant for both 1972 and 1973.
2. The elasticities were significantly greater for 1973 (significant at the 87 percent confidence level).
3. The elasticities were consistently higher for 19-21 year olds than 17-18 year olds.

* This topic is discussed in more detail in the Section Interpretation of Results - Problems and Pitfalls.

4. The elasticities were consistently higher for Category I-III than Category I-II.

5. The elasticities were consistently higher for non-high school graduates than high school graduates.

Comparison between 1972 and 1973. The analysis indicates a significant upward shift in the elasticities for pay, high school graduate ratio, and military population density from 1972 to 1973. The data were not adequate to assess the shift in the recruiter variable, and a significant downward shift was detected in the unemployment variable. The observed upward shift in the pay variable and downward shift in the unemployment variable may be explained in part by the fact that labor markets were tight and unemployment was much lower in 1973 than 1972. Also, military pay was brought more in line with its civilian counterpart as military pay had a slightly larger increase than civilian pay. The upward shift in the high school ratio may be explained by the fact that in 1973 a drop in college enrollments occurred and the direct American involvement in Vietnam ended. The shift in importance in the military population density also may be partially attributed to the ending of the Vietnam War and an improvement in the public's attitude toward the volunteer Service concept.

Air Force

The state model with variables for military pay, unemployment, high school to college graduate ratio, military population density, and recruiter strength was used to analyze volunteer enlistments for the Air Force in 1972 and 1973. The overall results of this model are summarized in Table 4.

Analysis of Unemployment Elasticities. The unemployment elasticities for the Air Force model and the accompanying 90 percent and 95 percent confidence intervals are presented in Table 18. The results are given for both 1972 and 1973. The following conclusions were drawn from the analysis.

1. Unemployment did not have a significant impact on volunteer accessions in 1972.

2. Unemployment did have a significant impact on volunteer accessions in 1973.

Table 18
AIR FORCE - UNEMPLOYMENT ELASTICITIES

Volunteer category	Unemployment elasticity	90% CI	95% CI
<u>1972</u>			
17-18	-.116*	-.258 to .025	-.288 to .054
19-21	-	-	-
I-II	-	-	-
I-III	-.047	-.200 to .106	-.230 to .137
High school	-	-	-
Non-high school	-.249*	-.504 to .007	-.552 to .061
<u>1973</u>			
17-18	-	-	-
19-21	.245***	.062 to .429	.023 to .466
I-II	.239*	-.002 to .479	-.051 to .527
I-III	.146**	-.008 to .284	-.020 to .312
High school	.171**	.022 to .322	-.008 to .351
Non-high school	-.074	-.289 to .147	-.335 to .187

- * Significant at the 68 percent confidence level.
 ** Significant at the 90 percent confidence level.
 *** Significant at the 95 percent confidence level.

3. The unemployment elasticities were consistently higher for 19-21 year olds than 17-18 year olds.

4. The unemployment elasticities were consistently higher for Category I-II than Category I-III.

5. The unemployment elasticities were consistently higher for high school graduates than for non-high school graduates.

The non-significance or negative impact of the unemployment variable in 1972 is in sharp contrast to the hypothesis that joining the Service is an attractive alternative to unemployment. The apparent lack of significance can be explained in part by the fact that the Air Force has not had difficulty in meeting its recruiting requirements and in effect queues have built up for entrance into this Service. If this hypothesis is accepted, then real changes in unemployment would have the impact of lengthening or shortening the queue and volunteer rates would not be affected until the queues diminished. Thus, observed changes in unemployment rates would not appear as significant in the regression models under these conditions.

The shift in significance in unemployment in 1973 may be explained in part by the fact that many of the volunteers in 1972 were still draft motivated, whereas in 1973 they were purely volunteers. The result is that the Air Force demand for volunteers was less in 1972 and queues existed. However, in 1973 the Air Force demand for volunteers increased so that queues might have disappeared in certain areas, and unemployment was measured as significant even though unemployment rates dropped from 1972 to 1973. The fact that the elasticities for Category I-II are higher than Category I-III and are higher for high school graduates than non-high school graduates is consistent with this logic.

Analysis of Recruiter Elasticities. The recruiter elasticities for the Air Force model and the accompanying 90 percent and 95 percent confidence intervals are presented in Table 19. The results are given for both 1972 and 1973. The following conclusions were drawn from this analysis.

1. The recruiter elasticity was positive and significant in all cases for both 1972 and 1973.

Table 19
AIR FORCE - RECRUITER ELASTICITIES

Volunteer category	Recruiter elasticity	90% CI	95% CI
<u>1972</u>			
17-18	.899**	.706 to 1.091	.667 to 1.130
19-21	.885**	.642 to 1.128	.594 to 1.176
I-II	.404**	.043 to .766	-.029 to .838
I-III	.825***	.625 to 1.024	.585 to 1.064
High school	.841***	.780 to 1.450	.713 to 1.517
Non-high school	1.115***	.657 to 1.026	.620 to 1.063
<u>1973</u>			
17-18	.901***	.674 to 1.127	.629 to 1.173
19-21	.606***	.298 to .914	.236 to .976
I-II	.492***	.096 to .888	.016 to .968
I-III	.750***	.522 to .978	.477 to 1.024
High school	.686***	.440 to .933	.391 to .982
Non-high school	1.106***	.743 to 1.469	.670 to 1.542

** Significant at the 90 percent confidence level.

*** Significant at the 95 percent confidence level.

2. There was no difference in recruiter elasticity between 1972 and 1973.

3. There was no difference in recruiter elasticity by age in 1972.

4. The recruiter elasticity was higher for 17-18 year olds than 19-21 year olds in 1973.

5. The recruiter elasticities were consistently higher for Category I-III than Category I-II.

6. The recruiter elasticities were consistently higher for non-high school graduates than high school graduates.

The Air Force recruiter variable was significant at the 95 percent confidence level in all cases except 1972 Category I-II which was significant at the 90 percent confidence level. The elasticity ranged from .404 for 1972 Category I-II to 1.115 for 1972 non-high school graduates. The average elasticity for all categories in 1972 was .828 and the average in 1973 was .757 which was only slightly lower than the previous year. This decline in elasticity may be explained by the fact that the Air Force recruiting strength was about one-third less in 1973 than 1972 even though the number of volunteer enlistments remained the same, i.e., $\epsilon = (\partial Y / \partial X) (\bar{X} / \bar{Y})$ where \bar{X} / \bar{Y} declines by one-third.

Other Variables in the Regression Model. The other variables included in the model were the ratio of military pay to civilian pay, the ratio of male high school graduates to male college enrollments, and the ratio of military population to civilian population. The results are summarized in Table 4, and the following observations are made for these variables.

Relative Pay:*

1. The pay elasticity was not significant for 1972.

2. The pay elasticity was not significant for 1973.

3. The pay elasticity was slightly higher for 1973.

4. Category I-II had a negative elasticity for both 1972 and 1973.

High School to College Ratio:

1. The elasticities were positive and significant for both 1972 and 1973.

* This topic is discussed in more detail in the Section Interpretation of Results - Problems and Pitfalls.

2. The elasticity was significantly greater for 1973 (significant at the 75 percent confidence level).

3. The elasticities for 19-21 year olds were greater than the elasticities for 17-18 year olds in 1972, but there was no difference between the two in 1973.

4. The elasticities were not consistently different between mental categories.

5. As expected, the elasticities were consistently greater for high school graduates than for non-high school graduates.

Military Population Density:

1. The elasticities were negative and significant in 1972. The implication is that the presence of a military population tends to favor the other Services.

2. The elasticity was significantly greater in 1973 with 19-21 year olds and non-high school graduates having positive elasticities (significant at the 84 percent confidence level).

3. The elasticities were consistently higher for 19-21 year olds than 17-18 year olds.

4. The elasticities were slightly higher for Category I-III than Category I-II.

5. The elasticities were consistently higher for the non-high school graduates than the high school graduates.

Comparison between 1972 and 1973. The analysis indicates a significant upward shift in the elasticities for pay, unemployment, high school graduate ratio, and the military population density from 1972 to 1973. There was no significant difference in the recruiter elasticity between 1972 and 1973. The upward shift in the pay variable may be partly explained by the fact that military pay increased relative to civilian pay in 1973.

Unemployment rates dropped substantially from 1972 to 1973 and under normal conditions where supply is the limiting factor a decline in the unemployment elasticity would be expected. However, it appears that demand was the limiting factor, i.e., queues existed, in 1972 and the transition to a purely volunteer atmosphere in 1973, where supply was the limiting factor, produced a result indicating unemployment not

correlated with volunteer accessions in 1972 and positively correlated (significant) in 1973.

The upward shift in the high school ratio variable may be explained by the drop in college enrollments in 1973 and the end of the direct American involvement in Vietnam. The shift in importance in the military population density also may be partially attributed to the ending of the Vietnam War and an improvement in the public's attitude toward the volunteer Service concept.

Marine Corps

The state model with variables for military pay, unemployment, high school to college graduate ratio, military population density, and recruiter strength was used to analyze volunteer enlistments for the Marine Corps in 1972 and 1973. The overall results of the model are summarized in Table 5.

Analysis of Unemployment Elasticities. The unemployment elasticities for the Marine Corps model and the accompanying 90 percent and 95 percent confidence intervals are presented in Table 20. It is to be noted that 10 of the pay elasticities for the Marine Corps were negative and six of the 10 were significant (see Table 5).^{*} Since the pay variable is negatively correlated with unemployment, the regression runs were made without the pay variable to observe what the impact of unemployment would be without the direct influence of the pay variable in the model. The unemployment elasticities with the pay variable excluded are given in Table 21.

The following conclusions were drawn from the analysis:

1. The unemployment elasticities were slightly higher when the pay variable was omitted from the model.
2. The unemployment elasticities were not significant with or without the pay variable in the model.
3. The unemployment elasticities were slightly higher for 19-21 year olds than 17-18 year olds.

^{*}This result is in general conflict with the hypothesis that pay and volunteers are positively correlated. The reliability of the pay data is discussed in the Section Interpretation of Results - Problems and Pitfalls and it is noted that the inclusion of the pay variable in the cross-sectional model may be questionable.

Table 20
MARINE CORPS - UNEMPLOYMENT ELASTICITIES

Volunteer category	Unemployment elasticity	90% CI	95% CI
<u>1972</u>			
17-18	-	-	-

I-III	-.081	-.250 to .086	-.284 to .120
High school	-.056	-.262 to .152	-.305 to .195
Non-high school	-.075	-.327 to .181	-.378 to .232

* Significant at the 68 percent confidence level.

Table 21

MARINE CORPS - UNEMPLOYMENT ELASTICITIES - NO PAY VARIABLE IN MODEL^a

Volunteer category	Unemployment elasticity	Old R ²	New R ²
<u>1972</u>			
17-18	.058	.332	.302
19-21	.068	.169	.162
I-II	-	.263	.115
I-III	-	.215	.095
High school	.114	.071	.071
Non-high school	.066	.285	.281
<u>1973</u>			
17-18	-.065	.310	.227
19-21	-	.301	.296
I-II	-.095	.171	.036
I-III	-	.298	.221
High school	-	.139	.123
Non-high school	-	.248	.201

^aThe "Old" R² refers to the value obtained with the pay variable in the model and "New" R² refers to the value obtained without the pay variable in the model.

4. The unemployment variable for Category I-II and Category I-III did not enter the regression model in either case, with or without the pay variable.

5. The unemployment elasticities were slightly higher for high school graduates than non-high school graduates.

6. The unemployment elasticities were slightly lower in 1973 than 1972.

An examination of the old and new values for R^2 listed in Table 21 reveals that the pay variable does not contribute substantially to the explanation of the total variation in the dependent variable, i.e., volunteers, except in the cases of Category I-II and Category I-III. Since the unemployment variable does not enter the regression model in either situation, with or without the pay variable, the pay variable does not have a significant impact on the value of the unemployment elasticity.

The argument that the Marine Corps volunteer program was demand limited, i.e., queues existed, cannot be used to explain the non-significance of unemployment on volunteer accessions because in both 1972 and 1973 the Marine Corps was short of the desired objective of 55 percent high school graduates.* Although the largest elasticity was obtained for the high school group, the elasticity was not significant at a 68 percent confidence level in either 1972 or 1973.

A more tenable explanation is that the Marine Corps maintains a reputation for discipline, a high level of physical fitness and a close association with combat readiness, and this image may be such that a certain type of volunteer is attracted independent of the rate of unemployment. That is, the type of individual that joins the Marine Corps does so as a first choice, and does not select this Service as an alternative to unemployment.

Analysis of Recruiter Elasticities. The recruiter elasticities for the Marine Corps model and the accompanying 90 percent and 95 percent confidence intervals are presented in Table 22. The results for the

* In 1972 high school graduates constituted approximately 41.5 percent of the total; in 1973, approximately 40.8 percent.

* Significant at the 68 percent confidence level.

** Significant at the 90 percent confidence level.

*** Significant at the 95 percent confidence level.

recruiter elasticities when the pay variable was omitted are given in Table 23. The results are given for both 1972 and 1973 and the following conclusions were drawn from the analysis:

1. The recruiter elasticities were positive and significant in all cases for both 1972 and 1973.
2. The omission of the pay variable from the model had little or no impact on the value of the recruiter elasticity.
3. The recruiter elasticities were slightly higher for 1972 than 1973.
4. The recruiter elasticities were consistently higher for 17-18 year olds than 19-21 year olds.
5. The recruiter elasticities were consistently higher for Category I-III than Category I-II with the pay variable in the model. Omitting the pay variable reversed this order of significance for 1972.
6. In 1972 the recruiter elasticities were significantly higher for non-high school graduates than high school graduates.
7. There was no significant difference between the recruiter elasticities for 1972 and 1973.

The Marine Corps recruiter variable was significant at the 90 or 95 percent level in 18 out of the 24 cases. It was significant at the 68 percent confidence level in five of the remaining cases. The only case where the recruiter elasticity was not significant was 1973 Category I-II in the model without the pay variable. The values for the recruiter elasticities in the model with the pay variable ranged from .115 for 1973 Category I-II to .438 for 1972 non-high school graduates. The average for all volunteer categories was .300 for 1972 and .232 for 1973.

The values for the recruiter elasticities in the model without the pay elasticity ranged from .073 for 1973 Category I-II to .456 for 1972 non-high school graduates. The average for all volunteer categories was .332 for 1972 and .209 for 1973.

Other Variables in the Regression Model. The other variables included in the model were the ratio of military pay to civilian pay, the ratio of male high school graduates to male college enrollments, and the ratio of military population to civilian population. The results are summarized in Table 5. Also, the model was run without the pay variable. The results of this model are summarized in Table 24. The following observations are made for the other variables.

Table 23

Table 24
MARINE CORPS ELASTICITIES OF OTHER VARIABLES
WHEN THE PAY VARIABLE IS OMITTED

Volunteer category	1972		1973	
	High school/ college	Military population	High school/ college	Military population
17-18	-	-	.168 [*]	-.035
19-21	.222 ^{***}	.091 ^{***}	.187 [*]	.050 [*]
I-II	.121	-	.310 ^{**}	-.035
I-III	-	-	.195 [*]	-
High school	.156 [*]	.041	.285 ^{**}	-
Non-high school	-	-	-	-

Relative Pay:

1. The pay elasticities were negative for all volunteer categories for 1972 except high school graduates where the pay variable did not enter the regression model.

2. The pay elasticities were negative for all cases for 1973.

3. The pay elasticities were significant in three out of six cases for 1972 and four out of six cases for 1973.

4. The pay elasticities were consistently higher for 19-21 year olds than 17-18 year olds.

5. The pay elasticities were consistently higher for Category I-III than Category I-II.

6. The pay elasticities were consistently higher for high school graduates than non-high school graduates.

High School to College Ratio:

1. The elasticity was positive and significant in only one case for 1972, Category I-II. All other cases were not significant.

2. The elasticity was positive in all cases for 1973 and significant in four out of six cases.

3. The elasticities were significantly greater for 1973 than 1972 (significant at the 75 percent confidence level).

4. The elasticities were not different between age groups.

5. The elasticities were consistently higher for Category I-II than for Category I-III.

6. The elasticity was higher for high school graduates than non-high school graduates in 1972, but strangely the elasticity was lower for high school graduates than non-high school graduates in 1973. When the pay variable was omitted from the model, the elasticity was uniformly higher for high school graduates than non-high school graduates.

Military Population Density:

1. The elasticities were positive in all cases for 1972 and 1973, and significant in all but two cases for both years.

2. The elasticities were significantly greater for 1973 than 1972 (significant at the 75 percent confidence level).

3. The elasticities were consistently higher for 19-21 year olds than 17-18 year olds.

4. There was no difference in elasticities between Category I-II and Category I-III.

5. The elasticities were consistently higher for the non-high school graduates than the high school graduates for the model with the pay variable. When the pay variable was omitted, the variable did not enter the regression in 1973 for either high school or non-high school graduates and it entered at the non-significant level for high school graduates in 1972.

Comparison between 1972 and 1973. The analysis indicates a significant upward shift in the elasticities for the high school graduate ratio and the military population density from 1972 to 1973. There was a slight decline in the elasticities for pay, unemployment, and recruiters.

The upward shift in the high school ratio variable may be explained by the drop in college enrollments in 1973 and the end of the direct American involvement in Vietnam. The shift in importance in the military population density also may be partially attributed to the ending of the Vietnam War and an improvement in the public's attitude toward the volunteer Service concept.

The decline in the unemployment elasticity may be attributed to the decline in unemployment rates from 1972 to 1973. The decline in the pay variable is not significant and the observed difference may be due to

regional differences in volunteer propensity to enlist rather than differences in pay. Despite the fact that the Marine Corps increased the average recruiter force from 1972 to 1973 by about 15 percent, the recruiter elasticity declined slightly. The drop may be partially attributed to the increased attractiveness of the other Services in terms of the volunteers' perceived opportunities for training and skill development.

Navy

The state model with variables for military pay, unemployment, high school to college graduates ratio, military population density, and recruiter strength was used to analyze volunteer enlistments for the Navy in 1972 and 1973. The overall results of the model are summarized in Table 6.

Analysis of Unemployment Elasticities. The unemployment elasticities for the Navy model and the accompanying 90 percent and 95 percent confidence intervals are presented in Table 25. Nine of the pay elasticities for the Navy were negative and six of the nine were significant at the 68 percent confidence level. As in the case of the Marine Corps, the model was rerun without the pay variable. These results are provided in Table 26.

The following conclusions were drawn from the analysis:

1. In 1972 the unemployment elasticities were significantly higher when the pay variable was omitted.
2. In 1973 the unemployment elasticities were slightly higher when the pay variable was omitted.
3. The unemployment elasticities were generally not significant when the pay variable was in the model. When the pay variable was omitted, the elasticities became significant.
4. The unemployment elasticities were significantly higher for 19-21 year olds than 17-18 year olds.
5. When the pay variable was in the model, there was no difference in the unemployment elasticity between Category I-II and Category I-III.
6. When the pay variable was omitted, the unemployment elasticity was consistently higher for Category I-II than Category I-III.
7. The unemployment elasticities were significantly higher for high school graduates than for non-high school graduates.

*** Significant at the 95 percent confidence level.

8. The unemployment variable did not enter the regression model for non-high school graduates in 1972. The unemployment elasticity was negative and significant in 1973.

9. When the pay variable was in the model, the unemployment elasticities were not significantly different between 1972 and 1973.

10. When the pay variable was omitted from the model, the unemployment elasticity was significantly higher in 1972 than 1973 (significant at the 90 percent confidence level).

If the pay variable is included in the model, the conclusion is that unemployment is not a significant variable in determining the level of Navy volunteers. On the other hand, if the pay variable is excluded, just the opposite conclusion is reached. The differences may be explained by the intercorrelation existing between the unemployment variable and the pay variable. The pay variable has an obvious downward bias on the value of the unemployment elasticity. While the difference may be explained statistically, it does not provide a satisfactory explanation for this observed relationship.

An hypothesis that is suggested is that the pay variable may not be a true reflection of differentials in real income,^{*} but rather is more a reflection of regional differentials in the propensity to enlist. The pay variable is defined as the ratio of military pay to civilian pay and since the military pay is the same throughout the only differences are observed differences in civilian pay from state to state, and the regression results may be indicative of state or locational differences rather than differences in income since income differs regionally and by state. This can be used to explain the observed negative correlation between the pay variable and volunteer rates. Thus, it would appear that unemployment elasticities without the pay variable would be the better of the two hypotheses.

