An optimal estimation scheme is presented, which determines the satellite attitude using the gyro readings and the star tracker measurements of a commonly used satellite attitude measuring unit. The scheme is mainly based on the exponential Fourier densities that have the desirable closure property under conditioning. By updating a finite and fixed number of parameters, the conditional probability density, which is an exponential Fourier density, is recursively determined.

Simulation results indicate that the scheme is effective and robust. It is believed that this approach is applicable to many other attitude measuring units. As linearization and approximation are necessary in the approach, it is ideal for systems involving high levels of randomness.

When a system involves little randomness and linearization is not expected to incur much error, the approach can provide a benchmark against which such suboptimal estimators as the extended Kalman filter and the least-squares estimator can be compared. In this spirit, simulated data for HEAO-A were processed to compare the optimal scheme and the extended Kalman filter. The results are presented.

This work was supported by the Goddard Space Flight Center/NASA under Contract No. NAS5-24217 and the Air Force Office of Scientific Research, Air Force Systems Command, USAF, under Grant No. AFOSR-74-2671. NAS5-24217
1. Introduction

The project being reported on is mainly concerned with estimating the satellite attitude given the gyro readings and the star tracker measurements of a commonly used satellite attitude measuring unit (SAMU). The SAMU is used in such satellites as the high energy astronomy observatory (HEAO) and the precision pointing control system (PPCS) [1] [2]. It is composed of 3 to 6 rate gyros and 2 star trackers. The satellite attitude is propagated over a certain number of small time intervals by integrating the satellite angular rates determined from the gyro reading. Gyro drift rates, misalignments, and lack of a precise initial attitude reference then make it necessary to employ two gimbled star trackers to provide a benchmark to the further propagation of the satellite attitude. A star tracker utilizes an image dissector tube to locate the position of a star on its photosensitive surface. Due to the nonstationary nonlinear characteristics of the image dissector deflection coils and the white noise from the processing electronics, it is at this stage that estimation is required.

A new representation of a probability density of a three dimensional rotation called the exponential Fourier density (EFD), was recently introduced [3] [4], which has the desirable closure property under the operation of taking conditional distributions. Using the EFD's, an approach was suggested in [3] [4] to derive recursive formulas for updating the conditional densities of a rotational process given a nonlinear observation in additive white noise.

In this report, this approach is carried out for the aforementioned satellite attitude estimation problem. The recursive formulas for updating
the conditional densities of the satellite attitude are derived for arbitrary star tracker equations. These general formulas are included here to accommodate possible future consideration of the distortion characteristics of the image dissector deflection coils [1] [2] and possible future change in the star tracker configuration. These general formulas also provide a basis on which special cases can be easily analyzed. However, they involve a large amount of computation. Their feasibility for on-board implementation is highly questionable.

In a conversation with E. J. Lefferts of the GSFC/NASA, it was observed by him that by choosing appropriately the mathematical description of the star tracker configuration, the star tracker measurement can be expressed in closed form as a linear combination of the rotational harmonic functions of order one. This observation substantially simplifies the optimal estimation scheme and greatly reduces the amount of computation required in both designing and utilizing the scheme. A detailed derivation of the associated equations is included in the sequel. It is these equations that we use in implementation, simulation, and evaluation.

A total of 37 computer programs were created to carry out essentially the following tasks:

**TASK 1.** Simulating the satellite attitude propagation and measurement;

**TASK 2.** Updating the conditional density using the recursive formulas for its Fourier coefficients;

**TASK 3.** Integrating the conditional covariance matrix of the attitude quaternion;

**TASK 4.** Computing the maximum eigen-value and its eigenvector of the conditional covariance matrix and the estimation errors;
TASK 5. Searching for the maximum likelihood estimate.

TASK 6. Plotting the estimation errors.

A close look at the mathematical models (30) and (31) for the star tracker measurement, which are either used in [1] and [2] or modified by E. J. Lefferts of the GSFC/NASA, revealed that the measurement models are not observable.

The nonobservability causes a pseudo-image of each observed star. As the extended K-B filtering is merely a local processing, it does not pick up the pseudo-image and is therefore immune from its effect. In contrast, the optimal scheme does not have any "blind spots" and thus assigns an equal probability to the double images of each of the observed stars. An example illustrating such nonobservability is given in Section VI.

Fortunately enough, this difficulty resulting from the nonobservability can be remedied by introducing a "pseudo-measurement" of the second apparent star direction cosine $u_2(k)$ with respect to the tracker base reference axes. We note that $u_2(k)$ is the component of the direction vector $u(k)$ that is perpendicular to the tracker field-of-view and hence cannot be measured directly by the tracker. However, from using the satellite attitude estimate $\hat{s}(t)$ at the previous step $t=k-1$, $u_2(k)$ can be predicted, which is to be used as a "measurement" of the real $u_2(k)$. Facilitated with such a pseudo-measurement, the pseudo-image of the observed star can be eliminated. For want of a mathematically rigorous proof, only a heuristic explanation for this pseudo-measurement approach, which is believed to be new, is given in Section VII.

Among the six tasks mentioned above, TASK 3 is most CPU-time-consuming, which involves nine integrations on the 3-dimensional rotation group.
Encouraging is the fast and high concentration of the conditional probability
density at the satellite attitude under estimation. This phenomenon is
dictated by the theory and suggest two possible ways to get around the diffi-
culty of integration. One way is to localize the integration. Another way
is to use the maximum likelihood estimate instead of the optimal estimate.
Both methods were researched and implemented on the computer. The simulation
results indicate that there is virtually no difference between the estimates
obtained in these two ways (at least for the models used in the project).

The maximum likelihood estimator avoids not only integration altogether
but also TASK 4-computing the maximum eigenvalue and its eigenvector. All it
needs is the updated Fourier coefficients of the conditional density, which
are obtained through simple algebraic formulas. Therefore, the maximum like-
lihood estimator is used in comparison with the extended K-B filter, a stan-
dard method for spacecraft attitude estimation.

A comparison between the K-B filtering and our maximum likelihood esti-
mator was conducted by E. J. Lefferts of the GSFC/NASA. A. N. Mansfield of
the CSTA generated a sequence of 53 star tracker observations. The average
body rates were provided every one third of a second, and the tracker ob-
servation was taken every two minutes. The standard deviation of the tracker
measurement noises is 20 arcseconds. For such a low noise level, it is
known that linearization is a very good approximation. Therefore, it is
not surprising that the maximum likelihood estimator is not much better than
the K-B filter.

However, the comparison results indicate that the maximum likelihood
estimator is almost always better and converges faster than the K-B filter.
It is also noted that: (1) The simulated measurement data are in strict
accord with the system model, assuming all the true values of the model parameters and the noise statistics are given. (2) There is no random driving term in the state dynamics model for the spacecraft attitude. Under these two conditions in addition to the low measurement noise level mentioned above, even simple-minded estimators can be expected to perform near optimal. But these conditions are usually far from being met in reality. The simulated examples in Section IX, used to compare the ML and the optimal estimates, were chosen to test the robustness of our new schemes and represent tougher working conditions than the real ones. The simulation results to be depicted in graphs indicate that both the local integration estimator and the maximum likelihood estimator track the signal nicely. Unfortunately, we did not get to use the K-B filter for these cases. But, we believe that the extended K-B filter is no more valid especially for the third example.

The robustness of an estimator toward uncertainty of system parameters and the random driving term in the state dynamics is perhaps the most important consideration in real world application. While there is every reason to believe that the maximum likelihood estimator is superior in this regard, the issue remains to be resolved in hopefully our next project.

A description and a flow chart of each of the computer programs are given in the Appendix. A listing can be obtained from the data set called W9MN.TESTAL.FORT, which is stored in the IBM360/95 at the GSFC/NASA. The programs involved in each of the aforementioned tasks are listed as follows:
11. Propagation of the Satellite Attitude

The SAMU uses an inertial measuring unit (IMU) composed of 3 to 6 rate gyros, and two star trackers. Let the time $t$ be indexed by a discrete integration step $T$. A reading of the IMU is then taken, and compensations are applied by the computer to yield the estimated rate acting upon the satellite. This compensation is based upon the estimates of the gyro misalignments and drift rates. The compensated output, the three estimated angular velocities $[\omega_1, \omega_2, \omega_3]$ of the satellite, is then integrated to yield the estimated satellite attitude quaternion $\rho = [\xi, \eta, \zeta, \chi]^T$ as follows [1] [2]:

$$\rho_{k+1} = Q_k \rho_k$$

where

$$Q = \begin{bmatrix}
C_0 & \theta_3 S_0 & -\theta_2 S_0 & \theta_1 S_0 \\
-\theta_3 S_0 & C_0 & \theta_1 S_0 & \theta_2 S_0 \\
\theta_2 S_0 & -\theta_1 S_0 & C_0 & \theta_3 S_0 \\
-\theta_1 S_0 & -\theta_2 S_0 & -\theta_3 S_0 & C_0
\end{bmatrix}$$
\[ \theta_0 = T \left( \sum_{i=1}^{3} \omega_i^2 \right)^{1/2} \]

\[ S_0 = \sin \left( \frac{\theta_0}{2} \right) \]

\[ C_0 = \cos \left( \frac{\theta_0}{2} \right) \]

\[ \theta_i = \omega_i T, \ i = 1, 2, 3. \]

As the IMU parameters can be calibrated very accurately before the satellite is launched and the gyro noise level is extremely low, the estimation error of \((\omega_1, \omega_2, \omega_3)\) is assumed negligible to simplify the project. Hence if the initial attitude were known and if the IMU and computer performed ideally, then the attitude could be predicted precisely for all future time and no additional attitude measuring device would be required. Unfortunately this is not the case and two star trackers are utilized once every \(N\) time steps to acquire additional information about the satellite attitude.

As we are only concerned in this project with filtering the star tracker data to estimate the satellite attitude, the attitude propagation between two consecutive star tracker measurements can be obtained to yield the following state equation:

\[ p_{k+1} = Q_k p_k \]

(2)

where \(p_k = p_{kN}\) and \(Q_k = \prod_{j=0}^{N-1} Q_{kN+j}\)

We note that each time step in (2) is \(NT\).

Let \(p_k\) and \(Q_k\) be identified with their Euler angle representations \(s_k(\phi_k, \theta_k, \psi_k)\) and \(w_k(\alpha_k, \beta_k, \gamma_k)\) respectively. The equation (2) can thus be
rewritten in terms of Euler angles as

\[ s_{k+1}(\phi_{k+1}, \theta_{k+1}, \psi_{k+1}) = w_k(\alpha_k, \beta_k, \gamma_k) s_k(\phi_k, \theta_k, \psi_k) \]  

(3)

where \( \bullet \) denotes the product rotation and \((\alpha, \beta, \gamma)\) is related to the components \((Q)_{ij}\) of \(Q\) through

\[
\begin{align*}
\lambda &= \left[ (Q)_{11}^2 + (Q)_{21}^2 \right] \left[ (Q)_{41}^2 + (Q)_{31}^2 \right]^{\frac{1}{2}} \\
\sin\alpha &= -\frac{(Q)_{11}(Q)_{31} + (Q)_{21}(Q)_{41}}{\lambda} \\
\cos\alpha &= \frac{(Q)_{31}(Q)_{21} - (Q)_{11}(Q)_{41}}{\lambda} \\
\cos\beta &= 2\left((Q)_{11}^2 + (Q)_{21}^2\right) - 1, \quad 0 \leq \beta \leq \pi \\
\sin\gamma &= -\frac{(Q)_{21}(Q)_{41} - (Q)_{11}(Q)_{31}}{\lambda} \\
\cos\gamma &= -\frac{(Q)_{11}(Q)_{41} + (Q)_{31}(Q)_{21}}{\lambda}
\end{align*}
\]  

(4)

Hence the time sequence \([\alpha_k, \beta_k, \gamma_k]\) can be easily determined from the satellite angular velocity \([\omega_1, \omega_2, \omega_3]\) through (1) - (4). This sequence will be used in the optimal estimation equations to be derived in the sequel.

III. General Recursive Formulas for Conditional Densities

The star tracker measurements (to be denoted by \(m_k\)) are nonlinear functions of the satellite attitude \(s_k\) corrupted in additive white noise (to be denoted by \(v_k\)). A general mathematical model can be written as

\[ m_k = h(s_k, k) + v_k \]  

(5)

where \(m_k\), \(h(s_k, k)\), and \(v_k\) are all r-vectors. The measurement noise \(v_k\) is caused by the processing electronics of the star trackers and it is customari-
ly assumed Gaussian. We write its density function as

\[ p(v_k) = (2\pi)^{-\frac{r}{2}}(\text{det} R_k)^{-\frac{1}{2}}\exp\left\{-\frac{1}{2} \sum_{i,j=1}^{r} R_{ik} v_i v_k\right\} \] (6)

where \( R_{ij} \) is the \( ij \)-th component of the covariance matrix \( R_k \) of \( v_k = [v_{k1}, \ldots v_{kr}]^T \).