In the last two years, the Navy has had little difficulty in obtaining the recruits it needs, and for the lower mental categories and non-high school graduates queues exist and the observed elasticities are lower as seen in both models, with and without the pay variables.

* The validity of the pay variable is discussed in the Section Interpretation of Results - Problems and Pitfalls.

Analysis of Recruiter Elasticities. The recruiter elasticities for the Navy model and the accompanying 90 percent and 95 percent confidence intervals are presented in Table 27. The results for the recruiter elasticities when the pay variable was omitted are given in Table 28. The results are given for both 1972 and 1973 and the following conclusions were drawn from the analysis:

1. The recruiter elasticity was positive and significant in every case in 1972 and 1973 except for non-high school graduates.

2. The recruiter elasticity was negative for non-high school graduates in each case. It was significant at the 68 percent confidence level in three out of the four cases.

3. The recruiter elasticities were slightly higher for 1972 than 1973.

4. The recruiter elasticities were consistently higher for 19-21 year olds than 17-18 year olds.

5. The recruiter elasticities were consistently higher for Category I-II than Category I-III.

6. The recruiter elasticities were significantly higher for high school graduates than non-high school graduates.

The Navy recruiter variable was positive and significant at the 95 percent confidence level in all cases except non-high school graduates where it was negative and significant at the 68 percent confidence level. This discrepancy may be explained as follows. The Navy maintained a high level of recruiters in the field in both years (2932 in 1972, 2902 in 1973), and the primary emphasis was on recruiting the high school graduate. In both years the Navy managed to recruit better than 70 percent high school graduates and substantial queues existed for the non-high school graduates. As a result, in the areas that had the heaviest concentrations of recruiters, the non-high school graduates were actually turned away in substantial numbers. This accounts for the fact that there is an observed negative correlation between recruiter strength and non-high school graduate volunteers. If the quotas had not existed and all qualified non-high school applicants were accepted, the elasticity undoubtedly would have been positive.

The values for the recruiter elasticities (excluding non-high school graduates) in the model with the pay variable ranged from .361 for 1973

Table 27

*** Significant at the 95 percent confidence level.

17-18 year olds to 1.182 for 1972 Category I-II. The average recruiter elasticity (excluding the non-high school graduate) for 1972 was .702 and the average for 1973 was .54.

The values for the recruiter elasticity (excluding the non-high school graduate) in the model without the pay elasticity ranged from .336 for 1972 17-18 year olds to 1.031 for 1972 Category I-II. The average recruiter elasticity (excluding the non-high school graduate) for 1972 was .629 and the average for 1973 was .553.

Other Variables in the Regression Model. The other variables included in the model were the ratio of military pay to civilian pay, the ratio of male high school graduates to male college enrollments, and the ratio of military population to civilian population. The results are summarized in Table 6. Also, the model was run without the pay variable. The results of this model are summarized in Table 29. The following observations are made for the other variables:

Relative Pay:

1. The pay elasticities were negative for all volunteer categories for both 1972 and 1973 except non-high school graduates where the pay variable was positive and significant at the 68 percent confidence level for both years.

2. All the negative pay elasticities were significant at the 68 percent confidence level except 1972 Category I-III and 1972 high school graduates which were not significant.

3. The pay elasticities were consistently higher (less negative) for 19-21 year olds than 17-18 year olds.

4. The pay elasticities were consistently higher for Category I-III than Category I-II.

5. The pay elasticities were consistently higher for non-high school graduates than high school graduates.

6. The pay elasticities were significantly higher (less negative) for 1973 than 1972 (significant at the 84 percent confidence level).

High School to College Ratio:

1. When the pay variable was included in the model, the elasticities were positive in all cases except non-high school graduates for 1972 and

Table 29

* Significant at the 68 percent confidence level.

** Significant at the 90 percent confidence level.

1973. The elasticity was significant for 19-21 year olds, Category I-II, and high school graduates at the 95 percent confidence level for both 1972 and 1973.

2. When the pay variable was omitted from the model the elasticities were all positive except the variables for 1972 17-18 year olds, 1972 Category I-III, 1972 non-high school graduates, and 1973 non-high school graduates did not enter the regression.

3. The elasticities were consistently less when the pay variable was omitted.

4. The elasticities were significantly higher for 1973 than 1972 (significant at the 90 percent confidence level).

5. The elasticities were consistently higher for 19-21 year olds than 17-18 year olds.

6. The elasticities were consistently higher for Category I-II than Category I-III.

7. The elasticities were consistently higher for high school graduates than non-high school graduates.

Military Population Ratio:

1. The elasticities were generally small and not significant for both 1972 and 1973.

2. The elasticity was significant for 19-21 year olds in all cases.

3. There were no significant differences in elasticities between 1972 and 1973.

4. The elasticities were consistently higher for 19-21 year olds than 17-18 year olds.

5. There was no difference in the elasticities for Category I-II and Category I-III.

6. The elasticities were slightly higher for high school graduates than non-high school graduates.

Comparison between 1972 and 1973. The analysis indicates a significant upward shift in the elasticities for the high school graduate ratio and a slight upward shift for the pay elasticities and the recruiter elasticities from 1972 to 1973. There was a slight decline in the unemployment elasticities from 1972 to 1973, and the elasticities for military population density were unchanged.

The upward shift in the high school ratio variable can be explained by the drop in 1973 college enrollments and the ending of the Vietnam War. The increase in recruiter elasticity may be attributed to the relative increase in recruiter strength to volunteers. That is, the number of recruiters remained about the same in 1973 but the number of recruits declined, i.e., \bar{X}/\bar{Y} increased and thus $(\partial Y/\partial X)(\bar{X}/\bar{Y}) = \epsilon$ increased.

The relative increase in the pay elasticities and the downward shift in the unemployment elasticities may be attributed to the fact that unemployment rates were lower in 1973 and that military pay was brought more in line with its civilian counterpart in 1973.

DOD Total

Since DOD total is comprised of the sum of the volunteers for the four Services, the elasticities for DOD total will be influenced by the relative importance of each Service. For example, in 1972 about 42 percent of the volunteers were for the Army, 18 percent for the Air Force, 14 percent for the Marine Corps, and 26 percent for the Navy.

Analysis of Unemployment Rates. The unemployment elasticities for the two versions of the state model for DOD total and the accompanying 90 percent and 95 percent confidence intervals are presented in Table 30. The following conclusions were drawn from the analysis.

1. The elasticities were positive and significant in all cases for the 1972 model without the recruiter variable except non-high school graduates. The non-high school graduate elasticity was .106 and not significant.
2. Comparing the 1972 and 1973 models without the recruiter variable, the elasticities were significantly higher in 1972 (significant at the 75 percent confidence level).
3. Comparing the 1973 models with and without the recruiter variable, the elasticities for the model without the recruiter variable were slightly higher than when the recruiter variable is included. Two of the categories (I-II and high school graduates) were significant in the model without recruiters whereas only one category (high school graduates) was significant in the model with the recruiter variable.
4. Overall there was no difference in elasticity between age groups.

Table 30
DOD UNEMPLOYMENT ELASTICITIES

Volunteer category	Unemployment elasticity	90%CI	95% CI
<u>1972 without Recruiters</u>			
17-18	.144**	.000 to .287	-.028 to .316
19-21	.143*	-.027 to .313	-.061 to .347
I-II	.242*	-.022 to .507	-.075 to .559
I-III	.182***	.045 to .319	.017 to .347
High school	.204***	.048 to .360	.017 to .392
Non-high school	.106	-.126 to .337	-.172 to .384
<u>1973 without Recruiters</u>			
17-18	.039	-.087 to .164	-.111 to .185
19-21	-	-	-
I-II	.160*	-.020 to .340	-.056 to .376
I-III	.064	-.050 to .178	-.073 to .201
High school	.141**	.011 to .272	-.015 to .298
Non-high school	-.092	-.310 to .126	-.354 to .169
<u>1973 with Recruiters</u>			
17-18	-	-	-
19-21	-	-	-
I-II	.106	-.075 to .288	-.111 to .324
I-III	.044	-.069 to .158	-.092 to .180
High school	.111*	-.015 to .236	-.040 to .262
Non-high school	-.092	-.310 to .126	-.354 to .169

* Significant at the 68 percent confidence level.

** Significant at the 90 percent confidence level.

*** Significant at the 95 percent confidence level.

5. The elasticities for Category I-II were consistently higher than Category I-III.

6. The elasticities for high school graduates were consistently higher than non-high school graduates.

7. The elasticity for non-high school graduates was negative in both cases for 1973, but not significantly different from zero.

8. Overall, Category I-II and high school graduates have the highest unemployment elasticities.

The results in the analysis for the 1972 models are consistent with the finding of Bennett, Haber and Kinn that the omission of the recruiter variable causes an upward bias in the unemployment elasticity. Data were not available to test the hypothesis for 1972 but an approximation of the elasticities for 1972 with the recruiter variable may be made by extrapolation from the average biases for 1973. By examining the two variables (Category I-II and high school graduates) that were significant in 1973, it can be seen that the average bias is about 27 percent. That is, the unemployment elasticity with the recruiter variable was approximately 73 percent of the elasticity without the recruiter variable.

Applying this percentage to the 1972 unemployment elasticities without the recruiter variable gives the following projections:

<u>Volunteer category</u>	<u>Projected elasticity for 1972</u>
17-18	.105
19-21	.104
I-II	.177
I-III	.133
High school	.149
Non-high school	.077

While it is not possible to make specific assertions regarding the significance of these projections, it can be concluded that the overall unemployment elasticity for DOD total in 1972 was greater than .1 and less than .2.

Analysis of Recruiter Elasticities. Reliable recruiter data were not available on a cross-sectional basis by state for DOD total for 1972 and, therefore, only the 1973 model could be run. The recruiter elasticities for the 1973 DOD total model and the accompanying 90 percent and 95

percent confidence intervals are presented in Table 31. The following conclusions were drawn from the analysis.

1. The recruiter elasticities were positive for all cases except non-high school graduates. Non-high school graduates did not enter the regression.

2. The elasticities for 17-18 year olds and Category I-III were significant at the 90 percent confidence level, and they were significant at the 95 percent confidence level for Category I-II and high school graduates. The elasticity for 19-21 year olds was not significant.

3. The elasticity was higher for 17-18 year olds than 19-21 year olds.

4. The elasticity was higher for Category I-II than Category I-III.

5. The elasticity was higher for high school graduates than non-high school graduates.

Excluding the non-high school graduate category, the overall recruiter elasticity for 1973 for DOD total was .342. The elasticities ranged from .140 for 19-21 year olds to .557 for Category I-II. The non-significance for the non-high school graduate variable can be explained by the fact that negative elasticities were obtained for this category for both the Army and the Navy, and together these Services accounted for 69 percent of the total non-high school graduates in 1973. The same argument applies to the low value observed for the 19-21 year olds in that the Army and Navy accounted for 64 percent of the volunteers in this category.

If it can be assumed that DOD recruiter policy is manifested through the recruiters in the field, then the interpretation of the recruiter elasticities is that the policy to upgrade the quality of the Services by recruiting high school graduates and the higher mental categories was effective for 1973 in terms of recruiter emphasis. Also, it appears that there was an emphasis during this time to recruit from the lower age group rather than the higher age group.

Other Variables in the Regression Model. The other variables included in both the models with and without the recruiter variable were the ratio of military pay to civilian pay, the ratio of male high school graduates to male college enrollments, and the ratio of military population

Table 31

DOD RECRUITER ELASTICITIES

Volunteer Category	Recruiter elasticity	90% CI	95% CI
<u>1973 with Recruiters</u>			
17-18	.335**	.056 to .756	-.014 to .826
19-21	.140	-.217 to .498	-.289 to .569
I-II	.557***	.140 to .974	.057 to 1.057
I-III	.265**	.004 to .527	-.048 to .579
High school	.413***	.125 to .700	.068 to .758
Non-high school	-	-	-

** Significant at the 90 percent confidence level.

*** Significant at the 95 percent confidence level.

to civilian population. The results are summarized in Tables 10 and 11. The following observations are made for the other variables.

Relative Pay:

1. In the model without the recruiter variable, the elasticities were mixed for 1972. The pay variable did not enter the regression for 17-18 year olds and Category I-III. The elasticity for 19-21 year olds was positive and significant at the 90 percent confidence level. The elasticities for high school graduates and non-high school graduates were positive but not significant. The elasticity for Category I-II was negative and significant at the 90 percent confidence level.

2. In the model without the recruiter, the elasticities were significantly higher for 1973 than 1972 (significant at the 90 percent confidence level). All elasticities were positive and significant for 1973 except the non-high school graduate variable did not enter the regression. The elasticity for non-high school graduates was significant at the 95 percent confidence level (.618).

3. In the 1973 model with recruiters, all elasticities were positive and significant for 1973 except the non-high school graduate variable did not enter the regression. The elasticity for non-high school graduates was significant at the 95 percent confidence level (.618).

4. The elasticities for the 1973 model without recruiters were consistently higher than the 1973 model with recruiters, i.e., the presence of the recruiter variable tends to lower the pay elasticity.

5. The elasticities for 19-21 year olds were consistently higher than for 17-18 year olds.

6. The elasticities for Category I-III were consistently higher than for Category I-II.

7. The elasticities for non-high school graduates were consistently higher than for high school graduates.

High School to College Ratio:

1. When the recruiter variable was excluded from the model, all the elasticities were positive except for non-high school graduates for 1972 and 1973. The variable for non-high school graduates did not enter the regression in either year.

2. Three of the elasticities were significant in 1972. High school graduates were significant at the 95 percent confidence level, and 19-21 year olds and Category I-II were significant at the 68 percent level.

3. In 1973, the variables for high school graduates, 17-18 year olds, and Category I-III were significant at the 95 percent confidence level. Category I-II was significant at the 90 percent confidence level and 19-21 year olds were significant at the 68 percent confidence level.

4. The elasticities were significantly higher in 1973 than 1972 (significant at the 87 percent confidence level).

5. In the 1973 model with the recruiter variable, all the elasticities were significant except non-high school graduates which did not enter the regression.

6. In the model with the recruiter variable, the elasticity was higher for 17-18 year olds than 19-21 year olds. The opposite was true for the model without the recruiter variable.

7. The elasticities were consistently higher for Category I-II than Category I-III.

8. The elasticities were consistently higher for high school graduates than non-high school graduates. The variable for non-high school graduates did not enter any of the regressions.

Military Population Ratio:

1. When the recruiter variable was excluded from the model, all the elasticities were positive except 1973 Category I-II which did not enter the regression. Three out of six of the elasticities were significant for 1972 and five out of six of the elasticities were significant in 1973.

2. The elasticities for 1973 were only slightly higher than for 1972.

3. When the recruiter variable was included in the 1973 model, the elasticities were unchanged.

4. The elasticities for 19-21 year olds were consistently higher than for 17-18 year olds.

5. The elasticities were consistently higher for Category I-III than for Category I-II.

6. The elasticities were consistently higher for non-high school graduates than for high school graduates.

Comparison between 1972 and 1973. The analysis indicates a significant upward shift from 1972 to 1973 for the elasticities for pay and the high school graduate ratio. There was only a slight upward shift in the elasticity for the military population density variable, and there was a significant downward shift in the unemployment elasticities. Reliable recruiter data were not available for DOD total for 1972 and, therefore, it was not possible to compare recruiter elasticities for the two years.

As in the case of the Army and the Navy, the observed upward shift in the elasticity of the pay variable and the downward shift in elasticity of the unemployment variable may be explained in part by the decrease in unemployment from 1972 to 1973 and the relative increase in military pay from 1972 to 1973.

The upward shift in the elasticity of the high school graduate ratio was consistent for each Service and DOD total and can be explained by the decrease in college enrollments in 1973 and the end of the direct American involvement in the Vietnam War. The small upward shift in the elasticity of the military population density variable was not significant, but the tendency for the elasticity to increase may be attributed in part to an improvement in the public's attitude toward the volunteer Service concept.

ANALYSIS OF FINDINGS - COMPARISON OF SERVICES

The analysis and findings of the regression models for each Service and DOD total were discussed in the previous section. The objectives of this section are threefold:

1. To make comparisons of the elasticities among the Services and DOD total.
2. To assess the relative importance of the variables for pay, unemployment rates, male high school graduates to male college enrollments, military population density, and recruiter strength across all Services and DOD total.
3. To determine whether shifts in elasticities across all Services and DOD total have occurred from 1972 to 1973.

This section is divided into four subsections:

1. Comparison of unemployment elasticities
2. Comparison of recruiter elasticities

3. Comparison of other elasticities

4. Summary of elasticity comparisons

In comparing the elasticities, only the results of the state models are used. The RMS models are not used because the data are not directly comparable and any observed differences in elasticities may be the result of differences in geographic boundaries rather than real differences.

Comparison of Unemployment Elasticities

Table 32 summarizes the unemployment elasticities for all Services and DOD total for 1972 and 1973. The results for 1972 Army and 1972 DOD are based on the regression runs without the recruiter variable in the model. It was noted in the previous section that the omission of the recruiter variable created only a slight upward bias in the unemployment elasticities, and the values given in Table 32 for these cases may be accepted as representative of the upper range of the true elasticities.

The average elasticities for the six volunteer categories are given for each Service and the change in the average elasticity from 1972 to 1973 is given at the bottom of the table. The average elasticity for DOD total was .170 for 1972. For 1972, the highest elasticity was for the Army (.226) and the lowest elasticity was for the Air Force (-.069). The average elasticities for the Marine Corps and the Navy were .036 and .083, respectively. Overall the unemployment elasticities were not significantly different from zero for the Air Force, Marine Corps, and the Navy. Unemployment was significant for the Army during 1972.

In order to provide a crude consistency check between DOD total and the Service components, a weighted elasticity was calculated using the percentage of volunteers for each Service.* The weighted elasticity was calculated to be .107 which is about one-third less than the projected .170 for DOD total. Part of this discrepancy may be explained by the categories for the Air Force and the Marine Corps which did not enter the regressions and were recorded in the average as zero elasticities.

* The percent of volunteers going into each Service for 1972 is as follows: Army, 41.6 percent; Air Force, 18.5 percent; Marine Corps, 14.5 percent; Navy, 25.4 percent.

$$\text{weighted elasticity} = .226(.416) - .069(.185) + .036(.145) + .083(.254)$$

Table 32
UNEMPLOYMENT ELASTICITIES

Volunteer category	Army	Air Force	Marine Corps	Navy	DOD
		<u>1972</u>			
17-18	.232 ^{**}	-.116 [*]	-	.094	.144 ^{**}
19-21	.098	-	.101	.167 [*]	.143 [*]
I-II	.340 ^{***}	-	-	-	.242 [*]
I-III	.255 ^{***}	-.047	-	.085	.182 ^{***}
High school	.230 ^{**}	-	.113	.152 [*]	.204 ^{***}
Non-high school	.198 [*]	-.249 [*]	-	-	.106
Total	1.353	-.412	.214	.498	1.021
Average	.226	-.069	.036	.083	.170
		<u>1973</u>			
17-18	.102	-	-.098 [*]	-	-
19-21	-.075	.245 ^{***}	-	.115 [*]	-
I-II	.074	.239 [*]	-.179 [*]	.118	.106
I-III	.078	.146 ^{**}	-.081	-	.044
High school	-	.171 ^{**}	-.075	.230 ^{**}	.111 [*]
Non-high school	-	-.074	-.056	-.432 ^{***}	-.092
Total	.179	.727	-.489	.031	.169
Average	.030	.121	-.082	.005	.028
Change in average from 1972	-.196	+.190	-.118	-.078	-.142

* Significant at the 68 percent confidence level.

** Significant at the 90 percent confidence level.

*** Significant at the 95 percent confidence level.

Also, part of this difference is probably due to the omission of the recruiter variable from the 1972 Army and DOD total models.

The data were consistent for all Services for the 1973 models and more reliable comparisons among Services can be made. For 1973, the average elasticity for DOD total was $-.142$. The highest average elasticity was for the Air Force ($.190$) and strangely the lowest average elasticity was for the Army ($-.196$). The Marine Corps and Navy both had negative elasticities of $-.118$ and $-.078$, respectively. Overall the elasticities were significant for the Air Force but not significant for the other Services.

Also, a weighted elasticity based on percentage of total volunteers was calculated for each Service. The weighted elasticity was calculated to be $.028$, which is exactly equal to the elasticity given for DOD total.

In examining the trend in the unemployment elasticities from 1972 to 1973 (see the bottom of Table 32), the average elasticities declined for the Army, Marine Corps, Navy and DOD total, whereas the average elasticity increased for the Air Force.

Statistical tests of significance were made comparing the unemployment elasticities for all the Services to determine if significant differences existed between the volunteer categories by age, mental category, and education. The results are given in Table 33. It was found that there was no difference between age groups, the elasticity for Category I-II was higher than Category I-III, and the elasticity for high school graduates was higher than non-high school graduates.

Table 33
TESTS OF SIGNIFICANCE - UNEMPLOYMENT ELASTICITIES
AGE, MENTAL CATEGORY AND EDUCATION

Comparison	Results
1. $H_0: 17-18 > 19-21$	No significant difference
2. $H_0: I-II > I-III$	Significant at 80 percent confidence
3. $H_0: HS > NHS$	Significant at 90 percent confidence

Comparison of Recruiter Elasticities

Table 34 summarizes the recruiter elasticities for all Services and DOD total for 1972 and 1973. Reliable data were not available for the Army and DOD total for 1972 and, therefore, only limited comparisons can be made for 1972. Data were available for 1973 for the Army and DOD total, but as indicated in the previous section, the reliability of the Army recruiter data is questionable because of the conversion algorithm that was used.

For 1972, the highest average elasticity recorded was for the Air Force with .828, the next highest was for the Navy with .549, and the Marine Corps had the lowest with .299. While it would not be a valid comparison, it should be noted that for the 1972 Army RMS model, the average recruiter elasticity was .971. If this estimate is accepted, a weighted elasticity can be constructed for DOD total. The weighted elasticity for DOD total is calculated as .739.

Recruiting data were available for the Army for 1973 and results are given in Table 34 for all Services and DOD total. The average recruiter elasticity for 1973 for DOD total was .285. The highest average elasticity was for the Air Force (.757) and the lowest average elasticity was for the Army (.007). The Navy had an average elasticity of .418 and the Marine Corps had an average elasticity of .232. The weighted elasticity for the four Services is:

$$.007(.418) + .757(.215) + .232(.142) + .418(.225) = .293$$

This compares favorably with the estimated .285 for DOD total.

In examining the trend in recruiter elasticities from 1972 to 1973 for the Air Force, Marine Corps and Navy, the average elasticities declined in each case. The decline was about 8 percent for the Air Force and 22 percent for the Navy and Marine Corps. If the 1972 Army RMS model elasticities are compared with the 1973 Army state model elasticities, an unusually large decline is noted. Most of the difference is probably due to the differences in the data rather than the elasticity shift from 1972 to 1973. If a 25 percent shift is accepted as realistic, then estimates can be made for either 1972 or 1973 based on the acceptance of the state model or the RMS. For example, forecasting 1973 on the basis of the 1972 RMS model would be:

Table 34
RECRUITER ELASTICITIES

Volunteer category	Army	Air Force	Marine Corps	Navy	DOD
		<u>1972</u>			
17-18	N	.899 ^{***}	.388 ^{***}	.372 ^{***}	N
19-21	N	.885 ^{***}	.200 [*]	.530 ^{***}	N
I-II	N	.404 ^{**}	.288 [*]	1.182 ^{***}	N
I-III	N	.825 ^{***}	.305 ^{***}	.673 ^{***}	N
High school	N	.841 ^{***}	.178 [*]	.753 ^{***}	N
Non-high school	N	1.115 ^{***}	.438 ^{***}	-.213 [*]	N
Total	N	4.969	1.797	3.297	N
Average	N	.828	.299	.549	N
		<u>1973</u>			
17-18	-	.901 ^{***}	.275 ^{***}	.361 ^{***}	.335 ^{**}
19-21	-.294	.606 ^{***}	.226 ^{***}	.458 ^{***}	.140
I-II	.555 ^{***}	.492 ^{***}	.115 [*]	.866 ^{***}	.557 ^{***}
I-III	-	.750 ^{***}	.259 ^{***}	.404 ^{***}	.265 ^{**}
High school	.283 [*]	.686 ^{***}	.265 ^{***}	.635 ^{***}	.413 ^{***}
Non-high school	-.502 [*]	1.106 ^{***}	.254 ^{***}	-.215 [*]	-
Total	.042	4.541	1.394	2.509	1.71
Average	.007	.757	.232	.418	.285
Change in average from 1972	-	-.071	-.067	-.131	-

- * Significant at the 68 percent confidence level.
 ** Significant at the 90 percent confidence level.
 *** Significant at the 95 percent confidence level.

$$(.971)(.80) = .776$$

If 1972 is forecasted on the basis of the 1973 state model, the result would be

$$(.007)(1.25) = .009$$

Clearly, there is a discrepancy between the two models which cannot be reconciled on the hypothesis that a large shift occurred in the recruiter elasticities between the two years. The implication of the state model is that the Army's recruiting program is ineffective, whereas the implication of the RMS model is that the Army's recruiting program is highly effective. The higher degree of reliability for the data for the RMS model would tend to support the latter conclusion rather than the former.

Statistical tests of significance were made comparing the recruiter elasticities for all Services to determine if significant differences existed between the volunteer categories by age, mental category and education. The results are given in Table 35.

Table 35
TESTS OF SIGNIFICANCE - RECRUITER ELASTICITIES
AGE, MENTAL CATEGORY, AND EDUCATION

Comparison	Results
1. $H_0: 17-18 > 19-21$	Significant at 95 percent confidence
2. $H_0: I-II > I-III$	Significant at 70 percent confidence
3. $H_0: HS > NHS$	Significant at 70 percent confidence

There was a significant difference in all three cases, but the level of significance was only 70 percent for mental category and education, whereas it was 95 percent for age.

Comparison of Other Elasticities

Table 36 summarizes the military pay elasticities, Table 37 summarizes the male high school graduate to male college enrollment ratio elasticities, and Table 38 summarizes the military population density elasticities. A comparison of the elasticities in each of the tables yields the following conclusions:

Table 36

Military Pay:

1. The average elasticities were highest for the Army for both 1972 and 1973 (.314 and .744).
2. The average elasticities for the Air Force were not significantly different from zero in both years (-.082 and .083).
3. The average elasticities for the Navy were negative in both years (-.626 and -.096), but the average elasticity was not significantly different from zero for 1973.
4. The average elasticities for the Marine Corps were negative in both years (-.326 and -.475).
5. The average elasticities for DOD total were positive for both years (.007 and .253), but the average for 1972 was not significantly different from zero.
6. There was an upward shift in the elasticities from 1972 to 1973 for all Services except the Marine Corps which experienced a downward shift.
7. If the pay variable is really a measure of geographic location instead of relative pay, then the Army has a high negative correlation with areas where civilian income is low, e.g., the Southeast, and the Navy has a high positive correlation with areas where civilian income is high, e.g., the Midwest.

High School to College Ratio:

1. The average elasticities were positive in all cases for 1972 and 1973.
2. The average elasticities were significant and approximately the same for the Army, Air Force and Navy for 1972 (.209, .204, and .224, respectively). The average elasticity for the Marine Corps for 1972 was not significantly different from zero (.093), and the average elasticity for DOD total was .133.
3. The average elasticities were significant for all Services for 1973. The Army, Air Force and Marine Corps experienced substantial increases in elasticity, and the Navy had a decrease in average elasticity. The average elasticity for DOD total increased from .133 to .268.
4. The decrease in college enrollments for 1973 appears to have helped all the Services except the Navy.

5. As expected, the elasticities for non-high school graduates were not significant. In most cases, the non-high school graduate variable did not enter the regression and in one case (1973 Marine Corps), the variable was significant at the 68 percent level.

Military Population Density:

1. The average elasticities for the Army and the Marine Corps were significant and positive for 1972 (.114 and .072).

2. The average elasticity for the Air Force for 1972 was significant and negative (-.094).

3. The average elasticity for the Navy for 1972 was not significant and negative (-.031).

4. The average elasticity for DOD total for 1972 was .059.

5. The average elasticities for all Services were positive for 1973. Upward shifts occurred in all cases.

6. The impact of high concentrations of military population is greatest for the Army and Marine Corps. The average elasticity was least significant for the Air Force for 1972, but this position was taken by the Navy in 1973.

Summary of Elasticity Comparisons

The average elasticities for each of the Services and DOD total for the five variables included in the regression models for 1972 and 1973 are consolidated in Table 39. Table 40 summarizes the shifts in the average elasticities from 1972 to 1973. For 1972, all five variables were positively related to Army volunteers; unemployment, pay and military population were negatively related to Air Force volunteers; pay was negatively related to Marine Corps volunteers; and pay and military population were negatively related to Navy volunteers. For DOD total, all five variables were positively related to volunteers.

For 1973, all five variables were positively related to Army and Air Force volunteers; unemployment and pay were negatively related to Marine Corps volunteers; and pay was negatively related to Navy volunteers. For DOD total, all five variables were positively related to volunteers.

In both years, the recruiter variable had the highest elasticity and was significant for the greatest number of cases. Unemployment was the second highest in 1972 but dropped to the least important in 1973. The

Table 39
AVERAGE ELASTICITIES

Variable	Army	Air Force	Marine Corps	Navy	DOD
<u>1972</u>					
Unemployment	.226	-.069	.036	.083	.170
Relative pay	.314	-.082	-.326	-.626	.007
High school/college	.209	.204	.093	.224	.133
Military population	.114	-.094	.072	-.031	.059
Recruiter	N	.828	.299	.549	N
<u>1973</u>					
Unemployment	.030	.121	-.082	.005	.028

Military population	.173	.019	.085	.004	.079
Recruiter	.007	.757	.232	.418	.285

Table 40
SHIFT IN ELASTICITIES FROM 1972 TO 1973

Variable	Army	Air Force	Marine Corps	Navy	DOD
Unemployment	-.196	+.190	-.118	-.078	-.142
Relative pay	+.430	+.165	-.149	+.530	+.246
High school/college	+.148	+.107	+.129	-.026	+.135
Military population	+.059	+.113	+.013	+.035	+.020
Recruiter	N	-.071	-.067	-.131	N

average change in unemployment elasticity was $-.142$ for DOD total. Relative pay was the least important variable for 1972 but it was the third most important variable in 1973. The average change in the pay elasticity was $+.246$ for DOD total. The high school graduate to college enrollment variable was the third most important in 1972 but increased to second in 1973. The average elasticity for this variable increased by $.135$ for DOD total. The military population density variable was the least important in 1972 but was second to last for 1973. The average elasticity for this variable increased by $.020$ for DOD total. While it was not possible to obtain a reliable estimate for the change in average recruiter elasticity between the two years, the estimates for the Air Force, Marine Corps, and Navy indicate that overall there was a slight decline in the average recruiter elasticity from 1972 to 1973.

ANALYSIS OF BLACK VOLUNTEERS

The state model with variables for unemployment, military pay, male high school graduates to male college enrollments, military population density and recruiter strength was used to analyze black volunteer enlistments for 1973. Adequate unemployment data for 1972 were not available and, therefore, the analysis covered only 1973. Volunteer data for all four Services and DOD total were obtained from the GRC data base. Unemployment data for blacks were obtained from the Bureau of Labor Statistics for 13 states for 1973. The BLS cautioned that the sample sizes used to calculate black unemployment rates were small and that large sample variances existed, thereby producing a low reliability factor. The BLS consented to allow GRC to use the black unemployment data for regression analysis, but since the data have not been officially published and also due to the low reliability it was requested that the actual figures not be revealed. The data used for relative pay, male high school graduates to male college enrollments, military population density and recruiter strength are the same used for analysis of total volunteers.

Since the data were limited, it was felt that it would not be cost effective to make regressions for all volunteer categories for each Service. Instead, regressions were made for two volunteer categories, high school graduates and non-high school graduates.

Table 12 summarizes the results of the regression runs for black volunteers, and Table 41 consolidates the elasticities for each Service and DOD total by variable type. In the ensuing subsections the elasticity of each variable with respect to each Service and DOD total is discussed, and finally a comparison of the elasticities for black volunteers is made with those for total volunteers.

Unemployment Elasticities

The unemployment variable did not enter the regressions for either high school graduates or non-high school graduates for any of the Services or DOD total. While the implication of the observed results is that unemployment rates do not have an effect on black volunteers for any of the Services, it appears logical to conclude that the unreliability of the black unemployment data was a major factor in producing a non-significant result. Consequently, it is not possible to make direct assertions regarding the impact of unemployment rates on black volunteers for any of the Services.

Recruiter Elasticities

The recruiter elasticity was positive for high school graduates in all cases except the Navy where the variable did not enter the regression. The recruiter elasticity for high school graduates was high for the Army (1.676), Marine Corps (.682) and DOD total (1.053), but due to large sampling variances none of these elasticities were significant at the 68 percent confidence level. The elasticity for the Air Force (.729) was significant at the 68 percent confidence level.

For non-high school graduates, the variable did not enter the regression for the Army, Air Force, Navy and DOD total. The recruiter elasticity for the Marine Corps (1.555) was positive and significant at the 95 percent confidence level.

In comparing the recruiter elasticities of high school graduates with non-high school graduates, the elasticity was higher for high school graduates than non-high school graduates for the Army, Air Force and DOD total. The elasticity was higher for non-high school graduates for the Marine Corps, and there was no observed difference for the Navy. Overall, black volunteers were most responsive to the recruiting efforts of the Marine Corps, and the recruiting efforts of the Navy had no impact on black volunteers.

Table 41
ELASTICITIES FOR BLACK VOLUNTEERS

* Significant at the 68 percent confidence level.

** Significant at the 90 percent confidence level.

*** Significant at the 95 percent confidence level.

Pay Elasticities

The pay elasticities for high school graduates were positive and significant for the Army (3.434), Air Force (1.524), Marine Corps (1.672) and DOD total (2.032). The pay variable did not enter the regression for the Navy. The elasticity was significant at the 90 percent confidence level for the Army and significant at the 68 percent confidence level for the Air Force, Marine Corps and DOD total.

The pay elasticities for non-high school graduates were positive but not significant for the Army, Marine Corps, and DOD total. The pay variable did not enter the regression for the Air Force and Navy. A comparison of the elasticities reveals that the elasticities for high school graduates were consistently higher than non-high school graduates except for the Navy where neither variable entered the regression. Overall, black volunteers were most responsive to the pay variable for the Army, and least responsive to this variable for the Navy.

High School to College Ratio

The elasticities for male high school graduates to male college enrollments were positive for high school graduates for all Services and DOD total. However, this variable was significant in only two cases, the Army (68 percent level) and DOD total (68 percent level).

The elasticities for non-high school graduates were positive and significant (68 percent level) for all cases except the Air Force where the variable did not enter the regression. A comparison reveals that the elasticity was higher for high school graduates for the Army and Air Force, and higher for non-high school graduates for the Marine Corps and Navy. The elasticity is only slightly higher for high school graduates for DOD total. Overall, black volunteers were most responsive to the high school to college ratio for the Army, and least responsive to this variable for the Air Force.

Military Population Density

The elasticities for military population density for high school graduates were positive for all Services and DOD total. The elasticity was significant at the 95 percent confidence level for the Navy, and significant at the 68 percent confidence level for the Air Force and DOD total.

The elasticities for non-high school graduates were positive in all cases except for the Marine Corps where the variable did not enter the regression. The elasticities were significant at the 68 percent confidence level for the Army and Air Force. A comparison reveals that the elasticities are higher for non-high school graduates than high school graduates for the Army and Air Force, and higher for high school graduates for the Marine Corps, Navy, and DOD total. Overall, there was little difference among Services in responsiveness to this variable except for the Marine Corps which had the lowest elasticities.

Comparison of Black Volunteers with Total Volunteers

A comparison of the elasticities for black volunteers was made with respect to the counterpart elasticities obtained for total volunteers. Table 42 summarizes the differences between the two groups. Each difference is defined as the black elasticity minus the elasticity for total volunteers. Dashes in the table indicate that the variable did not enter the regression in either case.

There are 50 entries in Table 42, and of these, five are dashes, seven are minuses, and 38 are pluses. The following conclusions may be made on the basis of the results in the table.

1. Overall, black volunteers were more responsive to changes in the five variables than were non-black volunteers.
2. The data are not adequate to make comparisons regarding unemployment rates.
3. Black volunteers are more responsive than are non-black volunteers to changes in relative pay.
4. Black volunteers are more responsive than are non-black volunteers to changes in the ratio of male high school graduates to male college enrollments.
5. Black volunteers are slightly more responsive than non-black volunteers to changes in the military population density.
6. Black volunteers are more responsive than non-black volunteers to changes in the level of recruiters.
7. If the total of differences (bottom row of Table 42) is used to measure the relative response between black volunteers and non-black volunteers, the Marine Corps and the Army have about twice the differential in elasticity as the Air Force and Navy.

Table 42
DIFFERENCES IN ELASTICITIES BETWEEN BLACK
VOLUNTEERS AND TOTAL VOLUNTEERS^a

Variable and volunteer category	Army	Air Force	Marine Corps	Navy	DOD
Unemployment					
High school graduates	-	-.171	+0.075	-.230	-.111

Total differences	6.003	3.166	6.681	3.418	4.181

^aThe differences are given as black elasticities minus total elasticities.

INTERPRETATION OF RESULTS - PROBLEMS AND PITFALLS

The elasticities obtained in this analysis must be interpreted with caution because of the inherent uncertainties and inadequacies associated with using the general linear regression model. In the first instance the values obtained for the coefficients of multiple correlation (R^2) are not very large, and in the second instance the sampling variances for the regression coefficients are relatively large. While the values obtained in this study compare favorably with those found in previous studies, the implication is that there is a substantial amount of variation in the dependent variable (the rate of first-term volunteer enlistments) which is not explained by the model.

There are a number of factors which may explain the incidence of a low value for the coefficient of multiple correlation. Among the more important are:

1. Significant variables have been omitted from the model.
2. Measurement errors in the data.
3. The linear models are not representative of the true relationships.

It is not possible to specify on an a priori basis all the relevant variables that affect the psychic decision making process which determines individual preferences for enlisting in the Armed Services. However, it is reasonable to conclude from the analyses that the five variables included in the model are important in explaining first-term volunteer enlistments, and while it is true that the addition of other variables would increase the value of R^2 , the crucial question is whether the regression coefficients in the current model are affected as a result of omitting other variables.

Frequently, the omission of significant variables from the model will produce a serial correlation in the regression residuals. The regression estimates will be unbiased, but they will be subject to large sampling variances and the level of confidence will be reduced for a given range of predictions.

The residuals in the regression models were tested for the presence of serial correlation by calculating a Durbin-Watson d Statistic. The results substantiate the hypothesis that there is no serial correlation

present, and it is concluded that the omission of other variables does not significantly alter the conclusions.

Measurement errors may be another cause of small values for the coefficient of multiple correlation. That is, the observed values are not representative of the true values. An examination of the data and the sources of the data would suggest that all the data are reliable except the data for the relative wage, Army recruiting data by state, and black unemployment data. While the data used for military pay should be representative, it is doubtful that the data used for the civilian wage is representative of the real wage. This applies not only to this study but to the previous studies as well.

The use of the average incomes for manufacturing payrolls or average incomes for males between the ages of 17-21 for all occupations fails to measure real income because many of these individuals have the option of living at home with their parents. Clearly, if room and board are supplied by a young male's family, his real income is higher than if he had to pay for it.

Presumably, average incomes for manufacturing payrolls or average incomes for males between the ages of 17-21 are correlated closely with real income and are an acceptable measure to use in the ratio of military income to civilian income. While the tests for serial correlation in this study seem to indicate that the use of average incomes for males between the ages of 17 and 21 is not a significant source of error, it should be recognized that it may be a possible source of error in both the pay and the unemployment elasticities.

The Army collects recruiting data on the basis of RMS and since RMS boundaries and state boundaries overlap in almost every instance it is difficult if not impossible to obtain an accurate estimate of the numbers of recruiters by state. An algorithm was developed for allocating recruiters to states on the basis of ZIP codes and as long as the number of recruiters was distributed approximately proportional to the ZIP code areas, this algorithm should provide good results.

As mentioned earlier, data for black unemployment rates are based on small samples and the sampling variances associated with the data are so large as to make the observed values highly questionable.