As suggested in [3] and [4], the function \( h(\cdot, k) \) for each \( k \) must be approximated very closely by a finite Fourier series. By a slight abuse of the symbol \( h \), it will also be used to denote its Fourier approximate, i.e.

\[ h(s_k, k) = \sum_{\ell=0}^{\ell} \sum_{m=-\ell}^{\ell} h_{\ell mn}^{(k)} D_{\ell mn}^{(k)}(s_k) \] (7)

where the rotational harmonic function \( D_{\ell mn} \) is defined, in terms of the Euler angles \( (\phi, \theta, \psi) \), by

\[ D_{\ell mn}^{(\phi, \theta, \psi)} = \frac{1}{i^{m-n}} \exp[-i(m\phi+n\psi)] d_{\ell mn}^{(\phi)} \quad , \quad i = (-1)^{\frac{1}{2}} \] (8)

\[ d_{\ell mn}^{(\phi)} = \sum_{t} (-1)^{t} \frac{[(\ell+m)!(\ell-m)!](\ell+n)!(\ell-n)!]}{(\ell+m-t)!(t+n-m)!t!(\ell-n-t)!} \frac{1}{2} \]

\[ \cdot \cos^2 t \cdot \sin^2 \theta \cdot \frac{1}{2} \]

As \( h \) is a real function, the above Fourier series can be written in the alternative form, called the real form as contrasted to the complex form (7),

\[ h(s_k, k) = \frac{1}{2^\ell} h_{00}^{\ell} (k) D_{00}^{\ell} (s_k) + \sum_{m,n=-\ell}^{\ell} \left[ h_{1mn}^{\ell} (k) \Re D_{mn}^{\ell} (s_k) + h_{2mn}^{\ell} (k) \Im D_{mn}^{\ell} (s_k) \right] \] (10)

or \( m=n>0 \)
where the real coefficients $h_{1mn}$ and $h_{2mn}$ are related with the complex coefficient $h_{mn}^\ell$ through

$$h_{mn}^\ell = \frac{1}{2} \left( h_{1mn}^\ell - i h_{2mn}^\ell \right)$$  \hspace{1cm} (11)

The $i$-th components of $h$ and $h_{mn}^\ell$ will be denoted by $h_i$ and $h_{mn}^\ell_i$ respectively.

A set of Fortran IV programs to compute $h_{mn}^\ell$'s and the approximation error was written and successfully tested on the IBM360/95 at the GSFC/NASA. Descriptions and flow charts of the programs are given in the Appendix.

It is assumed that the conditional density of $s_{k-1}$ given $m^{k-1} = \{m_1, \ldots, m_{k-1}\}$ is an exponential Fourier density of order $2L$, i.e.

$$p(s_{k-1}|m^{k-1}) = \exp \sum_{\ell=0}^{2L} \sum_{m, n = -\ell} p_{mn}^{\ell, k-1} p_{\pi n}(s_{k-1})$$  \hspace{1cm} (12)

for $k$ equal to a positive integer. We note that a rotational normal density is an exponential Fourier density of order 1. The reason for choosing the order $2L$ will become clear in the following derivation of the recursive formulas for $p_{mn}^\ell$.

By Bayes' rule, we have

$$p(s_{k}|m^k) = c_k p(m_k|s_k) p(s_{k}|m^{k-1})$$  \hspace{1cm} (13)

where $c_k$ is a normalizing constant.

As $w_k$ is a group element, from (3) it follows that $s_{k-1} = w_k^{-1} \circ s_k$.

Substituting this into (12) yields
\[ p(s_k|m^{-1}) = \exp \sum_{p_{mn}} p_{\ell,k-1} \frac{\ell}{m} (w_{k-1} \circ s_k) \]
\[ = \exp \sum_{p_{mn}} p_{\ell,k-1} \sum_{q=-1}^{\ell} D_{mq} (w_{k-1}) D_{qn} (s_k) \]
\[ = \exp \left( \sum_{q=-\ell}^{\ell} p_{\ell,k-1} \sum_{q=-\ell}^{\ell} D_{qm} (w_{k-1}) D_{mn} (s_k) \right) \] (14)

where \( \sum_{\ell=0}^{2l} \sum_{m,m'=-\ell} \) and the second equality holds because \( h_{mn}^\ell \) is a matrix representation of the three dimensional rotation group.

From (5), (6), and the definition of the conditional density, it is clear that

\[ p(m_k | s_k) = (2\pi)^{-\frac{r}{2}} \left( \det R_k \right)^{-\frac{1}{2}} \exp \left[ \frac{1}{2} \sum_{i,j=1}^{r} R_{ij} (m_i - h_i (s_k, k)) (m_j - h_j (s_k, k)) \right] \]
\[ = C_k \exp \left[ \frac{1}{2} \sum_{i,k=1}^{r} R_{ij}^\ell (m_i - \sum_{\ell=0}^{L} \sum_{m,n=-\ell} h_{mn}^\ell (s_k)) (m_j - \sum_{\ell'=0}^{L} \sum_{m'n'=\ell'} h_{m'n'}^\ell (s_k)) \right] \]
\[ = C_k \exp \left[ C_0 + \sum_{\ell=0}^{L} \sum_{m,n=-\ell} C_{mn}^\ell (s_k) + \sum_{\ell,\ell'=0}^{L} \sum_{m,n=-\ell} \sum_{m'n'=-\ell'} C^{\ell'}_{mn} (s_k) D_{mn}^\ell (s_k) \right] \] (15)

where

\[ C_0 = \frac{1}{2} \sum_{i,j=1}^{r} R_{ij}^\ell m_i^j m_k^j \]
\[ C_{mn}^\ell = \frac{1}{2} \sum_{i,j=1}^{r} R_{ij}^\ell (m_i^j h_{mn}^\ell (k) + m_k^j h_{mn}^\ell (k)) = \sum_{i,j=1}^{r} R_{ij}^\ell h_{mn}^\ell (k) \] (16)
Furthermore, it is known [5, p.160] that

\[
\psi_{mn}^{(s_k)}(s_k) = \sum_{q=q_0}^{\ell+\ell'} (2q+1)(-1)^{m''-n''} \begin{pmatrix} \ell & \ell' & q \\ m & m' & -m'' \end{pmatrix} \begin{pmatrix} \ell & \ell' & q \\ n & n' & -n'' \end{pmatrix} u_{m''n''}^{q}(s_k)
\]

(18)

\[m'' = m + m',\]
\[n'' = n + n',\]
\[q_0 = \max(\{\ell-\ell', |m'|, |n''|\})\]

\[
\binom{j k \ell}{m n p} = (-1)^{2j-k+n} \frac{(j+k-l)!(k+j-l)!(j+l-k)!(l+p)!(l-p)!}{(j+k+1)!(j+m)!(j-m)!(k+n)!(k-n)!}
\]

\[
\sum_{t} (-1)^{t} \frac{(l+j-n-t)!(k+n+t)!}{(l+p-t)!(t+k-j-p)!t!(l-k+j-t)!}
\]

(19)

where the sum on \(t\) is over values such that the arguments of all the factorial functions are nonnegative. Let us define the symbols:

\[
\gamma q \left( \begin{array}{c} \ell \ m \ n \\ \ell' m' n' \end{array} \right) = C_{\ell' m'}^{\ell m} (2q+1)(-1)^{m''-n''} \begin{pmatrix} \ell & \ell' & q \\ m & m' & -m'' \end{pmatrix} \begin{pmatrix} \ell & \ell' & q \\ n & n' & -n'' \end{pmatrix}
\]

(20)

\[
r q (\ell, \ell', m''n'') = \sum_{m''-\ell k \leq m}^{m''-\ell k \leq m} \gamma q \left( \begin{array}{c} \ell \ m \ n \\ \ell' m'' n''-n \end{array} \right)
\]

(21)
Using essentially (18), the last term in (15) is transformed into a linear combination of the rotational harmonics as follows:

\[
\sum_{\ell, \ell' = 0}^{L} \sum_{m, n, m', n'} C^{\ell \ell'}(m, n, m', n') D^{\ell'}_{mn}(s_k) D^{\ell'}_{m'n'}(s_k)
\]

Substituting (22), (15), and (14) into (13), we obtain

\[
p(s_k | m^k) = \exp \left[ \sum_{\ell = 0}^{2L} \sum_{m, n = -\ell}^{\ell} \left( \sum_{q = \ell - \ell'}^{\ell + \ell'} \frac{1}{q!} \sum_{m, n = -q}^{q} r^{q}(\ell, \ell', m', n') \right) b^{q}_{mn}(s_k) \right]
\]

the constants \( c_k, c'_k, \) and \( C_0 \) being absorbed into the coefficient of \( D^{00}_0(s_k) = 1 \),
which is a normalizing constant, and \( \chi_{[0,L]} \) is the characteristic function for 
\([0,L]\).

We note that \( p(s_k^m) \) is also an exponential Fourier density of order \( 2L \). Comparing (12) and (24), we obtain the recursive formula for \( p_n^{L_k} \):

\[
\begin{align*}
p_{mn}^{L_k} &= \sum_{q=-L}^{L} p_{qn}^{L_k} \chi_{[0,L]}(w_{k-1}^{-1}) + \Gamma_{mn}^{L_k} + \chi_{[0,L]}(L_k)C_{mn}^{L_k} \\
\end{align*}
\]

where \( \Gamma \) and \( C \) are defined by (20)-(22) and (16).

The function enclosed in the brackets in (24) is a real function. It is often easier to express it in the real form of the Fourier series. Using the notational convention established in (10) and (11), the equation (24) can be written as

\[
\begin{align*}
p(s_k^m) &= \exp \left[ \frac{2L}{L=0} \left( \frac{1}{2} P_{100}^{L_k} p_{00}^{L_k}(s_k) + \sum_{m,n=-L}^{L} \left( \begin{array}{c} p_{1mn} \text{Re} \Delta_{mn}^{L_k}(s_k) \\
\end{array} \right) \right) + \frac{2L}{L=0} \left( \begin{array}{c} p_{2mn} \text{Im} \Delta_{mn}^{L_k}(s_k) \\
\end{array} \right) \right) \\
\end{align*}
\]

\( \frac{2L}{\frac{1}{2} P_{100} = \text{the normalizing constant} \)

The recursive formulas for \( p_{1mn}^{L_k} \) and \( p_{2mn}^{L_k} \) can be deduced from (25) as follows:

\[
\sum_{q=-L}^{L} p_{qn}^{L_k} \Delta_{qn}^{L_k}(w_{k-1}^{-1}) = \sum_{q=-L}^{L} \frac{1}{2} \left( p_{1qn}^{L_k} - i p_{2qn}^{L_k} \right) \left( \frac{\text{Re} \Delta_{mn}^{L_k}(w_{k-1}^{-1}) + \text{Im} \Delta_{mn}^{L_k}(w_{k-1}^{-1})} \right)
\]
\[ c^\ell_{mn} = \frac{1}{2} \sum_{i,j=1}^r \left( R^i_{k_m} h^j_{1mn} - i R^i_{k_m} h^j_{2mn} \right) \]

\[ c^\ell_{mn} = \sum_{q,q'=0}^L \sum_{|q-q'| \leq \ell < q+q'}^{q-q'| \leq q+q'} \sum_{-q-t,s<q'}^{m-q-t<q+q'} q^\ell(q,q',m,n) = \sum_{q,q'=0}^L \sum_{|q-q'| \leq \ell < q+q'}^{q-q'| \leq q+q'} \gamma^\ell(q,m-t,n-s) \]

\[ \gamma^\ell(q,m-t,n-s) = (-1)^{m-n}(2\ell+1)\left( q,q',\ell \right)\left( q,q',\ell \right) c^{qq'}(t,s,m-t,n-s) \]

\[ c^{qq'}(t,s,m-t,n-s) = \frac{1}{8} \sum_{i,j=1}^r \left[ \begin{array}{c} h^{q'i} h^{q'j} \\ h^{q'i} h^{q'j} \end{array} \right] \left( t,s,1,1,m-t,n-s \right) - \frac{1}{2} \left( h^{q'i} h^{q'j} \right) \left( t,s,2,2,m-t,n-s \right) \]

\[ \ell^k_{1mn} = 2R \ell^k_{mn}, \quad \ell^k_{2mn} = -2i \ell^k_{mn} \]

\[ \ell^k_{1mn} = \sum_{q=-\ell}^\ell \left( p^1_{qmn} R^q_{k} q_{m}^q q_{k}^{-1} + p^2_{qmn} \Im D^q_{q_{m}} q_{k}^{-1} \right) \]

\[ \ell^k_{1mn} + X_{0,L}(\ell) \sum_{i,j=1}^r R^i_{k_m} h^j_{1mn} + \sum_{q,q'=0}^L \sum_{|q-q'| \leq \ell < q+q'}^{m-q-t<q+q'} \sum_{n=n-q}^{n+q'} (-1)^{m-n+1} \frac{2\ell+1}{4} \]

\[ \sum_{q-t,s<q'}^{m-q-t<q+q'} \]
\[
\begin{pmatrix}
q & q' & \ell \\
t & m-t & -m \\
q & q' & \ell \\
s & n-s & -n
\end{pmatrix}
\begin{pmatrix}
R_{k}^{ij} \begin{bmatrix}
q_i & q_j \\
m-t & n-s \\
q_i & q_j \\
m-t & n-s
\end{bmatrix}
\begin{bmatrix}
h_{\ell t} s, t, n-s \\
h_{\ell t} s, t, n-s
\end{bmatrix}
\end{pmatrix}
\begin{pmatrix}
2t s, 2, m-t, n-s \\
2t s, 2, m-t, n-s
\end{pmatrix}
\]

(27)

\[\ell_{k} = \sum_{q=-\ell}^{\ell} \chi_{0, L}^{(\ell)} (q) \sum_{i,j=1}^{r} R_{i}^{j} h_{2mn}^{m} \left( p_{2q}^{l} (w_{k-1}^{l-1}) - p_{1q}^{m} (w_{k-1}^{m-1}) \right) \]

(28)

IV. Star Tracker Equations in Terms of Harmonics

A star tracker is a telescope-detector system mounted with two degrees of freedom to the satellite. The field of view of the detector is an 8 by 8 degree window whose center point is on the optical axis and whose plane is normal to this axis. A star appearing within this window is sensed by the detector and, after some electronic processing, results in the output of two voltages representing the position of the star within the window along two mutually perpendicular axes.