Finally, a small value for the coefficient of multiple correlation may be due to the fact that the linear models are not representative of the true relationships. The importance of this implication is that the elasticity estimates may be very good for marginal changes around the present values, but any long-term projections beyond the range of the sample data are subject to a high level of uncertainty.

When interpreting the elasticity estimates, it is essential that the confidence intervals of the elasticities are given due consideration. The elasticity estimate is the average elasticity measured at the mean values of the data series, and the confidence interval is a measure of how good the average elasticity will be for predicting future responses. For example, if the average elasticity is .328 with a standard error of .262, then a prediction can be made with 68 percent confidence that the true elasticity is between .066 and .59. Clearly, if the confidence interval were smaller the precision in the prediction could be increased for a given confidence level. For example, if the standard error in the elasticity was .1, then it could be said with 68 percent confidence that the true elasticity is between .228 and .428.

To summarize the purpose of this subsection, it can be said that the conclusions of the analyses must be tempered by an awareness of the limitations and uncertainties associated with the analytical and statistical techniques used.

CONCLUSIONS

The conclusions of the analyses may be summarized concisely as follows:

Unemployment Elasticities

1. Unemployment elasticities are variable depending upon whether unemployment rates are high or low. A significant downward shift in the unemployment elasticities occurred from 1972 to 1973.
2. Unemployment elasticities are significant for DOD total volunteers when overall unemployment rates are greater than 5 percent.
3. Unemployment elasticities are not significant for DOD total volunteers when labor markets are tight, i.e., when the overall unemployment rate is 5 percent or less.

4. The average of the unemployment elasticities for the two years was highest for the Army $[(.226 + .030)/2 = .128]$.

5. Unemployment elasticities are not significant for the Marine Corps and Navy.

6. Unemployment elasticities were not significant for the Air Force for 1972 but were significant for 1973. This may be an indication that the Air Force was demand limited in 1972 and supply limited in 1973. If this is true, then the 1973 average elasticity of .121 is the best estimate of unemployment elasticity for the Air Force.

7. Unemployment elasticities are greater for Category I-II than for Category I-III.

8. Unemployment elasticities are higher for 17-18 year olds than 19-21 year olds for the Army, but for the other Services there is no difference.

Recruiter Elasticities

1. Recruiter elasticities are the highest and most consistent of the five variables used in the model.

2. Due to data inadequacies, the results for the state models for the Army and DOD total are inconclusive. However, results from the RMS model indicate an average elasticity of .976 for the Army.

3. Based on the state models, the recruiter elasticities are greatest for the Air Force, with an average elasticity of .792 for the two years.

4. The Marine Corps has the lowest recruiter elasticities. The average for the two years was .266.

5. The average recruiter elasticity for the Navy was .483.

6. There was a slight downward shift in the recruiter elasticities from 1972 to 1973.

7. Recruiter elasticities are higher for 17-18 year olds than 19-21 year olds.

8. Recruiter elasticities are higher for Category I-II than Category I-III for the Army and Navy.

9. Recruiter elasticities are higher for Category I-III than Category I-II for the Air Force and Marine Corps.

10. Recruiter elasticities are higher for high school graduates than non-high school graduates for the Army, Marine Corps, and Navy. They are lower for the Air Force.

Pay Elasticities

1. The cross-sectional pay elasticity may be more a measure of regional or state differentials than differences in real income.

2. The average pay elasticity for the Army was .529.

3. The pay elasticities for the Air Force are not significant.

4. The average pay elasticity for DOD total was .130.

5. The average pay elasticity for the Marine Corps was -.400.

6. The average pay elasticity for the Navy was -.361.

7. There was an upward shift in the pay elasticities from 1972 to 1973.

8. The pay elasticities are higher for 19-21 year olds than 17-18 year olds.

9. The pay elasticities are higher for Category I-III than Category I-II.

10. The pay elasticities are higher for non-high school graduates than high school graduates.

High School/College Elasticities

1. The high school to college elasticities are positive and significant.

2. The average elasticity for DOD total was .200.

3. The average elasticity for the Army was .283.

4. The average elasticity for the Air Force was .257.

5. The average elasticity for the Marine Corps was .158.

6. The average elasticity for the Navy was .211.

7. There was an upward shift in average elasticities from 1972 to 1973.

8. The average elasticities are not significantly different by age.

9. The average elasticities are higher for Category I-II than Category I-III.

10. The average elasticities are higher for high school graduates than non-high school graduates.

Military Population Density Elasticities

1. The military population density elasticities are positive and significant for the Army and Marine Corps.
2. The elasticities are negative and significant for the Air Force for 1972, and not significant for 1973.
3. The elasticities are not significant for the Navy.
4. The average elasticity for DOD total was .069.
5. The average elasticity for the Army was .144.
6. The average elasticity for the Air Force was -.038.
7. The average elasticity for the Marine Corps was .078.
8. The average elasticity for the Navy was -.014.
9. The average elasticities are higher for 19-21 year olds than 17-18 year olds.
10. The average elasticities are slightly higher for Category I-III than Category I-II.
11. The average elasticities are higher for non-high school graduates than high school graduates.
12. There was an upward shift in the elasticities from 1972 to 1973.

Policy Implications

A number of policy implications may be drawn from the above conclusions. First, the unemployment elasticities indicate that it is more difficult to recruit volunteers during upswings in the economy when unemployment rates are declining than during downswings when unemployment rates are rising. Since the recruiter elasticities are significant for all Services, they can counteract adverse changes in volunteer rates caused by unemployment changes by changing the number of recruiters in the field. The empirical evidence indicates that the Army and Air Force are more susceptible to changes in unemployment rates and, therefore, their recruiting programs should pay careful attention to economic trends in the civilian economy so that adverse moves in unemployment rates may be anticipated.

A major objective of the Armed Services is to increase the quality of the enlisted force. One of the primary methods of accomplishing this objective is to increase the number of volunteers who are high school

graduates and Category I-II. These volunteer categories have relatively high elasticities for the high school/college variable and the military population density variable, and if recruiting efforts are concentrated in areas where these ratios are highest an increase in recruiter productivity may be realized.

Chapter 3
AIR FORCE TIME SERIES REGRESSION ANALYSIS

During the CY71 to CY73 time period, the Air Force has reached its quota each month with a very high percentage of high school graduate enlistments. Examination of the data for different educational and mental category groups shows that all non-high school graduate groups and Category IV high school graduate groups are clearly demand limited. Our analysis, thus, is concerned mainly with measuring the effects of policies and programs on the Category I-III high school graduate groups.

Regression runs were made using CY71 through CY73 time series of the following groups as dependent variables.

- o High school graduate volunteers of Mental Categories I, II, III, and IV.

- o High school graduate volunteers of Mental Category I-III and I-IV groups.

The time series model is described in App C. The variables used in this analysis are listed in Table 43 with their mean values, standard deviations and program names. The description and actual values of the variables are given in App D. The regression results for the groups listed above are given in Tables 44-49. These tables give the coefficients, standard errors, F values and elasticities for each independent variable that enters a particular regression. A more detailed interpretation of the output tables of the regressions is given in App E. Tables 44-47 give results for Category I-III and Category I-IV high school groups. Tables 48 and 49 give the regression results for Category I, II, III and IV high school graduate groups individually.

STRATEGY OF REGRESSION RUNS

As a result of several regressions on different population groups using only the major incentive programs, it was found that the fit to the data was poor ($R^2 \sim .4$). The inclusion of a variable which measured the demand for volunteers improved the fit considerably ($R^2 \sim .85$). This variable was calculated by subtracting the monthly number of draft-motivated enlistments entering the Air Force from the Air Force quota. This variable thus tracks the Air Force demand for volunteer enlistments. During periods of large draft calls, the variable is small, reflecting the large supply of draft-motivated personnel available to the Air Force. This variable is found to be highly correlated with Air Force volunteer enlistment data indicating that demand rather than supply is the major influence on Air Force volunteer enlistments. The quota variable appears in all regression equations that it is allowed to enter and occurs as the variable with greatest significance. When the quota variable is brought into the regression equation alone, residuals are small and R^2 is at least .60.

Table 50 gives the correlation matrix for the independent variables. Military pay and recruiting are highly correlated variables and were entered into separate sets of regression equations in order to measure their effectiveness. Thus, for each dependent variable, two sets of regressions were run, one including military pay and one including recruiting.

AIR FORCE PROGRAM EFFECTS

Programs and policies measured in this analysis are described below.

Demand Variable (AFQOT-DM)

The regressions show that changes in high school graduate volunteer groups are very highly dependent on changes in demand for volunteers as measured by the variable calculated by subtracting monthly draft-motivated enlistments from the monthly quota. In Tables 48 and 49, the F values for this variable (with the exception of the Category IV high school graduate group) ranges from 54 to 134, indicating strong significance. The strong significance of this variable probably indicates that the Air Force is demand limited even for Category I-III high school graduate volunteer groups.

Military Pay

Among the Air Force volunteers, the increase in military pay relative to civilian wages caused an increase in Mental Category I-III high school graduate accessions and had no significant effect on non-high school or Category IV high school graduates. Table 51 summarizes the elasticities for the various groups.

Table 51
MILITARY PAY ELASTICITIES FOR DIFFERENT
AIR FORCE MENTAL CATEGORY GROUPS

	Category I HS	Category II HS	Category III HS	Category IV HS	Category I-III HS	Category I-III NHS
Lower estimate	.83±.12	.63±.09	.12±.20	0	.63±.10	0
Upper estimate	1.0±.13	.76±.13	.59±.13	0	.42±.16	0
Best estimate	.91±.13	.69±.11	.35±.25	0	.53±.13	0

Pay elasticities for Category I high school graduates are significantly higher than the elasticities for Category II and III high school graduates. The lower elasticities and significance for the Category III groups reflect that this group was probably demand limited during this time period.

In making a best estimate of pay elasticities, the main factor to be kept in mind is that a pay elasticity is specific to a given model and can only be used in the context of that model. Also, any given model contains assumptions which are part of the pay elasticity measurements. Measurements given in Tables 44-49 give several different pay elasticity measurements using different variable combinations. For instance, from Table 44 the first column gives a pay elasticity of .623. This linear model assumes that pay was the only significant incentive variable. Columns 2 and 3 attribute separate independent linear effects to other variables such as unemployment, options and print media. Each of these models also assumes no independent effect due to additional recruiting since that variable cannot be entered due to its high correlation with pay.

The best estimates given in Table 51 are simply derived from averaging the high and low estimates from the regressions. The errors are taken either from an average of the standard error of the measurements or are enlarged to include the range between the higher and lower estimates. The error, thus, cannot be interpreted in a statistical sense, but actually convey more information than an ordinary statistical error. The errors cover not only the statistical uncertainty from a single model but the range of sensitivity of the elasticity to different models. This source of uncertainty is often the dominant one and often is not included in policy decisions.

Air Force Recruiting

The response to recruiting by Mental Category I, II and III high school graduates is quite large, with elasticities ranging from .87 to 1.29. Recruiting has had no significant effect on Category IV high school graduates or Category I-III non-high school graduates. Table 52 summarizes the range of recruiting elasticities and standard errors measured for the different Air Force groups from Tables 44-49.

Table 52
RECRUITING ELASTICITIES FOR DIFFERENT
AIR FORCE MENTAL CATEGORY GROUPS

	Category I HS	Category II HS	Category III HS	Category IV HS	Category I-III HS	Category I-III NHS
Lower estimate ^a	1.17±.18	.91±.13	.87±.17	0	.89±.13	0
Upper estimate ^a	1.30±.30	1.06±.20	.83±.25	0	1.13±.16	0
Best estimate ^b	.93± .30	.74±.25	.64±.21	0	.76± .25	0

^aNo independent pay effect assumed.

^bSee text for explanation.

The results show generally larger elasticities for the higher mental groups indicating that the percentage increase was greater among the larger mental groups for the Air Force. Again, the lower elasticity for Category III high school graduates probably indicates that this group was demand limited during part of the 3-year time period.

The elasticities in Table 52 are derived from a model which attributes no independent effects to the pay raise. For this reason the elasticities represent upper limits to recruiting elasticities. In other words, the model attributes all increases generally to recruiting, i.e., the same increases would have taken place if recruiters were increased but no pay increase was given. This is an unlikely assumption. On the other hand, it is also unlikely that the pay raise alone without additional recruiters would have increased the group to the same degree. The effect of recruiters is indicated strongly by the fact that the significance as measured by the F value is generally greater for the recruiters than for military pay variables.

To arrive at a best estimate, the average of the two estimates given in Table 52 is used as an upper limit since no military pay is included. A lower limit of zero does not seem feasible due to the large significance of the recruiter variable. A lower limit of one-half the upper limit is assumed here. For instance, for the Category I high school graduate group, the upper limit is $(1.17 + 1.30)/2 = 1.23$, while the lower limit is $1.24/2 = .62$, and the best estimate is $(1.23 + .64)/2 = .94 \pm .30$.

Print Media Advertisements

Table 53 summarizes the elasticities measured for the print media advertisements variable from Tables 44-49.

Table 53
ELASTICITIES FOR PRINT MEDIA ADVERTISEMENTS FOR
DIFFERENT AIR FORCE MENTAL CATEGORY GROUPS

	Category I HS	Category II HS	Category III HS	Category IV HS	Category I-III HS
Lower estimate	0	.025 \pm .025	.065 \pm .03	0	.03 \pm .02
Upper estimate	0	.04 \pm .02	.08 \pm .03	0	.06 \pm .02
Best estimate	0	.033 \pm .02	.073 \pm .03	0	.045 \pm .02

The print media variable generally enters with a 3-month delay. The best estimates and errors in this case are derived from simple averages of the upper and lower estimates and errors.

Unemployment Variable

Table 54 summarizes the elasticities for different groups for the youth unemployment variable.

Table 54
UNEMPLOYMENT ELASTICITIES FOR DIFFERENT
AIR FORCE MENTAL CATEGORY GROUPS

	Category I HS	Category II HS	Category III HS	Category IV HS	Category I-III HS
Lower estimate	0	.38 \pm .15	.25 \pm .24	0	.20 \pm .18
Upper estimate	.2 \pm .2	.42 \pm .16	.32 \pm .21	0	.40 \pm .15
Best estimate	.1 \pm .2	.40 \pm .16	.28 \pm .23	0	.30 \pm .17

The variable generally entered with a 1-month delay in the regression. The best estimates in Table 54 are arrived at by simply averaging the upper and lower bounds and errors.

Air Force Options

The Air Force options available to non-prior service accessions increased from only two in FY71 to six in December 1973. These options included such changes as guaranteed service school choices and new 6-year commitments in exchange for E-2 entrance grades. Table 55 summarizes the elasticities measured for the average option change during this period.

Table 55
OPTION ELASTICITIES FOR DIFFERENT AIR FORCE
MENTAL CATEGORY GROUPS

Lower estimate	0	0	.09 \pm .11	0	.10 \pm .08
Upper estimate	.07 \pm .13	.04 \pm .08	.24 \pm .14	0	.12 \pm .11
Best estimate	.03 \pm .13	.02 \pm .08	.16 \pm .13	0	.11 \pm .10

The variable enters only weakly in the regressions with F levels generally below 1. The best estimate values are again obtained by averaging the upper and lower bounds and errors.

Other Service Program Effects

Two variables were entered into the regression to determine the influence of other Service programs on Air Force enlistments. The Army and Marine Corps bonus programs were depicted by two bonus variables which mark the start of the \$1500 and \$2500 bonus. Of all programs implemented by the Marine Corps and Army, the bonus was thought to be the one which might influence Air Force enlistments the most. For the Navy, a variable was included which marked a huge increase in Navy demand for volunteers during the period June-August 1972. During this period, Navy quotas rose substantially. This period allows a measurement of the effect on other Service accessions of large increases in Navy requirements.

The bonus variables show no effect on Air Force enlistments. They do not enter the regressions at any stage. Generally, no significant drop in Air Force volunteer enlistments for any group can be attributed to the Army and Marine Corps bonus programs.

The Navy quota variable, on the other hand, does enter negatively and is generally significant. Table 56 summarizes the effects of the Navy quota variable.

Table 56
MONTHLY LOSS IN AIR FORCE VOLUNTEER ENLISTMENTS DUE TO
INCREASE IN NAVY QUOTA IN JUNE-SEPTEMBER 1972

	Category I HS	Category II HS	Category III HS	Category IV HS	Category I-III HS
Lower estimate	-35±17	-108±93	0	-120±71	-278±256
Upper estimate	-36±20	-222±92	-387±164	-123±69	-841±216
Best estimate	-35±19	-165±92	-194±164	-121±70	-656±236

The data would indicate that there is a cross elasticity between Navy requirements and Air Force enlistments. During June-September 1972, the monthly quota for males in the Navy almost doubled over previous months, from around 7500 to 14,000. This doubling of the quota only caused a loss of Air Force Category I-III high school graduate enlistments of 650 per month. Roughly, for each change of 1000 in the monthly Navy quota, Air Force Category I-III high school graduate enlistments changed by 100.

CONCLUSIONS

A basic concept in understanding the monthly variation in Air Force volunteer data over the last 3 years is whether volunteers are supply limited or demand limited. For the Air Force, all non-high school graduate groups and Category IV high school graduate groups are currently demand limited, i.e., the Air Force could increase enlistments in these groups with simple policy changes. There is also evidence that the Category III high school graduate group is currently demand limited. Analysis of Category I, II, III high school graduates indicates that variations in volunteer enlistments in these groups are primarily attributable to three variables: Air Force quota for volunteers, military to civilian pay ratio, and number of recruiters. Of much lesser importance in explaining variations are Navy quota changes, new options, unemployment and print media advertisements. Clean separation of the effects of military pay and recruiting is complicated by their multicollinearity, but the time series analysis can provide an upper limit to the effects of pay and recruiting. Table 57 gives the average F values and elasticities of the variables in the regressions for Category I-III high school graduates. The F values provide a relative indication of the importance of variables in explaining variations in volunteer enlistments.

The elasticities can provide estimates of how percentage changes in each of the variables will affect percentage changes in Category I-III high school volunteer enlistments. The elasticity is the percentage change in Category I-III high school volunteer enlistments for each 1 percent change in the independent variable. For instance, if the recruiting force were increased by 1 percent over the average of 1800 (Table 43) or 1.8 recruiters, the percentage increase in Category I-III high school graduate enlistments would be .76 percent or $(.76)(4340) = 33$ enlistees.

Table 57
 SUMMARY STATISTICS FOR AIR FORCE CATEGORY I-III
 HIGH SCHOOL GRADUATE DATA

Variable	F values	Estimated elasticities
Volunteer quota	140	$.81 \pm .07$
Recruiting	39	$.76 \pm .25$
Military pay	20	$.53 \pm .13$
Navy quota dummy	10	-100 ^a
Unemployment	4	$.30 \pm .17$
Print media advertisements	3	$.05 \pm .02$
Options	1	$.11 \pm .10$

\$2500 bonus	0	0

^aMonthly change in Air Force Category I-III high school graduate enlistments for each 1000 change in Navy quota.

Chapter 4
NAVY TIME SERIES REGRESSION ANALYSIS

Time series regression analysis was performed on the following groups of Navy volunteers.

- o Category I, II, III and IV high school graduate volunteers.
- o Category I-III high school graduate volunteers.
- o Category I-IV high school graduate volunteers.
- o Category I-III non-high school graduate volunteers.

Monthly data from January 1971 to December 1973 were used in the analysis. The means and standard deviations of variables used in the analysis are given in Table 58. The time series data for the variables are described in App D. The correlation coefficients among the variables are given in Table 59.

REGRESSION STRATEGY

The Navy time series analysis was complicated by several factors as listed below:

- o The multicollinearity among key program variables was higher than for other Services.
- o The Navy changed its method of computation of AFQT scores during this period.
- o The Category IV high school graduate group fluctuated widely with no explicit policy.
- o No data on Navy print media advertisements were available.

The high degree of multicollinearity among variables for the Navy makes separation of the effects of different programs difficult. For instance, Table 59 shows that the military pay variable has three variables (recruiters, options, and bonus increment) which have correlation

coefficients above .68. The recruiting variable has four other variables with correlation coefficients above .76. Estimates of recruiting and pay elasticities are given under the assumption that they are independent of each other. Estimates of the effect of bonus on the Navy are given here, but are clouded by multicollinearity problems. Estimates of unemployment and options are not given since these effects are small and cannot be measured in association with other variables due to multicollinearity.