When a star tracker observation is taken at time \( k \), the star is identified from a star map and its apparent direction cosines \( a(k) = [a_1(k), a_2(k), a_3(k)]^T \) with respect to the earth-centered inertial set of coordinate system can be easily computed from the absolute velocity of the satellite. The apparent star direction cosines \( u(k) = [u_1(k), u_2(k), u_3(k)]^T \) with respect to the tracker base reference axes are related to \( a \) as follows:
\[ u(k) = A_{x}^{T} A_{x}^{x} A_{x}^{z}(k)a(k) \]  

(29)

where \( A_{x} \) is the constant 3 x 3 orthogonal matrix representing the orientation of the tracker base reference axes with respect to the satellite base reference axes and \( A_{x}^{z}(k) \) is the 3 x 3 orthogonal matrix representing the satellite attitude with respect to the earth-centered inertial set at time \( k \).

The mathematical model used [1] and [2] for the relationship between the tracker output voltages \([y_1(k), y_3(k)]\) and \( u(k) \) is the following:

\[
\begin{bmatrix}
  y_1(k) \\
  y_3(k)
\end{bmatrix} = 
\begin{bmatrix}
  -u_1(k)/u_2(k) \\
  u_3(k)/u_2(k)
\end{bmatrix} 
+ 
\begin{bmatrix}
  n_1(k) \\
  n_3(k)
\end{bmatrix}
\]  

(30)

With \([n_1(k), n_3(k)]\) denoting two independent white Gaussian noise, the model is only an approximation. It was pointed out by E. J. Lefferts of the GSFC/NASA that the following model provides just as good an approximation to the relationship between \([y_1(k), y_3(k)]\) and \( u(k) \):

\[
\begin{bmatrix}
  y_1(k) \\
  y_3(k)
\end{bmatrix} = 
\begin{bmatrix}
  -u_1(k) \\
  u_3(k)
\end{bmatrix} 
+ 
\begin{bmatrix}
  n_1(k) \\
  n_3(k)
\end{bmatrix}
\]  

(31)

It will be seen later that the components of \( A_{x}^{z} \) are simple linear combinations of the rotational hermonics of order 1. Whence so are the components of \( u(k) \). Using the model (31), we do not need to use the set of Fortran IV programs provided in the Appendix to compute \( h_{mn}^{(f)}(k) \)'s in (7) to approximate \( h(s_k, k) \). Above all, the star observed by the star tracker changes from time
to time and thus \( h(s_k, k) \) is a time-varying function. Using the Fortran programs to compute \( h_{mn}(k) \)'s for each star observation may amount to unbearable computational burden, especially when the estimation has to be done on board the satellite. The use of the model (31) not only eliminates such a difficulty but also keeps minimal the number of harmonics required to update the conditional densities of the satellite attitude. In the following, we will restrict our attention to the model (31).

The SAMU uses two star trackers. We will use a single underline and a double underline to refer to Star Tracker I and Star Tracker II, respectively, e.g., \((u_1, u_2, u_3)\) denotes the apparent star direction cosines in the Star Tracker II base reference axes \((x_1^2, x_2^2, x_3^2)\). When the underlines are omitted, the equations are valid for both star trackers.

We pool the measurements from the two star trackers and write

\[
\begin{bmatrix}
1 \\
2 \\
3 \\
4 \\
\end{bmatrix}
\begin{bmatrix}
m_k^1 \\
m_k^2 \\
m_k^3 \\
m_k^4 \\
\end{bmatrix}
= m_k = h(s_k, k) + v_k =
\begin{bmatrix}
h^1(s_k, k) \\
h^2(s_k, k) \\
h^3(s_k, k) \\
h^4(s_k, k) \\
\end{bmatrix}
+ \begin{bmatrix}
v_k^1 \\
v_k^2 \\
v_k^3 \\
v_k^4 \\
\end{bmatrix}
\]  

where

\[
\begin{bmatrix}
h^1(s_k, k) \\
h^2(s_k, k) \\
h^3(s_k, k) \\
h^4(s_k, k) \\
\end{bmatrix}
= \begin{bmatrix}
-u_1(s_k, k) \\
u_3(s_k, k) \\
-u_3(s_k, k) \\
u_3(s_k, k) \\
\end{bmatrix}
\]  

(33)
We will now express $u_j$ as a linear combination of the rotational harmonics of order 1: We recall that

$$d_{mn}^l(0) = \sum_{t=\max(0,m-n)}^{\min(l-n,l+m)} (-1)^t \frac{[(l+m)!(l-m)!(l+n)!(l-n)!]^2}{(l+m-t)!(t+n-m)!t!(l-n-t)!} \cdot \cos^{2l+m-2t} \frac{\theta}{2} \sin^{2t+n-m} \frac{\theta}{2}$$

(34)

$$d_{mn}^l(\phi,\theta,\psi) = \exp \left[ \left( \frac{m}{2} - \phi \right) m - \left( \frac{n}{2} + \psi \right) n \right] d_{mn}^l(0)$$

(35)

whence

$$
\begin{bmatrix}
\text{Im}D_{11} & \text{Re}D_{01} & \text{Re}D_{11} \\
\text{Im}D_{-10} & D_{00} & \text{Re}D_{01} \\
\text{Im}D_{-11} & \text{Im}D_{01} & \text{Re}D_{11}
\end{bmatrix}
= 
\begin{bmatrix}
\frac{1}{2} \sin(\phi+\psi)(1+\cos\theta) & \frac{1}{2} \sin\phi \sin\theta & \frac{1}{2} \cos(\phi+\psi)(1-\cos\theta) \\
\frac{1}{2} \cos\phi \sin\theta & \cos\theta & -\frac{1}{2} \sin\phi \sin\theta \\
\frac{1}{2} \sin(\phi-\psi)(1-\cos\theta) & \frac{1}{2} \cos\phi \sin\theta & \frac{1}{2} \cos(\phi-\psi)(1+\cos\theta)
\end{bmatrix}
$$

The matrix $A_{xz}$ can then be expressed in terms of the harmonics as follows:

$$
A_{xz} = 
\begin{bmatrix}
\cos\phi \cos\psi - \sin\phi \cos\theta \sin\psi & \cos\phi \sin\psi + \sin\phi \cos\theta \cos\psi & \sin\phi \sin\theta \\
-\sin\phi \cos\psi - \cos\phi \sin\theta \sin\psi & -\sin\phi \sin\psi + \cos\phi \cos\psi \cos\theta & \cos\phi \sin\theta \\
\sin\phi \sin\theta & -\cos\phi \sin\theta & \cos\theta
\end{bmatrix}
$$

$$
A_{xz} = 
\begin{bmatrix}
\text{Re}D_{11} - \text{Re}D_{-11} & -\text{Im}D_{-11} - \text{Im}D_{11} & -\sqrt{2} \text{Re}D_{01} \\
-\text{Im}D_{-11} + \text{Im}D_{11} & \text{Re}D_{11} + \text{Re}D_{-11} & -\sqrt{2} \text{Im}D_{01} \\
\sqrt{2} \text{Re}D_{01} & \sqrt{2} \text{Im}D_{-10} & D_{00}^1
\end{bmatrix}
$$

(36)
Let the ixj-th component of the constant matrix $A$ be denoted by $m_{ij}^x$.

From (29), it follows that, for $j = 1, 2, 3$ and for both star trackers,

$$u_j(k) = m_ja_3(k)D_0^1(s_k) + \sqrt{2}m_ja_1(k)ReD_{-10}^1(s_k) + (m_ja_2(k) - m_{j1}a_1(k))ReD_{-11}^1(s_k)$$

$$- \sqrt{2}m_ja_3(k)ReD_{01}^1(s_k) + (m_ja_1(k) + m_ja_2(k))ReD_{11}^1(s_k)$$

$$+ \left[ \sqrt{2}m_ja_2(k)ImD_{-1}^1(s_k) - (m_ja_2(k) + m_ja_1(k))ImD_{-11}^1(s_k) \right]$$

$$- \sqrt{2}m_ja_3(k)ImD_{01}^1(s_k) + (m_ja_1(k) - m_ja_2(k))ImD_{11}^1(s_k)$$

(37)

The Fourier coefficients, $h_{1mn}^i(k)$'s and $h_{2mn}^i(k)$'s for $h^i(s_k, k)$ can be easily identified from (33) and (37) and will not be displayed here. We only note that they can be very easily determined from the star direction $a(k)$ and the recursive formulas are then readily applicable.

V. Updating the Conditional Densities Using Star Tracker Measurements

We shall now display the recursive formulas for the conditional densities of the satellite to be used in the next two modules of this project. The star tracker equations are (32), (33), and (37) developed in the previous section. We assume that the measurement noise process $v_k$ has statistically independent components, i.e., $R_{ij}^k = 0$, if $i \neq j$.

We recall that the function $h^i$ in (33) is a linear combination of the first order harmonics, $ReD_{1mn}^1$ and $ImD_{1mn}^1$. Hence $h_{1mn}^q = h_{2mn}^q = 0$ unless $q = 1$. This observation greatly simplifies the multiple summation sign in
front of the brackets in (27) and (28):

\[
\sum_{q,q'\leq 0} = \sum_{|q-q'| \leq q+q'} = \sum_{\max(-1,m-1)\leq t\leq \min(1,m+1)} \sum_{\max(-1,n-1)\leq s\leq \min(1,n+1)}
\]

In view of the assumption that \(R_{i,j}^k = 0\), for \(i\neq j\), we obtain from (27) and (28) the following recursive formulas: for \(\ell = 1, 2\) and \(m, n = -\ell, \ldots, \ell, \ell\)

\[
P_{1mn}^{\ell} = \sum_{q=-\ell}^{\ell} p_{1qn}^{\ell,k-1} \text{Re} D_{q}^{\ell} (w_{k-1}^{-1}) + p_{2qn}^{\ell,k-1} \text{Im} D_{q}^{\ell} (w_{k-1}^{-1})
\]

\[
+ \chi_{[0,L]}(\ell) \left[ \sum_{j=1}^{4} R_{jj} \sum_{s=1}^{m-1} h_{s}^{l,j} \sum_{s=1}^{n-1} h_{s}^{l,j} \right] \left[ \sum_{s=1}^{\min(1,n+1)} \right]
\]

\[
P_{2mn}^{\ell} = \sum_{q=-\ell}^{\ell} \left( p_{2qn}^{\ell,k-1} \text{Re} D_{q}^{\ell} (w_{k-1}^{-1}) - p_{1qn}^{\ell,k-1} \text{Im} D_{q}^{\ell} (w_{k-1}^{-1}) \right)
\]

\[
+ \chi_{[0,L]}(\ell) \left[ \sum_{j=1}^{4} R_{jj} \sum_{s=1}^{m-1} h_{s}^{l,j} \sum_{s=1}^{n-1} h_{s}^{l,j} \right] \left[ \sum_{s=1}^{\min(1,n+1)} \right]
\]

\[
+ h_{l,t,s}^{l,j} h_{2,t,s}^{l,j} \]
where, from (19),

\[
\begin{pmatrix}
1 & 1 & \ell \\
t & m-t & -m
\end{pmatrix}
= (-1)^{1+m-t} \left[ \frac{\ell!(\ell-m)!}{(\ell+\ell)!} \frac{1+m-t}{(1+t)!} \frac{1-m+t}{(1-m+t)!} \right]^{1/2}
\]

\[
\min(\ell-m, \ell) \sum_{r=\max(0, -m)}^{\ell} (-1)^r \frac{(\ell+1-m+t-r)!}{(\ell-m-r)!} \frac{(1+m-t+r)!}{(r+m)!} \frac{1}{(\ell-r)!}
\]

(40)

The conditional density \( p(s_k/m) \) is then obtained through (26):

\[
p(s_k/m) = \exp \left[ \sum_{\ell=0}^{2} \frac{1}{2^\ell 100^\ell} \sum_{m,n=-\ell}^{\ell} p_{1mn} \Re D_{mn}(s_k) + p_{2mn} \Im D_{mn}(s_k) \right]
\]

(26)

\[
\frac{1}{2} p_{100} = \text{the normalizing constant}
\]

It is noted that there are 35 Fourier coefficients, \( p_{1mn} \) and \( p_{2mn} \), which are recursively computed by reasonably simple scalar equations (38) and (39).

II. Nonobservability of the Star Tracker Equations

We consider the mathematical model (31), to be repeated in the following, for the star tracker measurement in this section. Our argument here applies also to the model (30). We recall that the model (31) is

\[
\begin{align*}
\begin{bmatrix}
y_1(k) \\
y_3(k)
\end{bmatrix}
&= \begin{bmatrix}
-u_1(s_k, k) \\
u_3(s_k, k)
\end{bmatrix}
+ \begin{bmatrix}
n_1(k) \\
n_3(k)
\end{bmatrix}
\end{align*}
\]

(31)

\[
u(s_k, k) = A_{xx} A_{xz}(k)a(k)
\]

(29)

where \( a(k) \) is the apparent direction cosines of the observed star with respect
to the earth-centered inertial set $\mathbf{1}$ of coordinate system, $A^x()$ is the constant 3x3 orthogonal matrix representing the orientation of the tracker base reference axes $x^t$ with respect to the satellite base reference axes $x$, and $A_x(k)$ is the 3x3 orthogonal matrix representing the satellite attitude with respect to the earth-centered inertial set at time $k$.

The SAMU uses two star trackers. We will use a single underline and a double underline to refer to Star Tracker I and Star Tracker II, respectively. When the underlines are omitted, the equations are valid for both star trackers.