During this period, the Navy also changed its method of determining AFQT scores in January 1973. The data for individual mental category groups would indicate a difference in classification schemes for mental category groups occurred at the time of the changeover. For instance, seasonally adjusted data for Mental Category I data show a clear drop at January 1973 when the AFQT scoring method changed. Other groups show changes also in January 1973, particularly for the first two months of the new system. This change in AFQT classification methods introduces additional problems when trying to analyze individual mental category groups.

The data would also indicate that the Navy during this time period has been supply limited during portions of this period and demand limited during other parts of the period. Navy quotas increased dramatically for a four-month period in 1972, and during this period Category I-III high school graduates were clearly supply limited. At other periods, the Category I-III high school volunteer groups were probably demand limited. Category IV high school graduate enlistments are a good means of monitoring the transition from supply to demand limited since they appear to be used only when the pool of Category I-III high school graduates is exhausted. This situation makes the Navy data harder to interpret than the Air Force data which are nearly always demand limited during the entire period.

In order to obtain estimates of the recruiting and pay elasticities and the effect of the bonus, recruiting and pay variables were run separately because of their multicollinearity. In addition, separate runs were made using the volunteer quota variable since the Navy was probably

demand limited for volunteers during part of this period. Results presented include those for Category I-III and I-IV high school graduates and Category I-III non-high school graduates. The individual mental category runs are not presented mainly because of difficulty of interpretation due to the change in AFQT scoring methods. The results are given in Tables 60-67.

Volunteer Quota Variable

The volunteer quota variable enters the Category I-III high school graduate regressions (tables 60 and 61) at a significant level, which is markedly lower than for the Air Force regression runs. This would indicate that Category I-III high school graduate volunteers for the Navy depend much less on quota considerations than Air Force volunteers in the same categories. This fact would also seem to suggest that the number of high school graduates taken in for at least some periods did depend on quota for the Navy, whereas for the Air Force, the dependence on quota was for the entire time period considered in the analysis. The quota variable, however, enters at a much higher significance level for Category I-IV high school graduate regressions (Tables 62-65) than Category I-III high school graduate regressions. This indicates that Category IV high school graduate volunteers were used to fill quotas when Category I-III high school graduate volunteers were supply limited. The highest R^2 in all Navy regressions occurs for the Category I-IV high school graduate group. With the two variables of volunteer quota and either pay or recruiting, R^2 values of .86 are obtained. Comparison of regression runs with and without the quota variables shows that the quota variable increases the R^2 significantly in each case.

Military/Civilian Pay Ratio Variable

Table 68 summarizes the pay elasticities from the regression runs in Tables 60-67. The lower level estimates are derived from regression runs with the volunteer quota variable, while the upper estimates are derived from regression runs without the volunteer quota variable. The best estimate in each case is derived from an average of the estimates. In the case of the Category I-IV high school group, the error is expanded to include the upper and lower estimate. The higher estimate of elasticities in the Category I-IV group is derived from a regression with

negative bonus effects. Generally, the rest of the estimates are derived from regression runs where the bonus or unemployment variables did not enter or were not allowed to enter due to the high degree of multicollinearity. If it is assumed that the bonus and unemployment did have effects, the pay elasticities would be larger for the Navy groups.

Table 68
MILITARY CIVILIAN PAY RATIO ELASTICITIES FOR
DIFFERENT NAVY MENTAL CATEGORY GROUPS

	Category I-III HS	Category I-IV HS	Category I-III NHS
Lower estimate	.35 ± .11	.12 ± .08	.97 ± .28
Upper estimate	.52 ± .15	.70 ± .17	.97 ± .29
Best estimate	.44 ± .13	.41 ± .29	.97 ± .29

Recruiter Variable

Table 69 summarizes the elasticities for the different groups for the recruiter variable. The lower estimates are derived from regressions with the volunteer quota variable, while the upper estimates come from regressions without the quota variable. The best estimates are calculated from the means of the upper and lower estimates. The elasticity estimates measured here exclude the effects of bonus, unemployment or options due to their collinearity with the recruiting variable. Generally, assuming an effect due to unemployment or bonus would drive the recruiting elasticities higher.

Table 69
RECRUITING ELASTICITIES FOR DIFFERENT
NAVY MENTAL CATEGORY GROUPS

	Category I-III HS	Category I-IV HS	Category I-III NHS
Lower estimate	.32 ± .08	.11 ± .06	1.03 ± .20
Upper estimate	.34 ± .11	.70 ± .37	1.19 ± .24
Best estimate	.33 ± .10	.40 ± .30	1.11 ± .22

Other Variables

The remaining variables of bonus high school (\$1500), bonus increment (\$2500), options, and unemployment are obscured by collinearity problems. The effect of all these variables is generally smaller than pay and recruiting, and since each one is highly correlated with either pay or recruiting, accurate measurement is difficult.

The bonus increment variable is not as highly correlated with pay and recruiting as the \$1500 bonus variable. The regression runs for Category I-III high school groups show that this variable is not significant when allowed to enter with pay or recruiting. The \$1500 bonus variable also does not enter the regression with these variables. This evidence would suggest that the Navy has not lost Category I-III high school graduates due to the bonus programs of the other Services. The bonus variables also do not enter the Category I-IV regressions when the volunteer quota variable is used, although a negative effect for the bonus does appear without the quota variable. A rough conclusion from these data is that the Navy high school group has not been significantly affected by the bonus.

CONCLUSION

Table 70 summarizes the significance of the variables for the Category I-IV and Category I-III high school groups. The volunteer quota variable is the most significant in both groups although with a much lower F value for the Category I-III group. This probably indicates that the Category I-III group is supply limited by the Navy, while the Category I-IV group is demand limited. The military pay variable and recruiting variable are roughly of equal statistical significance in explaining variation in Category I-III high school volunteers. No other variables appear significant for this group.

The R^2 values for the regression are significantly higher for the regression having the quota variable included indicating the dependence for at least part of the 1971-1973 period of high school graduate volunteer enlistments on quotas.

The \$1500 and \$2500 bonuses appear to have no significant effect on Category I-III high school graduate enlistments in the Navy.

Chapter 5
MARINE CORPS TIME SERIES REGRESSION ANALYSIS

The results of the regression analysis of Marine Corps volunteer enlistments are presented in this chapter. The volunteer groups studied are the following:

- o Mental Category I-III high school graduates
- o Mental Category I-IV high school graduates.
- o Mental Category I-III non-high school graduates.

The program variables used in this analysis are described in App D. Mean values and standard deviations for the variables are listed in Table 71. The correlation matrix of the independent variables is shown in Table 72. The Marine Corps had no paid media advertising during this period and changes in options were minimal. The only variables included on the analysis were pay, recruiting, bonus, unemployment and options. Because of the high degrees of correlation among the pay, recruiting, unemployment and options variables, separate runs were made for each of the variables. This was done to obtain upper and lower bounds on the variable effects.

REGRESSION RESULTS

The actual regressions are shown in Tables 73-78. Tables 73, 74, 75 and 76 contain the results for Marine Corps high school graduate groups, while Tables 76, 77 and 78 give results for Category I-III non-high school graduate groups.

Of the Services measured, the Marine Corps data have the largest unexplained variance. The results for the high school graduate group, in general, have extremely low R^2 values. The non-high school graduate groups, on the other hand, show reasonably high R^2 values. The effects of each of the variables is described below.

INDEPENDENT VARIABLE EFFECTS

The independent variable effects are summarized in Table 79 according to the variable elasticities. The measurements represent an average of the highest and lowest elasticity values for each variable taken over all regressions which could include the variable. The error is derived either from an average of the standard errors or is enlarged to include the span between the highest and lowest estimates.

Table 79
PROGRAM AND UNEMPLOYMENT ELASTICITIES FOR DIFFERENT
MARINE CORPS MENTAL CATEGORY GROUPS

	Category I-III HS	Category I-IV HS	Category I-III NHS
Military-civilian pay ratio	.15±.08	.20±.15	.76±.12
Recruiters	.08±.11	0	.98±.12
\$1500 bonus	0	0	0
\$2500 Bonus	0	0	0
Youth unemployment rate	.29±.12	.68±.14	0

Military Pay

Pay elasticities for high school graduates are extremely low -- between .1 and .2 generally, but pay elasticities for non-high school graduates are close to .76. Pay elasticities for high school graduate groups are small and much less significant than for other Services. The pay raise had very little effect on Marine Corps high school graduate volunteer enlistments. Table 73 shows the military pay variable, when entered alone, to have elasticity at around .1; however, Table 75 shows that with unemployment, the pay elasticity increase to .24, and the R^2 for the regression increases substantially. The results suggest three possible

explanations. First, the Marine Corps high school graduate enlistments could be sensitive to unemployment rates, and the effect of the pay raise in terms of increasing enlistments was cancelled partially by lower unemployment rates. Second, the effect is only a spurious correlation caused in part by the correlation (-.54) between the two variables. Third, the Marine Corps recruiters did not push high school graduate enlistments.

For non-high school graduates, the pay raise is significant and high. The response of the non-high school graduate to the pay raise is similar to other Services. This might suggest that the Marine Corps recruiters were oriented primarily to the non-high school graduate volunteer market.

Recruiters

Overall recruiting activity is not highly correlated with high school graduate accessions. The additional recruiters put out by the Marine Corps were able to enlist less than one additional high school graduate per year. In addition, recruiting variables occur in regressions with small elasticities and the recruiting variable must be forced into the regressions for Category I-III high school graduates when this group is regressed on recruiting alone.

Recruiting elasticities for non-high school graduates are large and significant -- $1.15 \pm .17$. The recruiters were able to significantly expand the non-high school market, but could not expand the high school graduate market for the Marine Corps.

Youth Unemployment Rate

The national unemployment rate adjusted for youth ages 16-21 is the single most significant variable for the high school group when allowed to enter by itself. The elasticities are generally larger than for other Services for the high school graduate groups. The unemployment elasticities increase significantly when military pay is also included, and, generally, the highest R^2 value for the high school graduate groups when both variables are included.

For the non-high school graduate group, the elasticities are insignificant.

Marine Corps Bonus

The data would indicate that the effect of the bonus was insignificant in increasing any Marine Corps groups. The dummy variables that mark the start of the \$1500 and \$2500 bonuses do not enter the regression with any significance. This suggests again that pay is not a primary motivation for high school graduate Marine Corps enlistees. The insignificance of the bonus variable for non-high school graduates is puzzling since pay did appear to be significant for that group.

CONCLUSIONS

The Marine Corps time series analysis indicates a very small effect of any incentive program on high school graduate enlistments in the Marine Corps. Marine Corps high school graduate volunteer enlistments have not appreciably increased during the time period from CY71 to CY74. The results would indicate that increased pay is not a major motivator for high school graduate Marine Corps enlistments. The results for the non-high school group are in sharp contrast to the high school group. Additional pay and recruiting have caused significant increases in non-high school graduate Marine Corps volunteer enlistments. Recruiting emphasis may explain part of the difference. The difference is particularly disturbing in view of the current Congressional quota for 51 percent high school graduates. The Marine Corps will have a shortfall of high school graduates. The analysis here would suggest that increasing high school graduate enlistments may be difficult.

Chapter 6

ARMY TIME SERIES REGRESSION ANALYSIS

A regression analysis was performed on Army male non-prior service volunteer enlistments. The analysis involved program, policy and environmental variables that were in effect during the CY71 to CY73 period. The population groups studies are listed below:

- o Mental Category I-III high school graduates.
- o Mental Category I-IV high school graduates.
- o Mental Category I-III non-high school graduates.

Table 80 gives the standard deviation and mean values of the variables used in the analysis. The model for the time series analysis is given in App C, while the actual data and data descriptions are given in App D. Table 81 gives the correlation matrix for the variables used in the analysis. Regression results are given in Tables 82-87.

REGRESSION STRATEGY

Table 81 shows that the military pay variable is highly correlated with the recruiting variable, option variable and \$1500 bonus variable. Other significant intercorrelations appear between the \$1500 bonus variable and the unemployment and option variables, and between the unemployment and option variables. Estimates of elasticities and program effectiveness are made from a series of regression runs which include variables which do not have correlation coefficients above .7. The two variables with the highest correlation coefficients are recruiting and military pay. Since these two variables also have a correlation coefficient of .86, separate sets of runs were made with these variables. The elasticities for military pay and recruiting are probably somewhat overestimated.

OPTSTO -0	0.0000 0.0000 0.0000 0.0000	0.0000 0.0000 0.0000 0.0000	0.0000 0.0000 0.0000 0.0000	0.0000 0.0000 0.0000 0.0000	0.0000 0.0000 0.0000 0.0000

Very good R^2 values could be obtained with Army data without use of the quota variable. This result would indicate that the three Army groups investigated were supply limited during the time period.

Military Pay Variable

Table 88 summarizes the elasticity measurements for the military/civilian pay variable. For all Army volunteer groups studies, the military/civilian pay variable was highly significant.

Table 88
ELASTICITY ESTIMATES FOR THE MILITARY PAY VARIABLE
FOR DIFFERENT ARMY MENTAL CATEGORY GROUPS

	Category I-III HS	Category I-IV HS	Category I-III NHS
Lower estimate	.55 ± .13	.67 ± .12	.79 ± .10
Upper estimate	.71 ± .10	.85 ± .11	.96 ± .11
Best estimate	.62 ± .12	.76 ± .12	.88 ± .11

The elasticity is higher for the less educated, lower mental category groups. These groups probably have less job opportunity and generally lower paying jobs than the more educated groups.

Recruiter Variable

Table 89 summarizes the elasticities for the recruiter variable. The recruiter variable was highly significant, having F values generally above 30 for most runs. The delayed recruiter variable, with delays of one or two months, generally was the most significant.

Table 89
ELASTICITY ESTIMATES FOR THE RECRUITING VARIABLE
FOR DIFFERENT ARMY MENTAL CATEGORY GROUPS

	Category I-III HS	Category I-IV HS	Category I-III NHS
Lower estimate	.31 ± .06	.37 ± .07	.47 ± .06
Upper estimate	.46 ± .06	.51 ± .08	.57 ± .06
Best estimate	.38 ± .07	.44 ± .08	.52 ± .06

Again, the elasticities are larger for the lower mental category, less educated groups. These groups are probably easier for the recruiter to enlist than are the more highly educated groups.

Bonus Variables

Table 90 summarizes the results of the time series analysis for the dummy \$1500 and \$2500 bonus variables. The variables were simply zero-one variables making the offering of the \$1500 bonus and the \$1000 increment in the bonus.

Table 90
SEASONALLY ADJUSTED MONTHLY ESTIMATES OF INCREASES
DUE TO THE \$1500 AND \$2500 BONUSES

	Category I-III HS	Category I-IV HS	Category I-III NHS
<u>\$1500 Bonus</u>			
Lower estimate	0	0	0
Upper estimate	158 ± 154	0	160 ± 189
Best estimate	78 ± 78	0	80 ± 80
<u>\$1000 Increment</u>			
Lower estimate	285 ± 200	0	-
Upper estimate	0	663 ± 314	-
Best estimate	140 ± 140	330 ± 330	-

The bonus variables generally either did not enter the regressions or entered with very weak significance with F values generally less than 1. The data in Table 90 generally show small monthly increases of the order of only a few hundred at most from the bonus. The data would suggest that the \$1500 bonus was generally less significant and increased volunteers less than the \$1000 increment. The measurement of the bonus effect by time series methods is difficult for several reasons. The \$1500 bonus variable is highly correlated with the pay variable, option variable and unemployment. The size of the effect expected is small so that a significant difference in enlistment is hard to separate from the noise level. Generally, the results would suggest that the bonus increase

did increase monthly volunteers on the order of a few hundred; however, the analysis would tend to eliminate gains larger than a few hundred per month.

Print Media Variable

Table 91 summarizes the elasticities measured for print media.

Table 91
ELASTICITY ESTIMATES FOR THE PRINT MEDIA VARIABLE
FOR DIFFERENT ARMY MENTAL CATEGORY GROUPS

	Category I-III HS	Category I-IV HS	Category I-III NHS
Lower estimate	0	0	0
Upper estimate	.06 ± .04	.04 ± .04	.16 ± .04
Best estimate	.03 ± .03	.02 ± .02	.08 ± .08

The print media variable generally did not enter the regression or was weakly significant in the case of the high school graduate groups. The variable entered with greater significance for the non-high school graduate group. The size of the expected effect of advertising is generally small in terms of the additional number of enlistments. However, again the measurements serve to put some bounds on the effects of advertising.

Paid TV Variable

Table 92 summarizes the measurements of the effects of the paid TV-radio campaign. The campaign was in effect prior to the pay raise and, therefore, extrapolation of the effects to a future campaign are probably not warranted.

Table 92
SEASONALLY ADJUSTED MONTHLY INCREASES PER ADVERTISEMENT
DUE TO THE PAID TV-RADIO CAMPAIGN

	Category I-III HS	Category I-IV HS	Category I-III NHS
Lower estimate	7 ± 5	7 ± 8	6 ± 5
Upper estimate	10 ± 5	13 ± 7	12 ± 5
Best estimate	9 ± 5	10 ± 7	9 ± 5

The paid TV campaign variable entered each regression at an F value of between 1 and 3. The variable used in the analysis was the number of additional volunteer enlistments per advertisement.

Unemployment Variable

Table 93 summarizes the elasticities for the unemployment variable.

Table 93
ELASTICITY ESTIMATES FOR THE UNEMPLOYMENT VARIABLE
FOR DIFFERENT ARMY MENTAL CATEGORY GROUPS

	Category I-III HS	Category I-IV HS	Category I-III NHS
Lower estimate	.47 ± .15	.64 ± .16	-.70 ± .17
Upper estimate	.55 ± .17	.92 ± .22	-.90 ± .15
Best estimate	.51 ± .16	.78 ± .19	-.80 ± .16

The unemployment variable is significant for all groups with high F values. The elasticities are positive for the high school graduate groups and negative for the non-high school graduate groups. Generally, the results do not agree with other values from cross-sectional or time series measurements. One possible explanation for the negative coefficient in the non-high school graduate group is that the Service represents such a strong inducement for the unemployed non-high school graduate that a significant portion of the total number of unemployed youth in this group enlisted so that the unemployment rate actually went down.

CONCLUSIONS

Good fits for all Army groups tested were obtained through use of incentive variables only. The value of R^2 for the groups was usually greater than .7. The three groups fitted were Category I-III high school graduates, Category I-IV high school graduates and Category I-III non-high school graduates, and all groups display strong effects due to incentive programs. The good fits with incentive variables is an indication of supply limitation for all groups. The two most significant variables for the high school graduate groups were recruiting and military pay. Smaller effects were measured for the bonus, print media and paid TV.

Chapter 7

ANALYSIS OF THE COST EFFECTIVENESS OF THE COMBAT ARMS BONUS BASED ON AFEES SURVEY DATA

PURPOSE

This paper provides an analysis of the relative impact of the change in bonus payments and eligibility policies on the supply of high school graduates to the combat arms field for the Army and the Marine Corps. One specific purpose is to attempt to determine whether the increase in the bonus from \$1500 to \$2500 has resulted in a "cost effective" improvement in the supply of bonus eligible (high school graduates, Mental Category I-III) personnel to both the Army and the Marine Corps.

BACKGROUND

Assessments of the possible expanded supply of bonus eligibles to a Service offering the cash incentive are believed to come from two sources. First, absolute increases to the overall supply pool due to a change in the ratio of military to civilian income opportunities, and second, applicant cross-flows between the Services stimulated by the wage differential created by the Service(s) offering the bonus.

Another phenomenon worthy of a defense manager's attention is the effect the bonus has in channeling the flow of applicants with an enlistment affinity to one Service to occupations where manpower demands exceed the normal supply.

From the period June 1972 through April 1973, a \$1500 bonus was offered to applicants who enlisted in the combat arms field for a four-year period. The bonus was available to both the Army and Marine Corps, although the Army was the principal user of the bonus option. In May 1973, the bonus amount was increased to \$2500 and offered only to high school graduates in Mental Category I-III. It was also extended on a

test basis to certain technical skills, primarily in missile repair and operator MOSs, but this was terminated after two months, on June 30, 1973.

The number of bonus recipients from July 1972 through April 1973 averaged about 2000 per month or 70 percent of combat arms enlistments for the Army and 500 per month or about 95 percent of combat arms enlistments for the Marine Corps. The increase in payment and change in bonus eligibility standards imposed in May 1973 resulted in a substantial drop in both the number and percentage of bonus recipients from the combat arms enlistment pool. For the period July 1972 through March 1974, the Army averaged 1000 bonus recipients per month or 38 percent of their combat arms enlistments, while the Marine Corps averaged 90 per month or 50 percent of their combat arms enlistments.*

RESULTS

The criterion established for judging the cost effectiveness of the current bonus plan is to compare AFEES survey results for high school graduates during the periods in which the \$1500 and \$2500 bonuses were offered and draw inferences from the survey data on possible manpower supply effects due to the increase in bonus payments.

Data from the AFEES survey conducted during a period in which the \$1500 bonus was offered to both high school and non-high school graduates alike, reveal that about 14 percent of those claiming to be high school graduates and accepting the bonus option indicated they would not have entered the Army at all, while the corresponding figure for the Marine Corps was 5 percent.

Table 94 displays the cumulative results of the AFEES surveys conducted during the period June through October 1972. The cumulative results for a similar question on the revised AFEES survey conducted during the period July through October 1973 are shown in Table 95. In both Services there are significant changes in the response patterns between the two survey periods. If the survey results are valid and

* These figures only represent those who enlist in the combat arms field. They exclude those general enlistments which enter with no MOS guarantee and are assigned to a combat arms specialty. Both Services, particularly the Marine Corps, have made liberal use of this pool in filling their combat arms needs.

Table 94

CUMULATIVE RESULTS OF AFEES SURVEYS,
JUNE THROUGH OCTOBER 1972

Question #66 - If the \$1500 bonus had not been offered, what would you have done?

Base - Those who reported to be high school graduates and accepted the \$1500 bonus option.

	High school graduates			
	Army bonus		USMC bonus	
	f	%	f	%
I would have:				
A. Enlisted in Army	1002	85.9	11	.9
B. Enlisted in Navy	34	2.9	15	1.3
C. Enlisted in Marine Corps	25	2.1	1140	95.4
D. Enlisted in Air Force	31	2.7	10	.8
E. Not enlisted at all	75	6.4	19	1.6
Total	1167	100.0	1195	100.0

Table 95

CUMULATIVE RESULTS OF AFEES SURVEYS,
JULY THROUGH OCTOBER 1973

Question #50 - If there were no cash enlistment bonus in Army and Marine Corps, what would you have done?

Base - Those who reported to be high school graduates and accepted the bonus option.

	High school graduates			
	Army bonus		USMC bonus	
	f	%	f	%
A. Not signed up at all	195	11.7	50	7.6
Would have signed up for:				
B. Army, same job	879	52.8	43	6.5
C. Army, other job	496	29.8	49	7.5
D. Navy	36	2.2	22	3.3
E. Marine Corps, same job	7	.4	333	50.8
F. Marine Corps, other job	7	.4	150	22.9
G. Air Force	44	2.7	9	1.4
Total	1664	100.0	656	100.0

representative of the high school graduate population who enlisted and accepted the bonus option, the following inferences can be drawn:

1. Both Services experienced a sizeable expansion in the relative share of the high school graduate bonus population who would not have enlisted in any Service without the bonus.

o For the Army, the proportion increased from 6.4 percent of the group when the \$1500 bonus was in effect to 11.7 percent with the \$2500 bonus in effect

o For the Marine Corps, the effect was relatively more dramatic, rising from 1.6 percent to 7.6 percent of the group.

2. The expansion in new supply of high school graduates (Mental Category I-III) previously unavailable to the Army and Marine Corps based upon the survey results with the \$2500 bonus in effect is averaging about 1800 annually for the Army and 265 annually for the Marine Corps.

3. The degree and direction of the intra-Service flow of applicants stimulated by the increase in the bonus has not been the same for the Army and Marine Corps.

o 7.7 percent of the Army high school graduate (Mental Category I-III) bonus recipients, or about 580 annually, were drawn away from the other Services when the \$1500 bonus was in effect. With the \$2500 bonus in effect, the survey results show that a slightly smaller proportion, 5.7 percent or about 590 annually, were drawn away from the other Services.

o The Marine Corps was unable to provide data on the actual number of high school graduate bonus recipients while the \$1500 bonus was in effect. But 3.0 percent of the survey group claiming to be high school graduate bonus recipients were drawn away from the other Services while the \$1500 bonus was in effect and 18.7 percent with the \$2500 bonus in effect or about 185 annually. If one speculated that 40 percent of Marine Corps \$1500 bonus recipients were high school graduates (Mental Category I-III), the survey results infer that about 72 bonus recipients were drawn away annually from the other Services.

4. Slightly more than half of the high school graduate \$2500 bonus recipients for both Services indicated they would have entered that

speciality and Service even without the bonus. No comparable data are available from the earlier AFEES survey while the \$1500 bonus was in effect.

5. Based upon the criteria established for payment of the \$2500 bonus and the results of the AFEES survey, the current option is not as cost-effective as the \$1500 bonus plan for the Army.

o The average cost per additional high school graduate (Mental Category I-III) man-year obtained under the \$1500 bonus option was \$1054 and \$1642 under the \$2500 option for the Army. The calculations are as follow:

\$1054 Calculation

Army high school graduate, Mental Category I-III bonus recipients for the period July 1972 through April 1973 was 5640. Of the 5640, 85.9 percent said they would have entered the Army without the bonus, but they did provide one additional man-year by accepting the four-year bonus option.

$$5640 \times .859 \times 1 = 4845 \text{ man-years}$$

The remainder, or 14.1 percent, are classed as new supply, contributing four man-years each since they claimed they would not have entered the Army without the \$1500 bonus.

$$5640 \times .141 \times 4 = 3180 \text{ man-years}$$

Total new man-years acquired due to the bonus is $(4845 + 3180) = 8025$. The total bonus investment is $(5640 \times \$1500) = \8.46 million, for an average cost per additional man-year of $(\$8.46\text{M}/8025) = \1054 . The cost per additional high school graduate enlistee is $(\$8.46\text{M})/(5640 \times .141) = \$10,600$.

\$1642 Calculation

Army high school graduate, Mental Category I-III bonus recipients for the period July 1973 through March 1974 was 7733. Of the 7733, 82.6 percent said they would have entered the Army without the bonus, but did provide one additional man-year by accepting the four-year option.

$$7733 \times .826 \times 1 = 6387 \text{ man years}$$

The remainder, or 17.4 percent, are classed as new supply contributing four man-years each since they claimed they would not have entered the Army without the bonus

$$7733 \times .174 \times 4 = 5384 \text{ man-years}$$

The total new man-years acquired due to the \$2500 bonus is $(6387 + 5384) = 11,771$. The total bonus investment is $(7733 \times 2500) = \$19.33$ million for an average cost per new man-year of $(\$19.33\bar{M}/11,771) = \1642 . The cost per additional high school graduate enlistee is $(\$19.33\bar{M})/(7733 \times .174) = \$14,400$.

6. The opposite of observation #5 appears to be the case for the Marine Corps. The \$2500 bonus is more cost-effective under the current eligibility criteria than the \$1500 bonus.

o The average cost per additional high school graduate (Mental Category I-III) man-year obtained under the \$1500 bonus option was \$1982 and \$1677 under the \$2500 option. The calculations are as follows:

\$1982 Calculation

Forty percent of the 5018 total Marine Corps bonus recipients for the period July 1972 through April 1973 are believed to be high school graduates, Mental Category I-III.

$5018 \times .40 = 2007$ high school graduate, Mental Category I-III
bonus recipients

Of the 2007, 95.4 percent said they would have entered the Marine Corps without the bonus, but provided about .6 additional man-years by accepting the four-year option since average enlistments are currently running 3.4 years (as opposed to the Army's 3.0 years).

$2007 \times .954 \times .6 = 1148$ man-years

The remainder, 4.6 percent, are classed as new supply contributing four man-years each since they claimed they would not have entered the Army without the \$1500 bonus.

$2007 \times .046 \times 4 = 370$ man-years

Total new man-years acquired due to the bonus is $(1148 + 370) = 1518$ man-years. The total bonus investment $(2007 \times \$1500) = \3.01 million, for an average cost per additional man-year of $(\$3.01\bar{M}/1518) = \1982 . The cost per additional high school graduate enlistee is $(\$3.01\bar{M})/(2007 \times .046) = \$32,600$.

\$1677 Calculation

Marine Corps high school graduate, Mental Category I-III bonus recipients numbered 750 for the period July 1973 through March 1974.*

* The Marine Corps currently pays both a \$2500 and \$1500 bonus, the lower amount given to qualified high school graduates who are in Mental Category IIIB. No separate accounting of the number of \$1500 payments was available.

Of the 750, 73.7 percent said they would have entered the Marine Corps without the bonus, but did provide an additional .6 man-years by accepting the four-year option.

$$750 \times .737 \times .6 = 332 \text{ man-years}$$

The remainder, 26.3 percent, are classed as new supply, providing four additional man-year each, since they claimed they would not have entered without the bonus.

$$750 \times .263 \times 4 = 789 \text{ man-years}$$

Total new man-years acquired due to the bonus is $(332 + 789) = 1121$ man-years. The total bonus investment is $(750 \times \$2500) = \1.88 million for an average cost per additional man-year of $(\$1.88\text{M}/1121) = \1677 . The cost per additional high school graduate enlistee is $(\$1.88\text{M})/(750 \times .263) = \9500 .

7. One of the more interesting results is that the average cost per additional man-year acquired due to the \$2500 bonus is about equal for the Army (\$1642) and the Marine Corps (\$1677). The survey results show that the Marine Corps bonus recipients exhibited a stronger response to the higher payment than did their Army counterparts. This could partially be accounted for by the fact that the Marine Corps does not have as diverse an enlistment option strategy as the Army, making other Army options competitive with the current bonus.

8. The survey results also reveal that more than half of the \$2500 Marine Corps bonus recipients who claim they would not have enlisted without the bonus came from the Army. While the number is small (about 100 annually), a more aggressive recruiting effort by the Marine Corps, using the bonus, could lead to further losses to the Army.

SUMMARY

Table 96 summarizes the cost effectiveness measures derived from the AFEES survey data.

Table 96
 BONUS COST EFFECTIVENESS MEASURES FROM AFEEs DATA

	Army		Marine Corps	
	\$1500 bonus	\$2500 bonus	\$1500 bonus	\$2500 bonus
Cost per additional high school graduate man year	1,054	1,642	1,982	1,677
Cost per additional high school graduate	10,600	14,400	32,600	9,500

Chapter 8

COMPARISON OF ELASTICITIES FROM DIFFERENT MEASUREMENTS AND COST EFFECTIVENESS ANALYSIS

A definitive comparison of elasticities from different measurements is not valid since the measurements were made in different time periods and used different models and variables. These differences cause perturbations in the elasticity values which can be resolved only by a pooled time series and cross-sectional measurement over the entire time period. Currently there are significant data gaps that prevent such an approach. Nevertheless, comparison of current results from different models and time periods can reveal the extent of differences between measurements, and reveal relative trends among Services in program effectiveness.

COMPARISON OF RECRUITER ELASTICITY MEASUREMENTS

Table 97 summarizes the elasticities for the high school graduate groups from the time series and cross-sectional measurements. The high school group was chosen for comparison since this group has always been preferred by all Services and is the key to maintaining a quality force. Measurements were done on this group for both time series and cross-sectional analyses. For the Navy and Air Force, the Category I-III high school group measurements are quoted. The Category IV high school group is demand limited for both Services and it is assumed here that the recruiter elasticity for this group would be the same as the Category I-III group if the Services did not limit entry for this group. The results of previous measurements are also given in Table 97 for comparison. The previous measurements have been made generally in Mental Category groups I-II or I-III rather than high school graduates.

Table 97

COMPARISON OF RECRUITING ELASTICITIES FROM DIFFERENT MEASUREMENTS

	Army	Navy	Marine Corps	Air Force
Cross-sectional 1972 data	-	.75 ± .15	.18 ± .14	.84 ± .11
Cross-sectional 1973 data	.28 ± .21	.64 ± .17	.27 ± .11	.69 ± .15
Time series (1971-1973)	.44 ± .08	.33 ± .10 ^a	.08 ± .11	.76 ± .25 ^a
Previous cross-sectional measurements (1970 data) ^b	.28 to .69	.59 to .62	.28 to .34	.60 to .62

^aMeasurements made on Category I-III high school groups.

^bMeasurements made on Category I-II, Category I-III groups.

Comparison of measurements for the Air Force shows good agreement among the measurements with a range of elasticities from .60 to .84. In all measurements, the Air Force elasticity is higher than all other Services. Comparison of the Marine Corps data shows fair agreement among measurements with a range of elasticities between .08 and .34. The Marine Corps elasticities are generally the lowest of the Services. The Navy measurements show good agreement among the cross-sectional measurements, but the time series estimate is significantly lower. Several possible problems were mentioned in conjunction with Navy time series measurements. One additional problem not mentioned in that section is that the enlistees in the Navy 2X6 program probably were not included in the time series measurements. Inclusion of these enlistees would increase the time series elasticities for the Navy. Navy elasticities generally are lower than Air Force elasticities but higher than those for the Army and Marine Corps. Comparison of the Army data shows good agreement between time series and recent cross-sectional measurements, but poorer agreement with past measurements. The elasticity range is between .28 and .69. The Army elasticities are generally higher than the Marine Corps but lower than the Air Force and Navy.

The recruiter elasticities are important parameters in allocating incentive budgets among Services. In determining FY75-FY79 budget levels,

the elasticities from the 1973 cross-sectional measurements should probably be chosen for estimation purposes. Several considerations lead to this selection. The 1973 data are the most recent and are the first that include almost all enlistees as volunteers. Estimates from these data thus incorporate the most recent youth attitudes. In addition, the recruiting elasticities from the cross-sectional measurements are probably more accurate than the time series measurements since the time series measurements have problems of multicollinearity, especially between the recruiting and military pay variables. The values of the elasticities for the 1973 measurements are also in general agreement with prior measurements.

Using the results of the 1973 cross-sectional measurements, the number of additional high school graduates per additional recruiter can be calculated using the mean value of recruiters and enlistees for 1973. The results of this computation are given in Table 98.

Table 98
COMPARISON OF MARGINAL ANNUAL
PRODUCTIVITY OF SERVICE RECRUITERS

Service	Annual marginal productivity ^a
Air Force	22 ± 5
Navy	9 ± 2
Army	4 ± 3
Marine Corps	2.5 ± 1

^aAdditional high school graduates per year per additional production recruiter.

The data show a marked and significant difference in the ability of recruiters from the Services to recruit additional high school graduates. It is interesting to compare these data with youth preference data from the Gilbert Youth Survey as well as with actual FY74 results. Table 99 shows the Service of first preference for high school seniors who express some likelihood of enlisting. Table 100 shows a comparison of predictions from the Gilbert Youth Survey, the recruiter elasticity

Table 99

FIRST SERVICE PREFERENCE^a FOR HIGH SCHOOL SENIORS INDICATING LIKELIHOOD OF ENLISTMENT^b

Table 100

COMPARISON OF PERCENTAGE OF HIGH SCHOOL ENLISTMENTS EXPECTED IN EACH SERVICE FROM GILBERT YOUTH SURVEY, REGRESSION MEASUREMENTS AND ACTUAL FY74 DATA

Service	Gilbert Youth	Regressions	FY74 data
Army	25	11	37
Navy	26	24	25
Marine Corps	15	7	11
Air Force	34	59	27

estimates and FY74 results as to the relative percentage distribution of 100 high school graduate enlistees entering the service. The first column shows a prediction of the relative preference of youth as measured by the Gilbert Youth Survey. The second column is a prediction of the relative success of a recruiter from each Service in enlisting people as derived from the elasticity estimates. The third column shows the distribution of high school graduates in FY74. The data help bring into focus the relatively high marginal productivity of the Air Force recruiter during the FY71-FY73 time period. The data show that while 34 percent of high school seniors who express interest in the Services prefer the Air Force, the Air Force needs to recruit only 27 percent of high school graduates entering the Services. This would indicate a queue exists. It is thus very easy for additional Air Force recruiters to enlist extra people. The very high productivity of recruiters can probably be attributed to the existence of a queue of people; that is, each Air Force recruiter who goes out finds it fairly easy, in comparison with other Service recruiters, to find potential Air Force recruits because of the high youth preference and low requirements of the Air Force. This high Air Force productivity can also be explained by the fact that the Air Force can focus on high school graduates since they need recruit only a small number of non-high school graduates, whereas other Services have to spend substantially more time recruiting and enlisting non-high school graduates.

The Marine Corps data suggest that Marine Corps recruiting performance is relatively poor with respect to other Services. The data indicate that 15 percent of high school seniors who express interest in the Service prefer the Marine Corps, while the actual performance indicates that the Marine Corps obtains only 11 percent. The Marine Corps recruiting effort is thus not able to maintain their competitive edge with those persons who express interest in joining. The Marine Corps marginal productivity of recruiters is the lowest of any Service. One explanation of this may be the absence of a paid advertising campaign by the Marine Corps. Advertising provides many leads for recruiters of the other Services.

The Navy data suggest that they are able to maintain their share of the youth market, while the Army data indicate that they are able to enlist significantly more high school graduates than express first preference for the Army. While only 25 percent of Army enlistees express interest in the Army as first preference, 37 percent of high school graduates chose the Army in FY74. The difference in marginal productivity between the Navy and Army could probably be attributed to the larger number of recruiters the Army has in the field. Another explanation is that Army recruiters have to enlist almost an equal number of non-high school graduates so they cannot focus on the high school market to the extent Navy and Air Force recruiters can.

The cost per additional high school graduate for recruiting can be calculated from the data in Table 98 if the marginal annual cost of placing an additional recruiter on production is known. Appendix F contains the recruiting cost data collected from the Services. The data show variations among the Services. Part of the difference can be ascribed to different methods of calculating costs used by the recruiters. For instance, the Air Force included total training costs of a man to the time of recruiting duty. GRC has decided to use an average annual cost of \$30,000 for all Services until more information can be obtained about cost differentials. These cost differences are much smaller in magnitude than the differences in recruiter productivity so the uncertainty is not appreciably increased by using average cost. Table 101 gives the additional cost per high school graduate using the data from Table 98 and a cost of \$30,000. The data show wide variation in the cost of increasing the high school graduate supply of each Service.

Table 101
COST OF OBTAINING ONE ADDITIONAL HIGH SCHOOL GRADUATE
ENLISTMENT BY ADDITIONAL PRODUCTION RECRUITERS

Service	Cost
Air Force	1400 ± 300
Navy	3300 ± 700
Army	7500 ± 5600
Marine Corps	12000 ± 4800

COMPARISON OF MILITARY PAY ELASTICITIES

Table 102 gives the results of the time series and cross sectional measurements. The results show a great deal of variation in elasticity estimates. Causes of variation include different methods of defining pay variables, inclusion of different variables in the models, different model forms and different time periods. However, there are other reasons why the pay variable should show increased sensitivity to model and variable variation. Prior to 1972, the pay of first-term personnel was extremely low compared to civilian wages. Most enlistees entering the Services were motivated by draft pressure or non-monetary incentives. Changes in military pay at these lower rates would influence only a small portion of the youth. Measurements under these conditions are likely to be extremely unstable. In addition, most measurements on data prior to 1972 were cross-sectional. Pay differentials existed only for civilian wages. The pay differentials across different parts of the country were only about 10 or 15 percent. These pay elasticity measurements were dependent on relatively small differences in civilian wages, not military wages, thus making the results again particularly sensitive to the other variables included in the model. Measurements made during and after the period of the major pay raise in 1971 should provide the best measurements of pay elasticity. The base pay of incoming personnel was doubled so that the pay was competitive with wages in civilian society. The cross-sectional measurements after the pay raise suffer from the same handicap as before, namely that only relatively small differences in civilian wages exist across the country. On the other hand, the conditions for the time series measurements are good in that a substantial change in pay was made in a short period of time. The only problem with the time series measurements is that the pay is correlated with the recruiter variable. However, a good upper limit on pay elasticity can be obtained by running the variable by itself. The results from the time series measurements appear more reasonable than other measurements since all elasticities are positive. For the purpose of calculating cost effectiveness measures, the results of the time series analysis will be chosen. The discrepancies in the measurements can be reconciled by a pooled time series cross-sectional measurement.