We pool the measurements from the two star trackers and write, suppressing the time variable $k$,

$$
\begin{bmatrix}
  m_1 \\
  m_2 \\
  m_3 \\
  m_4
\end{bmatrix} = m = h(s) + v = \\
\begin{bmatrix}
  h^1(s) \\
  h^2(s) \\
  h^3(s) \\
  h^4(s)
\end{bmatrix} + \\
\begin{bmatrix}
  v^1 \\
  v^2 \\
  v^3 \\
  v^4
\end{bmatrix}
$$

where

$$
\begin{bmatrix}
  h^1(s) \\
  h^2(s) \\
  h^3(s) \\
  h^4(s)
\end{bmatrix} = \\
\begin{bmatrix}
  -u_1(s) \\
  u_3(s) \\
  -u_1(s) \\
  u_3(s)
\end{bmatrix}
$$

We say that the measurements $m$ are not observable, meaning that there are two different states, $s$ and $f$, that the measurements $m$ can not distinguish, i.e., $h(s) = h(f)$. This nonobservability is essentially caused by the lack of information about $u_3(s)$ in the model (31).
The vector \( u(s) \) is the apparent direction cosines of the observed star with respect to the tracker base reference axes and its second component \( u_2(s) \) is either positive or negative \( \sqrt{1 - u_1^2(s) - u_3^2(s)} \). Furthermore, the star tracker looks in the positive direction of \( u_2(s) \). Hence, 

\[
u_2(s) = \sqrt{1 - u_1^2(s) - u_3^2(s)} \quad \text{and} \quad u_2(s)
\]

and \( u_3(s) \), which are directly measured in (31). Indeed, the physical system that (32) and (33) try to describe is observable. But the direction of the star tracker is by no means taken into consideration in the model (31) (nor in (30)). We will now illustrate this point with the following example.

Example. Assume that

\[
A_{x^0} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad a = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}
\]

\[
A_{x^1} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix}, \quad a = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}
\]

\[
s = A_{x^1} a = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}
\]

\[
f = A_{x^1} f = \begin{bmatrix} 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix}
\]
Simple calculations yield

\[
\begin{align*}
    u(s) &= A_s \begin{bmatrix} x_t & s & a \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \end{bmatrix} \\
    u(s) &= A_s \begin{bmatrix} x_t & s & a \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \\
    u(f) &= A_f \begin{bmatrix} x_t & f & a \end{bmatrix} = \begin{bmatrix} 0 \\ -1 \\ 0 \end{bmatrix} \\
    u(f) &= A_f \begin{bmatrix} x_t & f & a \end{bmatrix} = \begin{bmatrix} 0 \\ -1 \\ 0 \end{bmatrix}
\end{align*}
\]

Hence,

\[
\begin{align*}
    h(s) &= \begin{bmatrix} -u(s) \\ u_3(s) \\ -u_1(s) \\ u_2(s) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} -u_1(f) \\ u_3(f) \\ -u_1(f) \\ y_3(f) \end{bmatrix} = h(f)
\end{align*}
\]

We note that this example is also valid for the model (30) for which

\[
h(s) = [-u_1(s)/u_2(s), u_3(s)/u_2(s), -u_1(s)/u_2(s), u_3(s)/u_2(s)]^T.
\]

As the star trackers look in the positive \( u_2 \) direction, the direction cosines \( u(f) \), of which the second component is negative, cannot be those of the observed star. They only form a pseudo-image of the observed star,
which the measurements (32) and (33) can not distinguish from the real image of the same star.

VII. Remedying the Nonobservability

We recall that the conditional density \( p(m_k | s_k) \) is used in calculating \( p(s_k | m^k) \) and that

\[
p(m_k | s_k) = (2\pi)^{-r/2} (\det R_k)^{-1/2} \exp \left\{ \frac{1}{2} \sum_{i,j=1}^{r} R_k^{-1} (m_k - h(s_k))(m_k - h^j(s_k)) \right\}
\]

where \( r \) is the dimension of the measurement vector \( m \). From this equation, it is clear that \( p(m_k | s_k) \) takes on the same value at the state \( s \) and at the pseudo-state \( f \) resulting respectively from the images \( u(s) \) and the pseudo-images \( u(f) \) of the observed stars, since \( h(f) = h(s) \).

In order to eliminate such effect of the star pseudo-images, a new approach, which we call the pseudo-measurement technique, was developed. The idea is pretty simple. Supposing that \( u_2 \) and \( u_2 \) were directly measured and (32) and (33) became

\[
\begin{bmatrix}
  m_1 \\
  m_2 \\
  m_3 \\
  m_4 \\
  m_5 \\
  m_6
\end{bmatrix}
= m = h(s) + v =
\begin{bmatrix}
  h_1(s) \\
  h_2(s) \\
  h_3(s) \\
  h_4(s) \\
  h_5(s) \\
  h_6(s)
\end{bmatrix}
+ \begin{bmatrix}
  v_1 \\
  v_2 \\
  v_3 \\
  v_4 \\
  v_5 \\
  v_6
\end{bmatrix}
\]

(41)
and
\[
\begin{bmatrix}
    h^1(s) \\
    h^2(s) \\
    h^3(s) \\
    h^4(s) \\
    h^5(s) \\
    h^6(s)
\end{bmatrix}
= \begin{bmatrix}
    -u_1(s) \\
    u_3(s) \\
    -u_1(s) \\
    u_3(s) \\
    u_2(s) \\
    u_2(s)
\end{bmatrix}
\]  

(42)

the equation (15) would remain unchanged with \( r = 6 \) instead of 4. Of course, \( m_k^5 \) and \( m_k^6 \) are not really available. However, if the estimate \( \hat{s}_{k-1} \) of \( s_{k-1} \) is good, then \( u_2(w_{k-1} \hat{s}_{k-1}) \) and \( u_2(w_{k-1} \hat{s}_{k-1}) \) should be equally good estimates of \( m_k^5 \) and \( m_k^6 \). It seems only natural to use \( u_2(w_{k-1} \hat{s}_{k-1}) \) and \( u_2(w_{k-1} \hat{s}_{k-1}) \) as measurements of \( u_2(s_k) \) and \( u_2(s_k) \), respectively.

Now setting

\[
\begin{align*}
    v^5 &= u_2(w_{k-1} \hat{s}_{k-1}) - u_2(s_k) \\
    v^6 &= u_2(w_{k-1} \hat{s}_{k-1}) - u_2(s_k) \\
    m^5 &= u_2(w_{k-1} \hat{s}_{k-1}) \\
    m^6 &= u_2(w_{k-1} \hat{s}_{k-1})
\end{align*}
\]  

(43)

we retrieve exactly (42) and (43). Here, the question is whether we still have (15) with \( r = 6 \). This obviously depends on the conditional sampling distributions of \( v^5 \) and \( v^6 \) in (44) given the state \( s_k \) at time \( k \) which unfortunately remains unclear as of today. We note only that \( \hat{s}_{k-1} \) is a measurable function of \( m_{k-1} = \{m_1, \ldots, m_{k-1}\} \) and hence \( v^i(k) \) and \( v^6(k) \) are conditionally independent of \( v^i(k), i=1, \ldots, 4 \).

We recall that the nonobservability problem arises from the missing sign of \( u_2 \). Perhaps we do not need all that much information about \( u_2 \) as might be possible to obtain from a precise expression of the conditional
sampling distributions of $v^5$ and $v^6$, as long as the effect of the pseudo-images of the observed stars can be eliminated without affecting (15) with $r=4$. This can indeed be achieved by assuming that the conditional sampling distributions of $v^5$ and $v^6$ are normal. First of all, the equation (15) is valid again with $r=6$ under this assumption. Secondly, by setting $R^5$ and $R^6$ equal to 4, we assign a probability of 95% to a positive value of $u_2$, leaving the equation (15) with $r=4$ relatively intact. Thirdly, in view of the central limit theorem, the assumption may not be hard to swallow after all.

VIII An Estimation Error Criterion and the Optimal Estimate

In order to define an error criterion for orientation estimation, it is necessary to have a measure of the distance between two orientations. We will first describe such a measure, using quaternions. We recall that a rotation about an axis in the direction of a unit vector $[\ell, m, n]^T$ through an angle $\phi$ is represented by the (unit) quaternion

$$q = [q_1, q_2, q_3, q_4]^T = [\ell \sin \frac{\phi}{2}, m \sin \frac{\phi}{2}, n \sin \frac{\phi}{2}, \cos \frac{\phi}{2}]^T$$

Given two orientations, the minimal angle in radians required to bring one into the other is a natural measure of distance between them and defines a Riemannian metric on $SO(3)$. If the orientations are represented by the quaternions, $q$ and $p$, and the minimal angle is denoted by $\rho(q, p)$, then we have $q^T p = \cos \frac{1}{2} \rho(q, p)$. As $\frac{1}{2} (1 - \cos \rho)$ is a monotone increasing function of $\rho$, a measure of distance between $p$ and $q$ can be defined to be $\frac{1}{2} (1 - \cos \rho(q, p)) = 1 - (q^T p)^2$. It can be shown that if the orientations, $q$ and
p, are described by the 3x3-dimensional orthogonal matrices, Q and P, then
this measure of distance can also be expressed as $\frac{1}{4} (3 - \text{tr} \, PQ^T)$.

We are now ready to define the error criterion for orientation estimation.
Let $q$ be a random quaternion and $p$ its estimate. Then a measure of the esti-
mation error is

$$J(q, p) = E(1 - (q^T p)^2)$$  \hspace{1cm} (44)

If the probability distribution of $q$ is given, the estimate $p$ which
minimizes $J$ may be obtained from observing that $J(q, p) = 1 - p^T E(qq^T)p$.
It is well-known that the quadratic form $p^T V p$ of the positive definite
matrix $V = E(qq^T)$ is maximized when $p$ is the unit eigenvector associated
with the largest eigenvalue $\lambda$ of $V$. Moreover, the maximum value is $\lambda$.
Hence,

$$\min_p J(q, p) = 1 - \hat{q}^T E(qq^T) \hat{q} = 1 - \lambda$$

where

$\lambda$ = the maximum eigenvalue of $E(qq^T)$

$\hat{q}$ = the unit eigenvector of $E(qq^T)$

associated with $\lambda$.

The probability distributions on SO(3) are expressed in terms of the
Euler angles $(\phi, \theta, \psi)$ in (26). The following relationships between the
quaternion components and the Euler angles will have to be used to calcu-
late the optimal estimate $\hat{q}$ and its estimation error $1 - \lambda$:

$$q_1 = \sin \frac{\theta}{2} \cos \frac{\phi - \psi}{2}$$
$$q_2 = \sin \frac{\theta}{2} \sin \frac{\phi - \psi}{2}$$
$$q_3 = \cos \frac{\theta}{2} \sin \frac{\phi + \psi}{2}$$
$$q_4 = \cos \frac{\theta}{2} \cos \frac{\phi + \psi}{2}$$
IX. Simulation Results

Three simulated examples with various system parameters and noise levels are given in this section. They were chosen to test the robustness of the optimal scheme and therefore represent tougher working conditions than the real ones. The measurement noise, \( v_i \) in (42), is set at two different levels to illustrate how the noise level can affect the estimator performance. The variance, \( 1/R_{ii} \), of \( v_i \) is 1/36 for A part of the examples, and is \( 10^{-4} \) for B part of the examples. The reader is referred to the Module II report for the specification of all the system parameters.

The four graphs of the A part of the \( i^{th} \) example are, respectively,

**GRAPH (i, A, 1):**

the error, \( ERH_1 \), of the optimal estimate obtained by local integration

---

the error, \( ERH_2 \), of the maximum likelihood estimate

**GRAPH (i, A, 2):**

The same as GRAPH (i, A, 1) except that the vertical scale is changed and the points at \( k = 1 \) and 2 are removed to magnify the vertical variations.

**GRAPH (i, A, 3):**

---

the distance between the maximum likelihood estimate and the optimal estimate obtained by local integration

**GRAPH (i, A, 4):**

The same as GRAPH (i, A, 3) except that the vertical scale is changed and the points at \( k = 1 \) and 2 are removed to magnify the vertical variations.
The symbols to be used to specify the system parameters and noise levels are defined as follows:

1. The attitude propagation equation is

\[ s_{k+1}(\phi_{k+1}, \theta_{k+1}, \psi_{k+1}) = w_k(\phi_k, \theta_k, \psi_k) \cdot s_k(\phi_k, \theta_k, \psi_k) \]  \hspace{1cm} (3)

2. The initial attitude at \( k=0 \) is represented by a quaternion \( s_0 = [q_1, q_2, q_3, q_4]^T \).

3. The initial distribution of \( s_0 \) has a rotational normal density

\[ p(s_0) = c \exp \left[ a \left( \sum_{i=1}^{4} b_i q_i \right)^2 \right] \]

4. The Euler angles \( \alpha_k, \beta_k, \gamma_k \) are obtained from multiplying the constants \( c_1, c_2, c_3 \), resp., by pseudo-random numbers from the uniform distribution on the interval \([0, 1]\).

5. The star tracker measurement and the pseudo-measurement equations are

\[ m_k^i = h_k^i(s_k^i, k) + v_k^i, \quad i=1, \ldots, 6 \]  \hspace{1cm} (42)

where

\[ P(v) = (2\pi)^{-3} \left( \sum_{i=1}^{6} R_i v_i \right)^6 \exp \left( -\frac{1}{2} \sum_{i=1}^{6} R_{ii}(v_i)^2 \right) \]

6. The apparent direction cosines \( u \) with respect to a star tracker and those \( a \) with respect to the earth are related by

\[ u(k) = A_{x1}^T A_{x2}^T A_{x3}^T\mbox{}^i_{k}(k) a(k) \]  \hspace{1cm} (29)
EXAMPLE 1.

1 & 0 & 0 \\
0 & 0 & 1 \\
0 & -1 & 0 \\
\end{bmatrix}
\]
Remark. Let us recall the nonobservability example given in Section II. The pseudo-state of the real state $s_0$ is exactly $[b_1, b_2, b_3, b_4]$, which is chosen to be the mode of the initial density of $s_0$. The pseudo-measurement technique thus picks wrongly the pseudo-state at the first time-point. This example was in fact deliberately designed to work against the pseudo-measurement technique. The simulation results to be depicted in the following graphs indicate without doubt that the pseudo-measurement technique has unbelievable self-correcting power and switches to the real images of the stars very quickly (at the second time-point in this example).

PART A

GRAPH (3, A, 1)

GRAPH (3, A, 2)

GRAPH (3, A, 3)

GRAPH (3, A, 4)
Comparison Between the Maximum Likelihood Estimates and the K-B Estimates

We note again that it takes much more CPU time to compute the optimal estimates even by local integration and, based on the simulation results, the local integration estimates are not much better than the maximum likelihood estimates. Therefore, a comparison was made between the K-B estimation and the maximum likelihood estimation instead of the optimal estimation.

The comparison was conducted by E. J. Lefferts of the GSFC/NASA. A. N. Mansfield of the CSTA generated sequences of 33 star tracker observations. The average body angular velocity was provided every one third of a second, and the tracker observation was taken every two minutes. The standard deviation of the tracker measurement noises is 20 arcseconds.
For such a low noise level, it is known that linearization is a very good approximation and the extended K-B filter is expected to be near optimal. Indeed, our comparison results confirmed these long-standing conjectures. Two typical examples were included in the following. We note that the maximum likelihood estimates are almost always better and converge faster than the K-B estimates. However they are close, especially in the steady states.

The system parameters and the noise statistics for the two comparison runs to be reported in the following will now be given, using the symbols established in Section IV of the Module II report:

\[
\begin{align*}
A_{t} &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix} \\
X_{t} &= \begin{bmatrix} 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}
\end{align*}
\]

The four graphs of the \( i \)-th example are, respectively,

GRAPH \((i, 1)\):

- - - - - - - - - - - - - - - - - - -
the angular error in arcseconds of the K-B estimate

GRAPH \((i, 2)\):

The same as GRAPH \((i, 1)\) except that the vertical scale is changed and the points at \( k=1, \ldots, 4 \) are removed to magnify the vertical variations.
GRAPH (i, 3):
the angular error of the K-B estimate minus that of the
maximum likelihood estimate

GRAPH (i, 4):
The same as GRAPH (i, 3) except that the vertical scale is changed and
the points at k=1, ..., 4 are removed to magnify the vertical variations.

ACKNOWLEDGMENTS

The author would like to acknowledge with thanks Mr. Eugene J.
Lefferts of GSFC/NASA for many valuable discussions and suggestions and
Dr. Arthur Mansfield of CSTA for generating measurement data. Special
thanks go to Dr. Masahiro Nishihama for his excellent programming job.
This work would not have been possible without their contributions.

Input:

PA12 2π
N number of subintervals in [0, 2π]
NZ number of subintervals in [0, 2π] for the first and third Euler angles $\phi, \psi$
MT number of subintervals in [0, π] for the second Euler angle $\theta$
H0 mesh for integration ($= 2\pi/N$)
H mesh for integration ($= 2\pi/NZ$)
D mesh for integration ($= \pi/MT$)
AXX 2x3x3 dimensional array representing each orientation of the star tracker base reference axes with respect to the satellite base reference axes.

AD 2x3 - dimensional array representing the apparent direction cosines of a star observed by each of the two star trackers with respect to the earth-centered inertial set of coordinate system.

WØ satellite attitude propagation, Euler angles, 3-dim. array.

QN quaternion form of WØ, 4-dim. array.

PØ, QØ coefficients of harmonics in \( P(s_k|m^k) \), which will be updated for \( P(s_k|m^k) \) to \( \tilde{P}_1, Q_1 \), 2x5x5-dim. arrays.

AK parameter of the rotational normal distribution of the initial satellite attitude \( S_0 \).

AA, BB coefficients of \( \{\text{Re}D^{1}_{\text{lin}}(s_k)\} \), \( \{\text{Im}D^{1}_{\text{lin}}(s_k)\} \) in 6-dim. function \( h(s_k,K) \), 6x3x3-dim. arrays.

RR diagonal elements of the covariance matrix for the normal distribution of the observation noise, 6-dim. array.

SINE, COSN table of \( \sin \phi, \cos \phi \), 33-dim. arrays.

SDD1, SDD2 \( \{d^1_{\text{lin}}(\theta)\}, \{d^2_{\text{lin}}(\theta)\} \) for \( \text{Re}D^\ell_{\text{lin}}(\phi,\theta,\psi) \), \( \text{Im}D^\ell_{\text{lin}}(\phi,\theta,\psi) \) for \( \ell = 1,2 \), 3x3x17 and 5x5x17-dim. arrays.

QS attitude \( s_{k-1} \), 4-dim. array.

QHØ \( (k-1) \)th stage maximum likelihood estimate of \( s_{k-1} \) to generate a predicted estimate of \( s_k \), 4-dim. array.

IXØ, IYØ initial random integers which create measurement noise, satellite attitude propagation, and AD.

Output

OBN star tracker measurements, 6-dim. array.

P1,Q1 updated coefficients of the harmonics in the conditional density \( P(s_k|m^k) \), 2x5x5-dim. arrays, input for the \( (k+1) \)th stage.
QS1 attitude $s_k$, 4-dim. array, renamed as QS.

QSP predicted estimate of $s_k$, generated by $W\theta$ and $QH\theta$, 4-dim. array.

SH1 estimate $\hat{s}_k$ of the satellite attitude $s_k$, 4-dim. array.

QH1 sequence of $\{\hat{s}_k\}$, 4x50-dim. array.

SH2 maximum likelihood estimate $\hat{s}_k$ of $s_k$.

QH2 sequence of $\{\hat{s}_k\}$, 4x50-dim. array.

ER1 estimation error of the attitude estimate $\hat{s}_k$.

ERRN sequence of estimation errors, 50-dim. array.

ER2 distance between $s_k$ and $\hat{s}_k$, $\rho(s_k, \hat{s}_k)$.

ERH1 sequence of $\{\rho(s_k, \hat{s}_i)\}$, 50-dim. array.

ER3 distance between $s_k$ and $\hat{s}_k$, $\rho(s_k, \hat{s}_k)$.

ERH2 sequence of $\{\rho(s_k, \hat{s}_k)\}$, 50-dim. array.

ER4 distance between $\hat{s}_k$ and $\hat{s}_k'$, $\rho(\hat{s}_k, \hat{s}_k')$.

ER12 sequence of $\{\rho(\hat{s}_k, \hat{s}_k')\}$, 50-dim. array.

Special Considerations:

1. Parameter AD is generated at each stage $k$ from $s_k$ considering the deviation from the value $a$ in the equation.

$$\begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} = A_{xx} \cdot A_{x2}(s_k) u$$

this is done in 'ADC'.

2. Attitude propagation $W\theta$ is generated at each stage in 'NEW\theta'.
3. Measurement OBN consists of six components, which are

\[ \text{OBN}(i) = \text{FU}(i, DD, AA, BB) + V(i) \quad 1 \leq i \leq 4 \]
\[ \text{OBN}(i) = \text{FU}(i, DD, AA, BB) \quad 5 \leq i \leq 6 \]

For \( 1 \leq i \leq 4 \), DD represents \( \{ \text{ReD}^{1}_{\frac{m}{n}}(s_{k}) \}, \{ \text{ImD}^{1}_{\frac{m}{n}}(s_{k}) \} \)

For \( 5 \leq i \leq 6 \), DD represents \( \{ \text{ReD}^{1}_{\frac{m}{n}}(\hat{s}_{k}) \}, \{ \text{ImD}^{1}_{\frac{m}{n}}(\hat{s}_{k}) \} \)

where \( \hat{s}_{k} = w_{k-1} \hat{s}_{k-1} \), called predicted estimate of \( s_{k} \).

In this sense, OBN is called pseudomeasurements.

4. The initial distribution \( p(s_0) \) is assumed to be a rotational normal distribution on \( SO(3) \) with parameter \( A_{K} \).

5. In order to reduce integration time, 32 subintervals for \( \phi, \psi \) and 16 subintervals for \( \theta \) are used in the trapezoidal rule, where \( 0 \leq \phi, \psi \leq 2\pi \), \( 0 \leq \theta \leq \pi \).

6. In the computation of optimal estimate \( \hat{s}_{k} \) and estimation error, tables of \( \sin\phi, \cos\phi, d_{\frac{m}{n}}^{1}(\theta), d_{\frac{m}{n}}^{2}(\theta) \) are used instead of calling subprograms.

7. Integer \( KK \) indicates which stage should be updated and \( MM \) shows at \( (MM-1) \) stages, the values \( QSN, QH1, QH2, ERRN, ERH1, ERH2, ERI2 \). Skipping given steps JMP.

8. At the end of each stage, necessary data are stored in the disk space and will be read at the beginning of RUN by TRANS.

STOP
ADC

A Subprogram

Purpose:

To choose two appropriate sets of apparent direction cosines AD with respect to the earth-centered inertial coordinate system.

Calling Sequence:

CALL  ADC(AXX, DD, V1, V2, AD)

Common Variables:

None

Input:

AXX 2x3x3-dim. array representing the orientation of the two sets of the start tracker base reference axes with respect to the satellite base reference axes, given in the main program, \( A_{tx} \).

DD 3x3-dim. array representing \( D_{mn}^{1}(s_k) \), computed by 'DRI2'.

V1, V2 4-dim. arrays representing random numbers from the normal distribution.

Output:

AD 2x3-dim. array representing apparent direction cosines, \( a(k) \).

Special Considerations:

1. First AD(=a) is chosen to satisfy the relation

\[
\begin{bmatrix}
0 \\
1 \\
0
\end{bmatrix} = A_{tx} \cdot A_{xz} \cdot a
\]

then \( a \) is replaced by \( a + v \) and normalized. In the program, the orthogonality of \( A_{tx}, A_{xz} \) is used.
2. $v$ is of normal distribution with a relatively small variance for the realistic simulations.

3. If $\|a + v\| = 0$, then $v_i$ is replaced by $v_i/2$ to avoid $\|a + v\| = 0$.

Other Subprograms Called:

None.
Flow Chart

\[
A_{xz} = \begin{bmatrix}
\text{Re}D_{11}^{1} - \text{Re}D_{-11}^{1} & -\text{Im}D_{-11}^{1} - \text{Im}D_{11}^{1} & -\sqrt{2}\text{Re}D_{01}^{1} \\
-\text{Im}D_{-11}^{1} + \text{Im}D_{11}^{1} & \text{Re}D_{11}^{1} + \text{Re}D_{-11}^{1} & -\sqrt{2}\text{Im}D_{01}^{1} \\
\sqrt{2}\text{Re}D_{-11}^{1} + \sqrt{2}\text{Im}D_{-10}^{1} & \sqrt{2}\text{Im}D_{-10}^{1} & \text{D}_{00}^{1}
\end{bmatrix}
\]

\[

T(2) = A(2) + H · (NT/2)
W(1) = A(3) - H · (NW/2)
W(2) = A(3) + H · (NW/2)

RETURN
A Subprogram

Purpose:
To set up tables of the coefficients of the following six functions expressed as harmonic series on SO(3),

\[ [u, u_3, u_1 u_3, u_2, u_3]^T \]

where \( u_j(k) \) is the \( j^{th} \) direction cosine of a star tracker at time \( k \) and is given by

\[
\begin{align*}
u_j(k) &= m \cdot a(k) \cdot D_{10}^1(s_k) + \frac{\sqrt{2}}{2} m_3 a_1(k) \cdot ReD_{10}^1(s_k) \\
&+ (m_2 a_2(k) - m_1 a_1(k)) \cdot ReD_{21}^1(s_k) - \frac{\sqrt{2}}{2} m_1 a_3(k) \cdot ReD_{01}^1(s_k) \\
&+ (m_1 a_1(k) + m_2 a_2(k)) \cdot ReD_{11}^1(s_k) \\
&+ [\sqrt{2} m_3 a_2(k) \cdot ImD_{10}^1(s_k) - (m_1 a_2(k) + m_2 a_1(k)) \cdot ImD_{10}^1(s_k) \\
&- \frac{\sqrt{2}}{2} m_2 a_3(k) \cdot ImD_{01}^1(s_k) + (m_2 a_1(k) - m_1 a_2(k)) \cdot ImD_{01}^1(s_k) ]
\end{align*}
\]

Calling Sequence:

CALL COEFF1(AXX, AD, AA, BB)

Common Variables:
None

Input:

AXX Two sets of star tracker base reference axes with respect to the satellite base reference axes, given in the main program, 2x3x3 dimensional array, AXX(1,i,j) for the first start tracker and AXX(2,i,j) for the second, \( m \) in the equation of \( u_j(k) \).
AD 2x3 dimensional array representing the apparent direction cosines with respect to the earth-centered inertial set of coordinate system, given in the main program, $a_i(k)$ in the equation $u_j(k)$.

Output:

AA 6x3x3 dimensional array representing the coefficients of $\text{Re} D_{mn}^1(s_k)$ in $-u_1$, $u_3$, $-u_1$, $u_3$, $u_2$ and $u_2$.

BB 6x3x3 dimensional array representing the coefficients of $\text{Im} D_{mn}^1(s_k)$ in the six functions.

Special Considerations:

1. The coefficients are arranged and stored in AA and BB. For example, the coefficients of $-u_1$ are stored in AA (1, 2, 3) as follows

$$AA(1,2,3) = \begin{bmatrix} -(m_3^1a_1 + m_2^1a_2) - \sqrt{2}m_2^3a_1 - (m_3^2a_2 - m_2^1a_1) \\ -\sqrt{2}m_3^1a_3 - 2m_3^3a_3 - \sqrt{2}m_2^3a_1 \\ -(m_3^2a_2 - m_2^1a_1) - \sqrt{2}m_3^1a_3 - (m_3^1a_1 + m_3^2a_2) \end{bmatrix}$$

where the coefficients of $\text{Re} D_{mn}^1(s_k)$ are placed in A(1, 2, 3).