Table 102
SUMMARY OF MILITARY/CIVILIAN PAY ELASTICITIES FOR HIGH SCHOOL GRADUATES

	Army	Navy	Marine Corps	Air Force
Cross-sectional 1972	.60 ± .28	-.86 ± .28	-	-
Cross-sectional 1973	.65 ± .28	-.19 ± .26	-.31 ± .37	.23 ± .22
Time series 1971-1973	.76 ± .12	.44 ± .13 ^a	.15 ± .08 ^a	.53 ± .13
Previous measurements ^b	-.79 to 1.77	-.17 to .82	-.12 to .55	.55 to 2.23

^aResults quoted are for Category I-III high school graduates only due to Category IV policy constraints.

^bResults generally are for Category I-II or Category I-III groups.

The cost effectiveness of pay for attracting additional high school graduate enlistments can be calculated using the time series elasticities from Table 102 and cost data. Table 103 shows the impact on high school graduate enlistments of a 10 percent raise in regular military compensation (RMC), holding civilian wages constant.

Table 103
IMPACT OF A 10 PERCENT INCREASE IN THE RATIO OF MILITARY/CIVILIAN PAY

	Army	Navy	Marine Corps	Air Force
FY74 male diploma high school graduates (000)	77	52	23	56
Pay elasticities	.76	.41	.20	.53
Effect of 10 percent pay raise (000)	+5.9	+2.1	+0.5	+3.0

While the previous table displayed the responsiveness of a change in the military/civilian pay ratio, the cost of achieving such an enlistment change was not shown. To derive a cost-effectiveness measurement, the dollar value of a pay raise must also be computed. Average RMC will be used since the regression variable used RMS pay for an E1 as the measure of military compensation. This appears to be a reasonable assumption since the comparability pay gap between the first-term and career force has been closed by the pay raise of November 1971. Only across-the-board percentage pay increases would now be provided.

Using average RMC pay rates for FY75 and pay grade distributions supplied in the Service POMs, a 10 percent pay raise for the enlisted force only for all Services would cost approximately \$1.48 billion and, based on the results shown in Table 104, 11,500 more male diploma high school graduates could be obtained. That results in a marginal cost of \$128,700 per high school graduate. Table 104 summarizes the cost effectiveness measures. It is an all too obvious fact that raising basic pay to attract additional NPS volunteers is the least cost effective of any of the programs measured by GRC. Thus, a pay raise is a very ineffective method of increasing NPS enlistments since this raise must be provided to

all military members so that pay equality among the Services and pay differentials between grades are preserved. This substantially reduces the cost effectiveness of pay raises to acquire more NPS enlistments.

Table 104
 PAY INCREASE COST EFFECTIVENESS MEASUREMENTS
 FOR MALE DIPLOMA HIGH SCHOOL GRADUATES

	Army	Navy	Marine Corps	Air Force
Marginal cost per male diploma high school graduate	\$91,000	\$185,000	\$268,000	\$140,000
Male diploma high school per additional \$1 million	11.0	5.4	3.7	7.1

COMPARISON OF UNEMPLOYMENT MEASUREMENTS

Table 105 summarizes the unemployment elasticity measurements from this report and previous measurements. The results show better agreement than the pay elasticities, but poorer agreement than the recruiter elasticities. Unemployment is generally a weaker variable in both time series and cross-sectional measurements and wider variations in elasticities are to be expected between model specifications. For the Army, the time series measurement differs significantly from the cross-sectional measurements. In general, the cross-sectional measurements are more reliable since the time series unemployment variable is collinear to a higher degree with other variables. The cross-sectional measurements for the Army are in fair agreement and show elasticities ranging from $-.12$ to $.41$ with best estimate at around $.1$ to $.2$. The Navy cross-sectional measurements show higher elasticities than previous measurements and give unemployment elasticity best estimates around $.2$. The Marine Corps data show fair agreement with best estimates from recent data of negligible elasticity. The Air Force data show fair agreement with elasticities of around $.2$ to $.3$.

ADVERTISING RESULTS

Table 106 summarizes the cost effectiveness results of the advertising measurements. The elasticities of the advertising measurements were

Table 105
SUMMARY OF UNEMPLOYMENT ELASTICITIES FOR HIGH SCHOOL GRADUATES

	Army	Navy	Marine Corps	Air Force
Cross-sectional 1972	.23 ± .13	.15 ± .13	.11 ± .14	0
Cross-sectional 1973	0	.23 ± .12	-.08 ± .15	.17 ± .09
Time series 1971-1973	.78 ± .19	-	.29 ± .12 ^a	.30 ± .17 ^a
Previous measurements ^b	-.12 to .41	-.04 to .02	.07 to .23	.22 to .34

^aResults from Category I-III high school graduates due to policy constraints on Category IV high school graduates.

^bResults from measurements on Category I-II or Category I-III groups.

taken from Tables 53 and 91, and average values of variables from Tables 43 and 80 in order to arrive at the annual marginal productivity of additional print media insertions given in Table 106. GRC has not obtained detailed advertising cost data. An estimate of \$27,000 per print media insertion is based on Army advertising data as estimated from the FY75 advertising plan. The cost includes direct cost of insertions plus production and overhead costs. Individual insertions vary widely in cost; however, it is thought that this cost estimate is accurate for an average cost across all magazines. The data again show that the Air Force program is able to attract additional recruits at significantly less cost than the Army.

Table 106
ADVERTISING COST EFFECTIVENESS RESULTS

	Army	Navy	Marine Corps	Air Force
Annual marginal productivity ^a	3 ± 3	-	-	11 ± 5
Marginal annual cost	27,000	-	-	27,000
Cost per additional high school graduate	9000 ± 9000	-	-	2500 ± 1100

^aAdditional high school graduates per national media insertion.

The advertising measurements have more uncertainty and sensitivity than other measurements for reasons which include:

1. The effect of advertising is small with respect to other programs (signal is weak).
2. Only time series data are available.
3. Cost data are currently more uncertain.

OVERALL COMPARISON OF COST EFFECTIVENESS RESULTS

Table 107 summarizes the cost effectiveness results from the best measurements. The data show that the Army unit canvasser program is the most cost effective of all enlistment programs. For the Army, it is by far the most cost effective program. The Army results show the advertising

Table 107

SUMMARY OF COST EFFECTIVENESS RESULTS^a

	Army	Navy	Marine Corps	Air Force
Pay	91,000 ± 14,000	185,000 ± 55,000	268,000 ± 140,000	140,000 ± 34,000
\$1500 bonus	10,600 ^b		32,600 ^b	
\$2500 bonus	14,400 ^b		9,500 ^b	
Advertising	9,000 ± 9,000	— ^c	— ^d	2,500 ± 1,100
Regular recruiters	7,500 ± 5,600	3,300 ± 700	12,000 ± 4,800	1,400 ± 300
Canvassers	900 ± 300 ^e			

^aMeasurement is marginal cost of an additional high school graduate enlistment.

^bMarginal cost was estimated from survey data and no error estimates could be made.

^cThe Navy did not provide advertising data.

^dThe Marine Corps had no paid print media insertions.

^eRobert Babiskin, *et al.*, "Cost Effectiveness of Army Recruiting and Canvasser Programs during Fiscal Year 1974," OAD-CR-51, General Research Corporation, McLean, Virginia, to be published.

and regular recruiter budgets to be in rough balance, but clearly indicate the need to maintain the canvasser program at a high level, even if funding has to come from advertising or regular recruiter budgets. For the Navy, if we assume a canvasser program would be as productive as the Army's, and that the Navy's advertising is as productive as the Air Force's, the data would show the need for an expanded recruiter assistant/canvasser program. Currently there would exist a rough balance between Navy advertising and recruiting resources. The Marine Corps data show the cost of additional personnel to be by far the highest of any Service, and a need to initiate a canvasser program as well as determine the reason for low recruiter productivity. For the Air Force, the data show that current advertising and recruiting expenditures are not in balance. The cost effectiveness of Air Force programs is the highest of any Service primarily because of the increased propensity of youth to join the Air Force.

Appendix A
PAY INDEX

The pay index for each state is defined as the ratio of the military wage to the civilian wage. A separate relative wage was constructed for 17-18 year olds and 19-21 year olds. The military wage is assumed to be equal for each state and is defined as the total 3-year pay based on the average RMC pay which includes base pay, quarters and subsistence allowances, and tax advantages.* The RMC pay was discounted at 30 percent, and the following data** on average time in grade were used.

<u>Promotion to grade</u>	<u>Average time in service</u>
E-2	3 months
E-3	6 months
E-4	14.5 months
E-5	23 months
E-6	excess of 6 years

The civilian wage was constructed from data taken from the Consumer Income Series P-60, No. 85, December 1972, US Department of Commerce. This series publishes average incomes for ages 16-19 and 20-24. A non-linear interpolation method was used to estimate the average incomes for 17-18 year olds and 19-21 year olds over a 3-year time horizon. The civilian pay also was discounted at 30 percent. The actual civilian wage used for each RMS was weighted by the relative pay received by individuals on manufacturing payrolls in the area. This method assumes that the income of 17-21 year olds is directly correlated with the manufacturing wage in each state.

* Source: LTC Arcari, OSD Compensation Study Group.

** Source: LTC Jacoby, Directorate of Military Personnel Policies, Promotions, Separations, and Transitions Division.

The formula for the pay index is given as:

$$W_i = X_i \left[\frac{Z_i}{\bar{Z}} \right] \quad i = 1, \dots, 47$$

where

W_i is the pay index in the i^{th} state

X_i is the average income for ages 17-18 or 19-21

Z_i is the average income of individuals on manufacturing payrolls
in the i^{th} state

\bar{Z} is the average income of individuals on manufacturing payrolls
in all states

Appendix B
WEIGHTING SYSTEM FOR UNEMPLOYMENT RATES

Since unemployment rates were not directly available for the individual groups for high school graduates, non-high school graduates, Category I-II and Category I-III, a weighted index based on the actual distributions of volunteers by age for 1972 and 1973 was used for these categories. The weighted series was constructed according to the formula below:

$$X_{ijk} = \%X_{ij}(18) + \%X_{ij}(21) \quad \begin{array}{l} i = 1,2 \\ j = 1,2,3,4,5 \\ k = 1,2,3,4 \end{array}$$

where

i is the year, 1972 or 1973

j is the Service (Army, Air Force, etc.)

k is the volunteer category (1 = high school, 2 = non-high school, 3 = Category I-II, and 4 = Category I-III)

The formula defines unemployment for each of the four volunteer categories as being equal to the percentage in the group that are 17-18 year olds times the unemployment rate for 17-18 year olds plus the percentage in the group that are 19-21 year olds times the unemployment rate for 19-21 year olds.

The following equations were used:

Army

1972

$$X = .46X(18) + .54X(21) \text{ high school}$$

$$X = .77X(18) + .23X(21) \text{ non-high school}$$

$$X = .59X(18) + .41X(21) \text{ Category I-II}$$

$$X = .63X(18) + .37X(21) \text{ Category I-III}$$

1973

- X = .50X(18) + .50X(21) high school
- X = .70X(18) + .30X(21) non-high school
- X = .58X(18) + .42X(21) Category I-II
- X = .61X(18) + .39X(21) Category I-III

Air Force

1972

- X = .69X(18) + .31X(21) non-high school
- X = .52X(18) + .48X(21) Category I-II
- X = .53X(18) + .47X(21) Category I-III

1973

- X = .51X(18) + .49X(21) high school
- X = .74X(18) + .26X(21) non-high school
- X = .55X(18) + .45X(21) Category I-II
- X = .56X(18) + .44X(21) Category I-III

Marine Corps

1972

- X = .51X(18) + .49X(21) high school
- X = .74X(18) + .26X(21) non-high school
- X = .64X(18) + .36X(21) Category I-II
- X = .67X(18) + .33X(21) Category I-III

1973

- X = .56X(18) + .44X(21) high school
- X = .80X(18) + .20X(21) non-high school
- X = .71X(18) + .29X(21) Category I-II
- X = .72X(18) + .28X(21) Category I-III

Navy

1972

- X = .58X(18) + .42X(21) high school
- X = .80X(18) + .20X(21) non-high school
- X = .62X(18) + .38X(21) Category I-II
- X = .65X(18) + .35X(21) Category I-III

1973

$$X = .59X(18) + .41X(21) \text{ high school}$$

$$X = .85X(18) + .15X(21) \text{ non-high school}$$

$$X = .61X(18) + .39X(21) \text{ Category I-II}$$

$$X = .67X(18) + .33X(21) \text{ Category I-III}$$

DOD Total

1972

$$X = .51X(18) + .49X(21) \text{ high school}$$

$$X = .76X(18) + .24X(21) \text{ non-high school}$$

$$X = .58X(18) + .42X(21) \text{ Category I-II}$$

$$X = .62X(18) + .38X(21) \text{ Category I-III}$$

1973

$$X = .53X(18) + .47X(21) \text{ high school}$$

$$X = .74X(18) + .26X(21) \text{ non-high school}$$

$$X = .60X(18) + .40X(21) \text{ Category I-II}$$

$$X = .63X(18) + .37X(21) \text{ Category I-III}$$

Appendix C
TIME SERIES REGRESSION MODEL

The regression model used in this analysis differs from the standard linear model in that the seasonal dummy variables are multiplicative rather than additive. The regression model is:

$$y_i = \prod_{j=1}^{12} e^{\alpha_j \delta_{ij}} \left(\sum_{k=1}^N \beta_k X_{ik} + \beta_0 \right)$$

where

- y_i = monthly enlistments in month i
- δ_{ij} = 0, 1 variable, equals 1 if month i equals month j , zero otherwise
- e^{α_j} = monthly seasonal factor for month j
- X_{ik} = value of independent variable k for month i
- β_k = regression coefficient for variable k
- β_0 = regression constant

A nonlinear regression technique is used to solve for the coefficients $\beta_0, \beta_k, \beta_j$ simultaneously.

The variables y_i and X_{ik} used in the analysis are given in App D.

Appendix D
TIME SERIES DATA

This appendix contains the actual time series data collected for the analyses. A brief description of the data and source is given in each variable. An index of variables is given below:

This time series is the total 3-year pay based on the average RMC pay which includes base pay, quarters and subsistence allowances, and tax advantages.* The RMC pay was discounted at 30 percent, and the following data** on average time in grade were used.

Promotion to grade	Average time in service, months	
	1/1/70	1/9/73
E-2	3.0	3.0
E-3	6.0	7.0
E-4	14.5	15.7
E-5	23.0	27.1
E-6	72.0+	91.9

This time series is the ratio derived by GRC of military RMC for grade E-1 to the civilian average weekly wages for two industries — Wholesale and Retail Trade and Services. Source of RMC data is DCSPER, DAPE-MPE. The data on civilian average weekly earnings are the average for the two industries from the Department of Labor, BLS, monthly publication, "Employment and Earnings," Table C-2.

This time series is the number of Navy recruiters on production for each month. These data are derived by the Navy from the number of personnel who are canvasser qualified, about 10 percent of whom are engaged on non-production type activities such as supervisors, administration, advertising. Source of the data is LCDC S. W. Sigmund, Navy Recruiting Command.

This time series is the unemployment rate for 16-21 year old males. It is the percent of 16-21 year old unemployed males of the 16-21 year old male civilian labor force whose major activity was other. "Major activity: going to school" and "major activity: other" are terms used to describe whether the activity of young persons during the reference week (of the monthly survey) was primarily one of going to school or not. The source of the data is Table A-5 of the Bureau of Labor Statistics (BLS) monthly publication, "Employment and Earnings."

DESEASONALIZATION FACTORS FOR UNEMPL1
 SERIES ON TREND 1/70-9/73

DFCTUNMPL1	73	11	.9630
DFCTUNMPL1	73	12	1.0470

This variable is the series of seasonal adjustment factors developed by GRC through regression on trend from January 1970 to September 1973 (DFCTUNMPL1). These factors were used to create a deseasonalized unemployment variable for the 16-21 year old male, out-of-school labor force (DUNEMPL1).

OPTSTONAV	73	10	13.0000
OPTSTONAV	73	11	13.0000
OPTSTONAV	73	12	13.0000

This variable is the number of new separate options available to an incoming recruit to the Navy. Source of the data is LCDR S.W. Sigmund, Navy Recruiting Command.

TOTAL OPTIONS

This time series is the number of Category I, II, III Navy volunteers who are not diploma high school graduates as estimated by the GRC maximum method that includes 100 percent men without LSNs as volunteers. The data were derived from the GRC Data Bases by subtracting Category I, II, III Navy volunteers who are diploma high school graduates from Category I, II, III Navy volunteers.

CATEGORY IV NAVY VOLUNTEERS WHO ARE
HIGH SCHOOL GRADUATES

Appendix E
INTERPRETATION OF THE REGRESSION ANALYSIS REPORTS

This appendix provides an explanation of the computer program report used to display regression results in Chaps. 3-7. The report is a summary of the regression results for a subset of the analysis and describes the elements of each regression. An example of the report is shown in Table E-1.

The regression models derived by the nonlinear program are shown in Table E-1 and the number of regressions performed is indicated by the number of symbolic terms under the heading "DEPENDENT VARIABLES." In the example, results for eight regressions are displayed: the dependent variables* are N1HS, N2HS, N3HS and N4HS. The example report summarizes the effectiveness of several Service programs on Navy volunteer enlistments by separate mental category groups.

Symbols for the program variables in the analysis are listed in the first column at the left of the report under the heading "INDEP. VARIABLES AND MONTHLY SHIFTS." A shift of -n means that the variable represents a program lagged by n months in effect. In the example, there are ten independent variables: NQOT-DM, MILCIVPAY, DUNEMPL1(-2,-1,0), OPTSTONAV (-2,-1,0), BNS-HS and BNS-INC. Some or all of the independent variables were available for selection into each regression. The four-part unit entry for each independent variable indicates whether or not a variable was allowed to enter a regression and if so, the status of that variable at the end of the stepwise regression procedure.

* Time series variables are listed and described in App D.

Evaluative information about a regression is given in the Table E-1 output. The most important information is displayed in the row entitled "R-SQUARED" and in the independent variable unit entries. Values in the "R-SQUARED" row are squares of the multiple correlation coefficient for the regressions. These values are measures of the proportion of total variation in the data which are explained by the regression equation. Therefore, a regression for which R-SQUARED is .67 is assumed to have more predictive power as a model than one for which R-SQUARED is .36.

A unit entry for an independent variable listed in the report consists of four decimal values which provide the following information:

Line 1: The coefficient for this variable in the final regression. This field is zero whenever the variable did not appear in the final equation or was never allowed to enter the regression. In the first regression of the example, the equation given in linear form^{*} is

$$Y = .0137X_1 + 0.0X_2 + 104.01$$

where

Y = NLHS population group

X₁ = NQOT-DM program variable

X₂ = MILCIVPAY program variable

Note that the equation contains a constant value 104.01 -- the intercept value for the regression model. The constant term for each regression appears on the output directly below the R-SQUARED values.

Line 2: The standard error of estimates for this variable. This field is zero whenever the variable was not included in the final equation or was never allowed to enter the regression procedure.

Line 3: The F value for this variable at the end of the stepwise regression procedure. When the coefficient for this variable is nonzero,

*The exact form of the regression model for a population group Y is

$$Y_i = \prod_{j=1}^N e^{\alpha_j \delta_{ij}} \left(\sum_{k=1}^N \beta_k X_{ik} + \beta_0 \right)$$

where N is the number of independent variables in the model. See App C for further explanation of the terms in the model.

the F value denotes the significance of this variable in the regression. It is also used to test the hypothesis that the coefficient is zero for this variable. If the value in this field is "0.0000," the independent variable was not available for inclusion in the regression, i.e., the variable was not among the input variables to the regression procedure. When the coefficient of an independent variable in a regression is zero, the F value most often displays a small value. This shows that the variable would have been ineffectual or insignificant in the regression. When a variable does not appear in the final regression step, but a high F value is displayed, the variable was restricted because of the coefficient's positive or negative sign.

Line 4: The elasticity for this variable. The field is zero whenever the variable was not allowed in the regression or did not appear in the final step of the procedure. The elasticity measures the average percentage increase in the population variable due to a percentage increase in the independent variable. The elasticity for an independent variable in a regression model is computed as shown below.

$$\text{elasticity}_X = \beta(\bar{X}/\bar{Y})$$

where

X = independent variable

β = regression coefficient

\bar{X} = mean value of the independent variable X

\bar{Y} = mean value of the dependent or population variable Y

Other pertinent information on the report is given by the values in the row designated "ELAST.CONST." These values are computed such that when added to the sum of the elasticities of the independent variables in the regression, the result is unity. These elasticity constants may not be interpreted in the same manner as independent variable elasticities but are considered rather as "absorption" factors of the regressions.