The arrangement of coefficients are made, so that one can express $u_j(k)$ as an expansion of $(\text{Re} D_{mn}^1(s_k))$ and $(\text{Im} D_{mn}^1(s_k))$ for $-1 < m, n < 1$, not only under the condition on $m, n$: $m < n$ or $m = n$ and $m > 0$, which is given in the original equation $u_j(k)$. Considering the fact $\text{Re} D_{mn}^1(s_k) = (-1)^{n-m} \text{Re} D_{-m-n}^1(s_k)$ and $\text{Im} D_{mn}^1(s_k) = (-1)^{n-m+1} \text{Im} D_{-m-n}^1(s_k)$, we use the following matrix form to see the sign difference between the elements $(m+2, n+2)$ and $(-m+2, -n+2)$.

$$\begin{bmatrix} 1 & 1 & 1 \\ -1 & 1 & 1 \\ 1 & -1 & 1 \end{bmatrix}$$ for the real part and

$$\begin{bmatrix} -1 & 1 & 1 \\ 1 & 0 & 1 \\ -1 & 1 & 1 \end{bmatrix}$$ for the imaginary part.

BB(1,2,2) = 0.0

\[\text{Return}\]
A Subprogram

Purpose:

To compute \( \binom{J_1}{J_2 J_3} \binom{M N P}{J_1 J_2 J_3} \)

\[
= (-1)^{J_1-J_2+N} \frac{(J_1+J_2-J_3)!}{(J_3+J_1-J_2)! (J_3+P)! (J_3-P)!} (J_1-J_2+J_3+1)! (J_1+m)! (J_1-M)! (J_2+N)! (J_2-N)!
\]

\[
\times (-1)^t \frac{(J_3+J_1-N-t)!}{(J_3+P-t)! (t+J_2-J_1-P)! t!(J_3-J_2+J_1-t)!}
\]

where

\[ M_L \leq t \leq M_U \]

\[ M_L = \max(0, J_1+P-J_2, -J_2-N) \]

\[ M_U = \min(J_3+J_1-N, J_3+P, J_3-J_2+J_1) \]

Calling Sequence:

\[ Y = C3J(J_1, J_2, J_3, M, N, P) \]

Input:

\[ J_1, J_2, J_3 \quad \text{non-negative integer with a condition} \]

\[ \max(J_1-J_2, J_2-J_1) \leq J_3 \leq J_1+J_2 \]

\[ M, N, P \quad \text{integers with conditions} \]

\[ -J_1 \leq M \leq J_1 \]

\[ -J_2 \leq N \leq J_2 \]

\[ -J_3 \leq P \leq J_3 \]

Common Variables:

None.
Special Considerations:

1. If $M_J < M_L$, then $Y = 0.0$

2. In order to avoid the case

   $(-1)^* = 0$, (for example $(-1)^*KJ$),

   $KJ$ is replaced by $KJ + a$ large even integer.

N

C3J = 0.0

M1 = M1

\[ C = \sum (-1)^t \frac{(J3+J1-N-t)!(J2+N+t)!}{(J3+P-t)!(t+J2-J1-P)!(J3-J2+J1-t)!} \]

\[ C3J = (-1)^2J-K+N \left( AA \frac{1}{BB} \right)^2 \cdot C \]

Return
A Subprogram

Purpose:

To determine a box region around the mode of the conditional density function \( P(\phi, \theta, \psi) = C \cdot \exp(f(\phi, \theta, \psi)) \) for local integrations.

Calling Sequence:

```
CALL DMN0 (P, Q, A, FMAX, Z, T, W)
```

Common Variables:

- \( P \) 2
- \( Q \) (\( P_{\text{lmn}} \), \( P_{\text{klm}} \), 2x5x5-dim arrays, respectively
- \( A \) Mode \( (\phi_0, \theta_0, \psi_0) \) of the function \( f(\phi, \theta, \psi) \) obtained in 'MAXI', 3-dim array
- \( FMAX \) Maximum \( f(s) \) on SO(3)

Output:

- \( Z \) First Euler angles \( \phi_1, \phi_2 \), 2-dim array
- \( T \) Second Euler angles \( \theta_1, \theta_2 \), 2-dim array
- \( W \) Third Euler angles \( \psi_1, \psi_2 \), 2-dim array

\( (Z(i), T(i), W(k)) \) 1 \( \leq i, j, k \leq 2 \) represents coordinates of a corner of the resulting box region

Special Consideration:

1. \( Z(1) < A(2), T(1) < T(2), W(1) < W(2) \)
2. \( \phi_1 \) is determined by decreasing \( \phi \) in \( f(\phi, \theta_0, \psi_0) \) until it reaches a constant \( C_0 \). On the other hand \( \phi_2 \) is determined by increasing \( \phi \) in \( f(\phi, \theta_0, \psi_0) \). The other Euler angles \( \theta_1, \theta_2, \psi_1, \psi_2 \) are obtained similarly.
3. The constant $C_0$ is computed by

\[
C_0 = \begin{cases} 
\text{Max } f(\phi, 0, \psi) & -175.0 \text{ if } \text{Max } f \geq 0 \\
-10.0 & \text{if } \text{Max } f < 0
\end{cases}
\]

RETURN
A Subprogram

Purpose:
To calculate $\text{Re}D_{mn}(s)$ and $\text{Im}D_{mn}(s)$ at $s=(q_1,q_2,q_3,q_4)$ and store the results in the matrix DD. The following relations are used.

\[
\begin{align*}
q_1^2 &= \frac{1}{4} - \frac{D_{00}}{4} + \frac{\text{Re}D_{11}}{2} \\
q_2^2 &= \frac{1}{4} - \frac{D_{00}}{4} - \frac{\text{Re}D_{11}}{2} \\
q_3^2 &= \frac{1}{4} + \frac{D_{00}}{4} - \frac{\text{Re}D_{11}}{2} \\
q_4^2 &= \frac{1}{4} + \frac{D_{00}}{4} + \frac{\text{Re}D_{11}}{2} \\
q_1q_2 &= -\frac{\text{Im}D_{11}}{2} \\
q_1q_3 &= \frac{\sqrt{2}}{4} (\text{Re}D_{11} - \text{Re}D_{01}) \\
q_2q_4 &= \frac{\sqrt{2}}{4} (\text{Re}D_{11} + \text{Re}D_{01}) \\
q_3q_4 &= -\frac{\text{Im}D_{11}}{2} \\
q_1q_4 &= -\frac{\sqrt{2}}{4} (\text{Im}D_{10} + \text{Im}D_{01}) \\
q_2q_3 &= -\frac{\sqrt{2}}{4} (\text{Im}D_{01} - \text{Im}D_{10}) \\
\end{align*}
\]

Calling Sequence:

\text{CALL DRI2(Q, DD)}

Common Variables:
None.

Input:
\begin{itemize}
\item Q \quad 4\text{-dimensional array representing a quaternion.}
\end{itemize}
Output:

\[ \text{DD} \] 3-dimensional array for \( \text{Re}_{\mu
\nu}(s) \), \( \text{Im}_{\mu
\nu}(s) \)

Special Considerations:

1. The values \( \text{Re}_{\mu
\nu}(s) \), \( \text{Im}_{\mu
\nu}(s) \) are stored in the following way

\[
\text{DD}(\cdot,\cdot) =
\begin{bmatrix}
\text{Im}_{\mu
\nu}^{11} & \text{Re}_{\mu
\nu}^{10} & \text{Re}_{\mu
\nu}^{11} \\
\text{Im}_{\mu
\nu}^{10} & \text{Re}_{\mu
\nu}^{00} & \text{Re}_{\mu
\nu}^{01} \\
\text{Im}_{\mu
\nu}^{11} & \text{Im}_{\mu
\nu}^{01} & \text{Re}_{\mu
\nu}^{11}
\end{bmatrix}
\]

\[
= \begin{bmatrix}
-2q_{1}q_{4} & \sqrt{2}(q_{1}q_{3}+q_{2}q_{4}) & q_{2}^{2} - q_{1}^{2} \\
\sqrt{2}(q_{2}q_{3}-q_{1}q_{4}) & 1-2(q_{1}^{2} + q_{2}^{2}) & \sqrt{2}(q_{2}q_{4}-q_{1}q_{3}) \\
-2q_{1}q_{2} & -\sqrt{2}(q_{1}q_{4}+q_{2}q_{3}) & q_{4}^{2} - q_{3}^{2}
\end{bmatrix}
\]

Other Subprograms Called:

\[ D(1, 3) = q_2^2 - q_1^2 \]

\[ D(2, 1) = \sqrt{2} (q_2 q_3 - q_1 q_4) \]
\[ D(2, 2) = 1 - 2 (q_1^2 + q_2^2) \]
\[ D(2, 3) = \sqrt{2} (q_2 q_4 - q_1 q_3) \]

\[ D(3, 1) = -2 q_1 q_2 \]
\[ D(3, 2) = -\sqrt{2} (q_1 q_4 + q_2 q_3) \]
\[ D(3, 3) = q_4^2 - q_3^2 / 3 \]

Return
EIGEN

A Subprogram

Purpose:
To compute eigenvalues and eigenvectors of a given real symmetric matrix by tridiagonalization.

Calling Sequence:

CALL EIGEN(N, A, E, V)

Common Variables:

None.

Input:

N    dimension of matrix a (≤ 4)
A    2-dim. array containing the symmetric matrix.

Output:

E    array containing the computed eigenvalues in absolute descending order.
V    eigenvectors stored in columns.

Special Considerations:

None.

Other Subprograms Called:

TRIDMX, EIGVAL, EIGVEC.
Flow Chart

BEGIN

Tridiagonalization of A
(TRIDMX)

Eigenvalues E
(EIGVAL)

Eigenvectors V
(EIGVEC)

Return
EIGVAL

A subroutine

Purpose:

To compute the eigenvalues of a symmetric tridiagonal matrix using Sturm sequences.

Calling Sequence:

CALL EIGVAL(LP, E, A, B, W, F)

Common Variables

None.

Input:

LP
A
B

order of tridiagonal matrix
LP-dim. array containing the diagonal elements of the tridiagonal matrix.
LP-dim. array containing off-diagonal elements in B(2) through B(N). B(1) = 0.0.

Output:

E
W
F

LP-dim. array containing the computed eigenvalues in absolute descending order.
LP-dim. dummy array.
LP-dim. dummy array.

Special Considerations:

1. The diagonal matrix is not fed into the subroutine as a matrix. Instead, the main diagonal is stored in the A array. The off-diagonal elements are stored in B(2) through B(N). B(1) must be equal to zero.
2. EIGVAL is designed to be used after calling TRIDMX. The output from TRIDMX is in the correct form for input to EIGVAL.

Other Subprograms Called:

EIGVEC
A subprogram

Purpose:
To compute the eigenvectors of a real symmetric tridiagonal
matrix using Wilkinson's method.

Calling Sequence:
CALL EIGVEC(LP, NM, R, A, B, E, V, P, Q)

Input:
LP  order of tridiagonal matrix.
NM  maximum number of rows that the tridiagonal matrix
can have as specified by the DIMENSION statement
     in the calling program.
R   NMXNM-dim. array containing the transformation vectors
     used to reduce the symmetric matrix to tridiagonal
     form.
A   N-dim. array containing the diagonal elements of the
     tridiagonal matrix.
B   N-dim. array containing the off-diagonal matrix in B(2)
     through B(N).
E   N-dim. array containing the eigenvalues of the tridiagonal
     matrix.

Output:
V   NMXNM-dim. array containing the eigenvectors stored in
     columns of the tridiagonal matrix.
P   N-dim. dummy array for temporary storage.
Q   N-dim. dummy array for temporary storage.
Special Considerations:

1. EIGVEC is designed to be called after TRIDMX and EIGVAL. The transformation vectors needed in A are computed by TRIDMX. The tridiagonal matrix itself is not fed into the subroutine as a matrix. Rather, the diagonal elements are in the D array and the off-diagonal elements are in the B array. TRIDMX will put those respective elements in those arrays.

2. The accuracy of the eigenvectors is determined by the separation of the eigenvalues. The closer the eigenvalues, the less accurate the eigenvectors. In case of multiple eigenvalues, multiple eigenvectors will be computed.

Other Subprograms Called.

ERR

A Subprogram

Purpose:

1. To determine the maximum value of a function in the exponent of the conditional density function \( p(s_k|m^k) \) and Euler angles where the function is maximum.

2. To compute the normalizing constant for \( p(s_k|m^k) \).

3. To evaluate \( E(q\cdot q^T) \) with respect to \( p(s_k|m^k) \) and to find the maximum eigenvalue \( \lambda \) of \( E(q\cdot q^T) \) and its eigenvector \( p \) so that

\[
\text{ERR1} = 1 - \lambda = 1 - \frac{1}{p}E(q\cdot q^T)p
\]

is the optimal estimation error.

4. To find distances between \( s_k \) and \( \hat{s}_k \), between \( s_k \) and \( \hat{s}_k \), and between \( \hat{s}_k \) and \( \hat{s}_k \) on \( S^2(3) \), where \( \hat{s}_k \) the optimal estimate and \( \hat{s}_k \) the mode of the \( p(s_k|m^k) \).