Appendix F
ANALYSIS OF RECRUITER COSTS

The data on Table F-1 summarize the Services' responses to a GRC request for data on the average annual cost of fielding a production recruiter. The costs were divided into three major categories: initial investment costs, annual direct operating costs and annual overhead costs.

The first category is the initial investment required to add one more recruiter to the force. To some extent, it is also the cost of replacing one recruiter with another since recruiter training costs will be incurred both as the force is expanded and as normal personnel turnover occurs.

Initial investment costs range from a high of \$18,500 for the Air Force to as low as \$1,600 for the Navy. GRC believes the differences result from variations in cost accounting procedures and recruiter training methods of the Services. All Services, except the Air Force, show rather modest training costs. The cost of training an Air Force recruiter has recently increased from the \$10,000 figure displayed in Table F-1 to approximately \$11,000 in FY75. Unlike the other Services' training cost figures, the Air Force accumulates all costs associated with bringing an airman into the recruiter force. GRC has obtained a breakdown of those costs as shown in Table F-2.

Training costs for Air Force recruiter support personnel are also formulated in a similar manner. For the data that appear on Table F-3, GRC has elected to show only the costs associated with the recruiter training school so that such costs are more comparable with the other Services.

Table F-1

SERVICE-SUPPLIED PRODUCTION RECRUITER ANNUAL COST DATA

	Army	Navy	Marine Corps	Air Force	DOD average
Initial investment costs	<u>\$5,527</u>	<u>\$1,618</u>	<u>\$1,649</u>	<u>\$18,449</u>	<u>\$6,811</u>
Vehicle procurement ^a	1,826	0	0	0	0
Office equipment	850	150	231	1,114	586
Supplies	35	73	67	38	53
Recruiter training	1,854	1,395	1,351	10,041	3,660
Other personnel training	962	0	0	7,256	2,054
Annual direct operating costs	<u>20,050</u>	<u>20,254</u>	<u>22,100</u>	<u>29,130</u>	<u>22,884</u>
Office equipment replacement	85	119	108	220	133
Supplies	210	195	322	797	381
Recruiter replacement and training (refresher courses)	510	901	629	2,510	1,138
Other personnel replacement and training	160	0	0	1,814	494
Recruiter pay and allowances	11,300	10,595	9,779	10,462	10,534
Other personnel pay and allowances	7,785	8,444	11,262	13,327	10,204
Annual overhead costs	<u>4,082</u>	<u>1,493</u>	<u>3,640</u>	<u>5,002</u>	<u>5,682</u>
Vehicle operation and maintenance	819	1,016	1,260	1,677	1,020
Facility rental	1,650	0 ^b	1,717	1,816	1,295
Communications	914	306	415	1,434	3,069
Administrative travel and per diem	699	171	248	75	298
Total costs	<u>\$29,659</u>	<u>\$23,365</u>	<u>\$27,389</u>	<u>\$52,581</u>	<u>\$35,377</u>

^aAll Services are now leasing their sedans either commercially or through GSA.

^bThe Navy did not provide a cost for this element but it is possible that their rental expense is similar to the other Services.

Table F-3

GRC MODIFIED PRODUCTION RECRUITER COST ESTIMATES (FY75 DOLLARS)

	Army	Navy	Marine Corps	Air Force	DOD average
Initial investment costs	\$3,900	\$3,200	\$3,150	\$10,300	\$5,140
Vehicle procurement ^a	0	0	0	0	
Office equipment and supplies	600	600	600	600	600
Recruiter training (cost of courses) ^b	2,100 ^c	1,400	1,350	6,600 ^c	2,860
Other personnel training ^b	1,200 ^c	1,200 ^c	1,200 ^c	3,100 ^c	1,680
Annual recurring costs	<u>25,470</u>	<u>25,220</u>	<u>27,020</u>	<u>32,250</u>	<u>27,510</u>
Office equipment replacement and supplies	500	500	500	500	500
Recruiter replacement and training ^d	800	1,200	900	1,400	1,100
Other personnel replacement and training (refresher) ^e	400	200	200	800	400
Recruiter pay and allowances (RMC) ^f	11,600	11,600	10,700	11,600	11,400
Other personnel pay and allowances	8,000	8,500	11,000	13,000	10,100
Vehicle operation and maintenance	820	1,000	1,300	1,700	1,200
Facility rental	1,750	1,750	1,750	1,750	1,750
Communications	900	300	420	1,400	760
Administrative travel and per diem	700	170	250	100	300
Total costs	<u>\$29,370</u>	<u>\$28,420</u>	<u>\$30,170</u>	<u>\$42,550</u>	<u>\$32,650</u>

^aAssumes all vehicles leased either commercially or from GSA. Should include depreciation expenses as an off-set to procurement costs.

^bThe Air Force-supplied cost included basic training plus an allowance for OJT. This and certain other costs were removed to show cost of recruiter or support course only. The Army recruiter course cost revised based on latest Army (C) data for MOS OOE.

^cNot included in Service recruiting budgets.

^dIncludes \$300 per man at average PCS cost. Based on 20 percent annual turnover rate times a \$1500 average PCS cost.

^eIncludes \$200 per man as average PCS cost for other military personnel.

^fBased on average RMC for an E-6.5 average enlisted grade for all Services except USMC with an E-6.0 average grade.

Table F-2
AIR FORCE RECRUITER TRAINING COST

Cost component	Cost
Initial procurement and pre-technical training	\$2,428
Recruiter specialty training	6,558
Capital investment	768
On-the-job training	1,101
Leave and other costs	234
Total	\$11,089

Both the Army and the Air Force have formal training schools for their enlisted recruiters, while the Navy and Marine Corps do not. The higher overhead associated with operating a formal training school partially accounts for the difference in training costs among the Services. The Army's training costs, as displayed in Table F-1 are somewhat lower than the Air Force because only the costs incurred while in recruiter school are shown.* Information from the Army comptroller's office reveals that a cost comparable to the Air Force figure, to include basic training costs, is approximately \$4,500. It also should be pointed out that the costs associated with initially training Army and Air Force recruiters is not included in their respective recruiting budgets, while recruiter training costs for the Navy and Marine Corps are funded through their recruiting budgets. Based on the POM recruiting personnel data and training school cost data, the Army and Air Force are each spending between \$15-\$20 million annually on training of recruiting personnel which does not appear in their recruiting budgets.**

The second and third categories on Table F-1 represent the annual costs to sustain a recruiter once he is assigned to the field. After reviewing the data, GRC does not believe the break-down between direct operating costs and overhead costs is of any particular value, since it

* In addition, course lengths vary between the Services, with the Air Force running an 8-week course and the Army's lasting 5 weeks.

** This estimate excludes basic training costs and initial recruit procurement expenses.

not clear which cost elements (or portion thereof) should be identified with the activities of a recruiter and what elements are strictly administrative overhead that remain relatively fixed as the number of production recruiters varies. Lumping the two categories together provides the annual recurring costs of sustaining a production recruiter, which is believed to be a more useful figure.

Table F-3 of this appendix is a GRC-revised version of the original Service input displayed at Table F-1. The revisions were made to make the Services' estimates more comparable with one another. Explanatory footnotes have been provided for Table F-3 when significant adjustments were made to the original Service versions. The overall effect of these changes causes the Air Force costs to decline, Navy and Marine Corps costs to rise, and practically no change to the Army's total cost. Table F-4 summarizes the cost results by major categories.

Table F-4
ALTERNATIVE ANNUAL PRODUCTION RECRUITER COSTS

	Army	Navy	Marine Corps	Air Force	DOD average
Total costs					
Service estimate	\$29,700	\$25,100	\$27,400	\$52,600	\$35,400
GRC revised estimate	29,400	28,400	30,200	42,600	32,700
Annual recurring costs					
Service estimate	24,100	23,500	25,700	34,100	26,900
GRC revised estimate	25,500	25,200	27,200	32,300	27,500
FY75 recruiting budgets/number of production recruiters ^a	26,400 ^b	24,000	22,500	26,000	24,700

^aBased on POM data; rental costs assumed by Army (\$20.6 million) are allocated in proportion to the number of production recruiters authorized for each Service.

^bExcludes recruiter assistant costs; figure would rise to \$33,000 with those costs included.

A determination of what figures to use for analytical or comparison purposes will depend upon what the cost figures are used for. If the purpose is to develop a standard cost to use in adjusting the recruiting

budgets, the GRC-revised annual recurring cost estimates are probably the most appropriate. On the other hand, if the purpose is to determine cost to the overall DOD budget, the DOD average total cost estimate of \$35,000 is the most relevant.

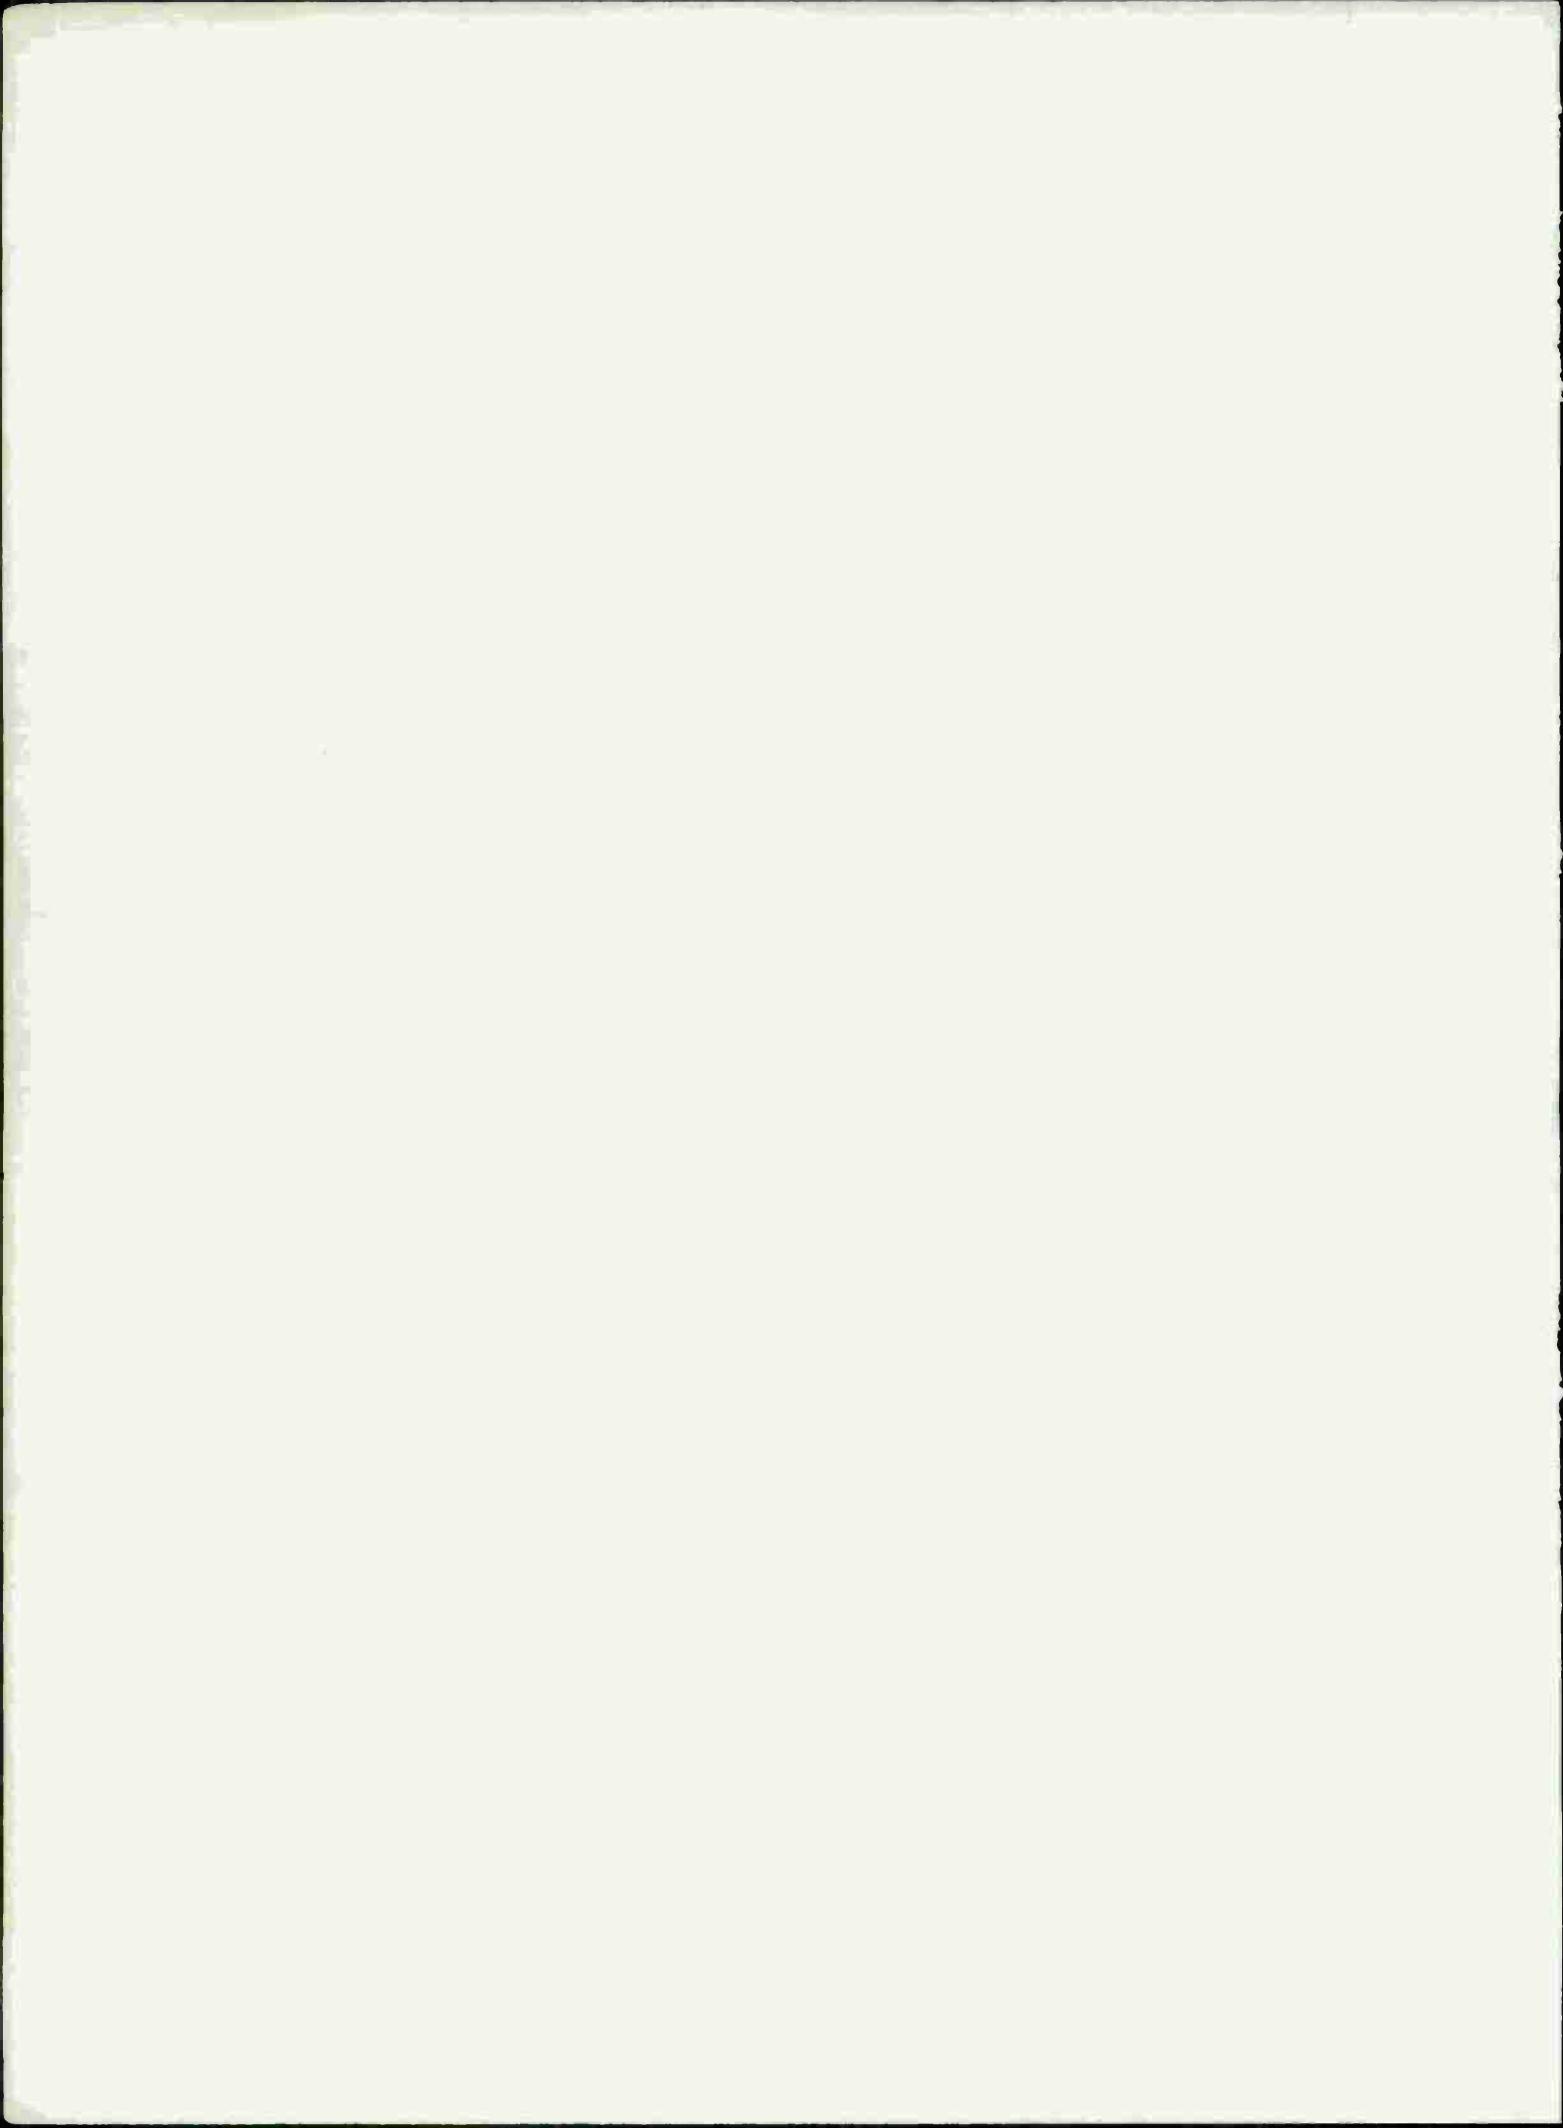

For determining the marginal annual cost of an additional recruiter, a good estimate could be obtained by taking the GRC annual recurring cost and adding the initial investment cost prorated over 2 years. For DOD-wide, this produces an average cost of \$30,100.

It is interesting to note that differing cost effectiveness results can be obtained using GRC's econometric measurements of the marginal recruiter productivity of male diploma high school graduates and the various annual recruiter cost estimates listed at Table F-4. Table F-5 summarizes those cost effectiveness results.

Table F-5
MARGINAL COST PER MALE DIPLOMA HIGH SCHOOL GRADUATE
USING ALTERNATIVE PRODUCTION RECRUITER COSTS

	Army	Navy	Marine Corps	Air Force
Annual marginal productivity for male high school graduates	4 ± 3	9 ± 2	2.5 ± 1	22 ± 5
Marginal costs				
Total cost				
Service estimate	7,425	2,790	10,960	2,390
GRC revised estimate	7,350	3,155	12,080	1,936
Annual recurring cost				
Service estimate	6,025	2,610	10,280	1,550
GRC revised estimate	6,375	2,800	10,880	1,468
FY75 budget/number or recruiters	6,600	3,333	9,000	1,181

The results show that, whatever recruiter cost estimate is chosen, the relative ranking among the Services in cost effectiveness does not change.