Calling Sequence:

\[
\text{CALL ERR(INDX, SDI1, SDI2, P, Q, QH1, QH2, ERR1, ERH1, ERH2, ER12)}
\]

Common Variables:

\( N, NZ, MT \) \hspace{1cm} \text{integers given in the main program.}

Input:

\begin{itemize}
  \item \textbf{INDX} \hspace{1cm}
  \begin{itemize}
    \item \text{INDX=1} \hspace{1cm} \text{If return without any computation}
    \item \text{INDX=2} \hspace{1cm} \text{If the mode of distribution in terms of Euler angles and quaternion } \hat{s}_k \text{ to be computed with error between } s_k \text{ and } \hat{s}_k.
    \item \text{INDX=3} \hspace{1cm} \text{If the maximum eigenvalue } \lambda \text{ of } E(q\cdot q^T) \text{ and its eigenvector } \hat{s}_k \text{ with the error estimate between } s_k \text{ and } \hat{s}_k \text{ in addition to the case INDX=2.}
  \end{itemize}
\end{itemize}
SDD1  3x3x17 dimensional array, \( \{d^1_{mn}(\theta)\} \)

SDD2  5x5x17 dimensional array \( \{d^2_{mn}(\theta)\} \)
both are precomputed in 'INSDD'.

SINE  33-dim. array, \( \{\sin(\phi)\} \).

COSN  33-dim. array, \( \{\cos(\phi)\} \)
both are computed in 'SINCOS'.

P, Q  2x5x5 dimensional arrays representing the Fourier
coefficients in \( p(s_k|m) \), computed in 'NPAQ'.

Output:

Q11  4-dim. array, the unit eigenvector corresponding
to the maximum eigenvalue \( \lambda', s_k' \).

Q12  4-dim. array, the mode of the distribution.

ERR1  1-\( \lambda \), where \( \lambda \) is the maximum eigenvalue of \( E(q\cdot q^T) \).

ERH1  distance between \( s_k = (q_1, q_2, q_3, q_4) \) and \( \hat{s}_k = (p_1, p_2, p_3, p_4) \) i.e.
\[ 1 - \frac{4}{\sum p_i q_i} \]

ERH2  distance between \( s_k \) and \( \hat{s}_k \).

ERI2  distance between \( s_k \), \( \hat{s}_k \).

Special Consideration

1. \( \{d^1_{mn}(\theta)\} \) and \( \{\sin(\phi), \cos(\phi)\} \) are precomputed to save
computing time.

2. To find eigenvalues and eigenvectors of symmetric matrix
\( E(q\cdot q^T) \), first the matrix is tridiagonalized by 'TRIDMX',
then eigenvalues and eigenvectors are obtained by 'EIGVAL',
'EIGVEC' in the subprogram EIGEN.

ESTIM

A Subprogram

Purpose:
1. To compute the mode and the maximum value of the function 
   \( f(\psi, \theta, \phi) \) in the conditional density function \( P(s_k|m_k) \)
2. To compute the normalizing constant for \( P(s_k|m_k) \) by local 
   integration.
3. To evaluate the maximum eigenvalue \( \lambda \) and its eigenvector 
   \( p(=\hat{s}_k) \) of the matrix \( E(q^T) \) with the conditional density 
   function \( P(s_k|m_k) \) and obtain the optimal estimation error 
   
   \[ 1 - \lambda = 1 - p^T \cdot E(q^T) \cdot p \]
4. To obtain distances \( \rho(s_k, \hat{s}_k), \rho(\hat{s}_k, \hat{s}_k), \rho(s_k, \hat{s}_k) \), where \( s_k \) 
   true quaternions, \( \hat{s}_k \) optimal estimates, \( \hat{s}_k \) maximum likelihood 
   estimates by \( P(s_k|m_k) \).

Calling Sequence:

\[ \text{CALL} \quad \text{ESTIM}(P, Q, QT, QH1, QH2, ER1, ERH1, ERH2, ER12) \]

Common Variables:

\( QS \)

Input:

\( QS \quad s_k \), real attitude, 4-dim array
\( P, Q \quad \{p_{1mn}^{ek}\}, \{p_{2mn}^{ek}\}, 2x5x5 \)-dim arrays
\( QT \quad \) predicted attitude at time \( k \), 4-dim array

Output:

\( QH1 \quad \) Optimal estimate of \( s_k, \hat{s}_k \), 4-dim array
\( QH2 \quad \) Mode of the distribution, \( \hat{s}_k \), 4-dim array
ERR1 Optimal estimation error given by 1-\( \lambda \), where \( \lambda \) is the maximum eigenvalue of \( E(q\cdot q^T) \)

ERRH1 Distance between \( s_k \) and \( \hat{s}_k \)

ERRH2 Distance between \( s_k \) and \( \hat{s}_k \)

ERRL2 Distance between \( \bar{s}_k \) and \( \bar{s}_k \)

Special Considerations:

1. To find a mode of the conditional density function, a searching method is taken.

2. To find eigenvalues and eigenvectors of a symmetric matrix, \( E(q\cdot q^T) \), the matrix is first tridiagonalized by 'TRIDMX' and then eigenvalues by 'EIGVAL', eigenvectors by 'EIGVEC' are obtained.

\end{bmatrix}
\]

where \(u_j(s)\) (or \(u_j(s)\)) is given by

\[
u_j(s) = m_j^3a_3(k)D^1_{00}(s) + [\sqrt{2}m_j^2a_2(k)ReD^1_{-10}(s) + (m_j^2a_2(k) - m_j^1a_1(k))ReD^1_{-11}(s) - \sqrt{2}m_j^1a_3(k)ReD^1_{01}(s) + (m_j^1a_3(k) + m_j^2a_2(k))ReD^1_{11}(s) + [\sqrt{2}m_j^3a_2(k)ImD^1_{-10}(s) - (m_j^1a_2(k) + m_j^2a_1(k))ImD^1_{-11}(s) - \sqrt{2}m_j^2a_3(k)ImD^1_{01}(s) + (m_j^1a_1(k) - m_j^2a_2(k))ImD^1_{11}(s)]
\]

Calling Sequence:

\[
Y = FU(K, DD, AA, BB)
\]

Common variables:

None.
Input:

K integer.  
FU = -u_1 if K=1, FU = u_3 if K=2  
FU = -\nu_1 if K=3, FU = \nu_3 if K=4  
FU = u_2 if K=5, FU = \nu_2 if K=6

\[ D(1) \]

values \{ReD_{mn}^1(s)\}, \{ImD_{mn}^1(s)\}, computed in 'DRI2', 3x3 dimensional array.

\[ AA, BB \]

coefficients of \{ReD_{mn}^1(s)\} and \{ImD_{mn}^1(s)\}, respectively, computed in 'COEFF1', 6x3x3 dimensional arrays.

Special Considerations:

None.

Other Subprogram Called:

None
GAUSS

A subprogram

Purpose:
To generate a random number from a given normal distribution $N(m, s)$ (The program is taken from IBM 360 scientific subroutine package, p.77).

Calling Sequence:
CALL GAUSS(IX, S, AM, V)

Common Variables:
No.e

Input:
IX initial random integer to create a sequence of random numbers from the uniform distribution.
S standard deviation.
AM mean

Output:
V random number from the normal distribution.

Special Consideration:
1. In the program, the mean is always assumed to be zero.

GAUSS4

A subprogram

Purpose:

To generate four independent random values from normal distributions.

Calling Sequence:

CALL GAUSS4(M, IXO, R, V)

Common Variables:

None.

Input:

M  total number of times to use RANDU to generate random values from the uniform distribution.

IXO  initial integer for RANDU.

R  \( \frac{1}{R(i)} \) representing the variance of the \( i \)-th normal distribution, \( 1 \leq i \leq 4 \).

Output:

V  random values, 4-dim. array.

Special Considerations:

1. Four random integers are chosen among \( M \) integers for \( V(1), V(2), V(3), V(4) \).

Return
INITPO

A subprogram

Purpose:

To give an initial density function for the conditional density functions \( \{P(s_k | m^k)\} ; \) e.g. \( P(s_0 | m^0) = P(s_0). \)

As an initial density \( P(s_0) \), the following type of distribution on SO(3) is chosen,

\[
P(s_0) = C \cdot \exp \left( r(a_1 q_1 + a_2 q_2 + a_3 q_3 + a_4 q_4)^2 \right)
\]

where \((a_1, a_2, a_3, a_4)\) is a constant quaternion, representing the mode, and \(s_0 = (q_1, q_2, q_3, q_4)\).

In the program \( (a_1 q_1 + a_2 q_2 + a_3 q_3 + a_4 q_4)^2 \) is expressed as an expansion of \( \{\text{Re}P_{\ell m}^1(s)\} \{\text{Im}P_{\ell m}^1(s)\} \), and the coefficients of the expansion are stored in \((P\emptyset, Q\emptyset)\).

Calling Sequence:

```
CALL INITPO (AK, A, P\emptyset, Q\emptyset)
```

Common Variables:

None

Input:

AK parameter representing the magnitude of mode of the distribution, \( r \).

A 4 dimensional array, mode \((a_1, a_2, a_3, a_4)\).

Output:

\( P\emptyset, Q\emptyset \) 2x5x5 dimensional arrays, coefficients of \( \{\text{Re}P_{\ell m}^1(s_0)\} \{\text{Im}P_{\ell m}^1(s_0)\} \), respectively.
Special Considerations:

1. The relations between \((q_1, q_2, q_3, q_4)\) and \(\{D^{1}_{mn}(s_0)\}\) are given

\[
q_1^2 = \frac{1}{4} - \left(\frac{1}{4}\right)D_{00}^{1} - \left(\frac{1}{2}\right)ReD_{-11}^{1}
\]

\[
q_2^2 = \frac{1}{4} - \left(\frac{1}{4}\right)D_{00}^{1} + \left(\frac{1}{2}\right)ReD_{-11}^{1}
\]

\[
q_3^2 = \frac{1}{4} + \left(\frac{1}{4}\right)D_{00}^{1} - \left(\frac{1}{2}\right)ReD_{-11}^{1}
\]

\[
q_4^2 = \frac{1}{4} + \left(\frac{1}{4}\right)D_{00}^{1} + \left(\frac{1}{2}\right)ReD_{-11}^{1}
\]

\[
q_1q_2 = -\left(\frac{1}{2}\right)ImD_{-11}^{1}, \quad q_1q_3 = \frac{\sqrt{2}}{4} (ReD_{-10}^{1} - ReD_{01}^{1})
\]

\[
q_1q_4 = \frac{\sqrt{2}}{4} (ImD_{-10}^{1} + ImD_{01}^{1}), \quad q_2q_3 = -\frac{\sqrt{2}}{4} (ImD_{01}^{1} - ImD_{-10}^{1})
\]

\[
q_2q_4 = \frac{\sqrt{2}}{4} (ReD_{-10}^{1} + ReD_{01}^{1})
\]

2. In the program, the north pole \((0, 0, 0, 1)\) is taken as a mode.

3. Coefficients of \(\{ReD_{mn}^{1}\}\) and \(\{ImD_{mn}^{1}\}\) are stored in \(P\Phi(1,\ldots)\) and \(Q\Phi(1,\ldots)\) respectively. By the properties of

\[
ReD_{-m-n}^{\ell} = (-1)^{n-m}ReD_{mn}^{\ell}
\]

\[
ImD_{-m-n}^{\ell} = (-1)^{n-m+1}ImD_{mn}^{\ell}
\]

The coefficients are arranged using the following signs tables:

\[
\begin{bmatrix}
1 & 1 & 1 \\
-1 & 1 & 1 \\
1 & -1 & 1
\end{bmatrix}
\]

for real parts
\[
\begin{bmatrix}
-1 & 1 & 1 \\
1 & 0 & 1 \\
1 & 1 & 1
\end{bmatrix}
\text{ for imaginary parts}
\]

Example: If the coefficient of $\text{ReD}_{01}^1$ is

\[
\frac{\sqrt{2}}{2} (-a_1 a_3 + a_2 a_4) \cdot r,
\]

then

\[
\begin{align*}
P\varnothing(1, 2, 3) &= \frac{\sqrt{2}}{2} (-a_1 a_3 + a_2 a_4) \cdot r \\
P\varnothing(1, 4, 2) &= \frac{\sqrt{2}}{2} (a_1 a_3 - a_2 a_4) \cdot r
\end{align*}
\]

this gives a term

\[
\frac{1}{2} P\varnothing(1, 2, 3) \text{ReD}_{01}^1 + \frac{1}{2} P\varnothing(1, 1, 2) \text{ReD}_{0-1}^1
\]

\[
= \frac{\sqrt{2}}{4} (-a_1 a_3 + a_2 a_4) \cdot r \text{ReD}_{01}^1 + \frac{\sqrt{2}}{4} (-a_1 a_3 + a_2 a_4) \cdot r \text{ReD}_{0-1}^1
\]

\[
= \frac{\sqrt{2}}{2} (-a_1 a_3 + a_2 a_4) \cdot r \text{ReD}_{01}^1 \text{ (since ReD}_{0-1}^1 = -\text{ReD}_{01}^1)
\]
Flow Chart

\[ \text{BEGIN} \]

\[ P\phi(1,3,3) = (a_d^2 - a_3^2)/2.0 \]
\[ P\phi(1,1,1) = P\phi(1,3,3) \]
\[ P\phi(1,2,3) = (a_2^2 - a_1^2, a_3^2) \sqrt{2}/2.0, P\phi(1,2,1) = -P\phi(1,2,3) \]
\[ P\phi(1,1,3) = (a_1^2 - a_2^2)/2.0, P\phi(1,3,1) = P\phi(1,1,3) \]
\[ P\phi(1,2,2) = (a_3^2 + a_4^2 - a_1^2 - a_2^2)/2.0 \]
\[ P\phi(1,1,2) = (a_1a_3 + a_2a_4) \sqrt{2}/2.0, P\phi(1,3,2) = -P\phi(1,1,2) \]
\[ Q\phi(1,3,3) = -a_3a_4, Q\phi(1,1,1) = -Q\phi(1,3,3) \]
\[ Q\phi(1,2,3) = -(a_1a_4 + a_2a_3) \sqrt{2}/2.0, Q\phi(1,2,1) = Q\phi(1,2,3) \]
\[ Q\phi(1,1,2) = -a_1a_2, Q\phi(1,3,1) = -Q\phi(1,1,3) \]
\[ Q\phi(1,1,2) = (a_2a_3 - a_1a_4) \sqrt{2}/2.0, Q\phi(1,3,2) = Q\phi(1,1,2) \]

\[ \text{RETURN} \]
INSDD
A subprogram

Purpose:
To generate a table for \( \{d_{mn}(\theta)\} \), where \( 1 \leq \ell \leq 2 \), \(-\ell \leq m,n \leq \ell\)

Calling Sequence:

CALL INSDD (MT, SDD1, SDD2)

Common Variables:

Input:

D
mesh size, i.e. \( D = \pi/MT \), given in the main program.

MT
number of meshes in \([0,\pi]\) (in the program \( MT=16 \)).

Output:

SDD1 3x3x17 dimensional array, \( \{d_{mn}(\theta_i)\} \)
SDD2 5x5x17 dimensional array, \( \{d_{mn}(\theta_i)\} \),
where \( \theta_i = (\pi/MT)\times(i-1) \), \( i=1,2,\ldots,(MT+1) \)

Special Considerations
1. The values \( d_{mn}^1(\theta_i) \), \( d_{mn}^2(\theta_i) \) are stored in SDD1(m+2, n-2)
   SDD1(m+2, n+2, 1) and SDD2(m+3, n+3, 1), respectively.

Other Subprograms Called:

SD.
Flow Chart

BEGIN

M1 = MT + 1

L = 1

\[ SDD1(I, J, K) = SD(L, M, N, T_k) \]
1 ≤ I ≤ 3, M = I - 2
1 ≤ J ≤ 3, N = J - 2
\[ T_k = (k-1) \cdot D, \ 1 \leq k \leq M1 \]

L = L + 1

\[ SDD2(I, J, K) = SD(L, M, N, T_k) \]
1 ≤ I ≤ 5, M = I - 3
1 ≤ J ≤ 5, N = J - 3
\[ T_k = (k-1) \cdot D, \ 1 \leq k \leq M1 \]

Return
INTGLE

A Subprogram

Purpose:

To compute the expectation $E(q \cdot q^T)$ with respect to the conditional density

$$p(s_k|m^k) = C \cdot \exp(f(s_k))$$

where:

$$f(s_k) = \sum_{k=1}^{2} \left( \frac{1}{2} p_{00}^k 100 D_0^k (s_k) + \sum_{m,n=\leq}^{\ell} (p_{mn}^k \text{Re}D_{mn}^k (s_k)$$

$$+ p_{mn}^k \text{Im}D_{mn}^k (s_k)) \right)$$

and $C$ is the normalizing constant, $q = (q_1, q_2, q_3, q_4)$ quaternion variable.

Calling Sequence:

CALL INTGLE(IND, SDD1, SDD2, SINE, COSN, P, Q, FMAX, ANG, C, QQ).

Common Variables:

MT, NZ, H, D

Input:

MT  number of meshes in $[0, \pi]$ for $\theta$
NZ  number of meshes in $[0, 2\pi]$ for $\phi$ and $\psi$
D   mesh size for $\theta$, i.e. $D = \pi / MT$
H   mesh size for $\phi$ and $\psi$, i.e. $H = 2\pi / NZ$

The above values are computed in the main program for integration.
SDD1, SDD2 3x3x17 and 5x5x17 dimensional array, representing
\{d^1_mn(\theta_i)\}, \{d^2_mn(\theta_i)\} respectively, where
\theta_i = D.(i-1), i=1, 2, ..., (MT+1).

IND integer IND=0 if \(\max(f(s_k)) (=\text{FMAX})\) on \(S0(3)\) to be
computed. IND=1 if a normalizing constant to be com-
puted and IND=2 if \(E(q\cdot q^T)\) to be computed.

SINE, COSN 33-dimensional arrays, tables of \{\sin(\phi_i)\}, \{\cos(\phi_i)\},
respectively, where \(\phi_i = H.(i-1), i=1, 2, ..., (NZ+1)\).

P, Q 2x5x5 dimensional arrays representing \{p^{ek}_{1mn}\},
\{p^{ek}_{2mn}\} respectively.
Both are computed in 'NPAQ'.

Output:
FMAX MAX(f(s)) on S0(3)
ANG 3-dimensional array representing the mode of f(s) in
terms of Euler angles.
C normalizing constant
QQ 4x4 dim array, \(E(q\cdot q^T)\).

Special Considerations
1. In order to avoid overflow of computation \(\exp(f(\phi, \theta, \psi))\),
\(f(\phi, \theta, \psi)\) is replaced by \(f - f_0\), where \(f_0 = \text{FMAX}-165.0\)
if \(\text{FMAX} \leq 165.0\), and \(f_0 = 0\) if \(\text{FMAX} 165.0\).

2. Normalizing constant C is computed to satisfy
\[ \int C \exp(f(s)-f_0) \, ds = 1 \]
3. The mode of \( f \) at \((k-1)\)th stage will be used to determine a predicted estimate of \( s_k \).

4. \( q \cdot q^T = \begin{bmatrix} q_1^2 & q_1q_2 & q_1q_3 & q_1q_4 \\ q_2q_1 & q_2^2 & q_2q_3 & q_2q_4 \\ q_3q_1 & q_3q_2 & q_3^2 & q_3q_4 \\ q_4q_1 & q_4q_2 & q_4q_3 & q_4^2 \end{bmatrix} \)

only the upper triangle part is computed.

5. For any values involving \( \text{Re}D_{mn}^l \), \( \text{Im}D_{mn}^l \), \( \sin \phi \), \( \cos \phi \), tables \( \text{SDDI}, \text{SDD2}, \text{SINE}, \text{COSN} \) are used instead of calling subprograms.

For example, to compute

\[ \text{Re}D_{mn}^l (\phi, \theta, \psi_k) = \cos \left( \frac{\pi}{2} (m-n) - (m\phi_j + n\psi_k) \right) d_{mn}^l (\theta) \]

an integer \( MN1 \) is computed, so that

\[ \text{Re}D_{mn}^l (\phi, \theta, \psi_k) = \text{COSN}(MN1) \cdot \text{SDD1}(M+2,N+2,1). \]

\( MN1 \) is determined using the following relations,

\[ \frac{\pi}{2} \rightarrow \frac{NZ}{4} \]

\[ m\phi_j + n\psi_k \rightarrow N(J-1) + N(K-1) \]

\[ \frac{\pi}{2}(m-n) - (m\phi_j + n\psi_k) \rightarrow \left\lfloor \frac{NZ}{4} \right\rfloor (M-N) - M(J-1) - N(K-1) \]

\[ = MN \mod (NZ) \]

\[ = MN \quad \text{if} \ MN \geq 0 \]

\[ MN + NZ \quad \text{if} \ MN < 0 \]

\[ \sim MN1 = MN + 1 \]
6. \( \mathbf{q} \cdot \mathbf{q}^T \) is expressed as a function matrix of Euler angles

\[
\begin{bmatrix}
(1-\cos\theta)(1+\cos(\phi-\psi))/4.0 \\
(1-\cos\theta)\sin(\phi-\psi)/4.0 & (1-\cos\theta)(1-\cos(\phi-\psi)) \\
\sin\theta(\sin\phi+\sin\psi)/4.0 & \sin\theta(\cos\psi-\cos\phi)/4.0 & (1+\cos\theta)(1-\cos(\phi+\psi))/4.0 \\
\sin\theta(\cos\psi-\cos\phi)/4.0 & \sin\theta(\sin\phi-\sin\psi)/4.0 & (1+\cos\theta)(1+\cos(\phi+\psi))
\end{bmatrix}
\]

where the entries of the upper triangle are omitted.

7. In the computation of \( \exp(f-f_0) \), \( \exp(f-f_0) \equiv 0 \)

if \( f-f_0 \leq -50.0 \) to avoid underflow.

\end{align*}
\]

\[QQ(I_1, I_2) = FR \cdot YY \cdot W(I_1, I_2) \cdot HD \]

\[1 \leq I_1 \leq I_2 \leq 4\]
INTGL2

A Subprogram

Purpose:
To compute the normalizing constant $C$ in the conditional density function

$$P(s_k|m^k) = C \cdot \exp (f(s_k))$$

and evaluate $E(q\cdot q^T)$ with respect to $P(s_k|m^k)$.

In the program, every integration is done locally around the mode of $P(s_k|m^k)$.

Calling Sequence:

CALL INTGL2 (IND, P, Q, FMAX, A, NZ, NT, NW, HØ, C, QQ)

Common Variables:

PA12

Input:

PA12 $2\pi$

IND Integer, IND=1 if a normalizing constant to be computed, IND=2 if $E(q\cdot q^T)$ to be computed.

P, Q \{P_{lmn}, P_{lmn}\}, 2x5x5-dim arrays

FMAX Maximum of $f(s)$ on $SO(3)$, obtained in \textquoteleft MAXI\textquoteright

A Starting point $(Z(1), T(1), W(1))$ for local integration, 3-dim array

NZ, NT, NW Numbers of mesh in $[Z(1), Z(2)]$, $[T(1), T(2)]$, $[W(1), W(2)]$, respectively.

HØ Initial meshsize for integration

Output:

C Normalizing constant

QQ $E(q\cdot q^T)$, 4x4-dim array
Special Considerations:

1. In order to avoid overflows of computation \( \exp(f(\phi, 0, \psi)) \).
   \( f(\phi, 0, \psi) \) is replaced by \( f-f_0 \), where \( f_0 = \text{FMAX}-165.0 \) if \( \text{FMAX} \geq 165.0 \) and \( f_0 = 0 \), if \( \text{FMAX} \leq 165.0 \). Also to avoid underflows, \( \exp(f-f_0) = 0.0 \), if \( f-f_0 \leq -50.0 \).

2. Normalizing constant \( C \) is computed to satisfy
   \[ \int C \cdot \exp(f(s)-f_0) \, ds = 1. \]

3. Local integrations are done in four steps. At each step except the last one, the Riemann integration is done numerically skipping the \( 1/3 \times 1/3 \times 1/3 \) of the original box region around the mode (center) and the skipped box region will become a new box region for the following step. The stepsize will be one half of the previous one. At the 4th step, the numerical integration is done on the whole box region without skipping the middle region.

RETURN

RETURN
MAXI
A Subprogram

Purpose:

To locate the mode of a function $f(\phi, \theta, \psi)$ in the conditional density function.

$$P(\phi, \theta, \psi) = C \exp(f(\phi, \theta, \psi)),$$
where $C$ is a normalizing constant.

Calling Sequence:

CALL MAXI (P, Q, QT, B, FMAX)

Common Variables:

PAI2

Input:

PAI2 $2\pi$
P, Q $\{P_{1mn}\}, \{P_{2mn}\}$, 2x5x5-dim arrays
QT Initial quaternion to start for searching, 4-dim array

Output:

B Mode in terms of Euler angles, 3-dim array
FMAX Value of the function $f(\phi, \theta, \psi)$ at the mode.

Special Considerations:

1. Two starting points are used to locate the mode. The first point $(A(1), A(2), A(3))$ is given by the calling program and the second point may be given by $(A(1)+\pi, A(2)+\pi/2, A(3)+\pi)$. This is to avoid locating a local maximum instead of the global maximum.

MØ6PLT

Main program

Purpose:

To read process: \{s_k\}, \{\hat{s}_k\}, \{\hat{s}_k\} and sequences of error estimates from the disk and draw graphs.

Common Variables:

None.

Input:

A 1742-dim. array containing all the values.

Special Considerations:

1. Processes \(s_k, \hat{s}_k, \hat{s}_k\) are called QSN, QH1, QH2 in MØ5S03 and stored in the location.
   - \(A(568) \rightarrow QSN(1,1)\)
   - \(A(768) \rightarrow QH1(1,1)\)
   - \(A(968) \rightarrow QH2(1,1)\)

2. Optimal estimate errors, \(\rho(s_k, \hat{s}_k)\), and \(\sigma(s_k, \hat{s}_k)\), \(\rho(\hat{s}_k, \hat{s}_k)\) are called ERRN, ERH1, ERH2, ER12 in MØ5S03 and stored in the location
   - \(A(268) \rightarrow ERRN(1)\)
   - \(A(318) \rightarrow ERH1(1)\)
   - \(A(368) \rightarrow ERH2(1)\)
   - \(A(418) \rightarrow ER12(1)\)

3. Quaternion representation QSN, QH1, QH2 of \(s_k, \hat{s}_k, \hat{s}_k\) are modified so that 4th component of each quaternion is positive.

RETURN
QIN

A Subroutine

Purpose:

To transform Euler angles to a quaternion.

Calling sequence

CALL QIN(A, Q)

Common Variables

None.

Input

A  Euler angles (\(\phi, \theta, \psi\)), 3-dim. array.

Output

Q  Quaternion \((q_1, q_2, q_3, q_4)\), 4-dim. array.

Special Considerations

1. The formula for the transformation is given by:

\[
\begin{align*}
q_1 &= \sin \frac{\theta}{2} \cos \frac{\phi - \psi}{2} \\
q_2 &= \sin \frac{\theta}{2} \sin \frac{\phi - \psi}{2} \\
q_3 &= \cos \frac{\theta}{2} \sin \frac{\phi + \psi}{2} \\
q_4 &= \cos \frac{\theta}{2} \cos \frac{\phi + \psi}{2}
\end{align*}
\]
Flow Chart

\[
\begin{align*}
q_1 &= \sin^2 \frac{\theta}{2} \cos \frac{\phi}{2} \cos \frac{\psi}{2} \\
q_2 &= \sin \frac{\theta}{2} \sin \frac{\phi}{2} \cos \frac{\psi}{2} \\
q_3 &= \cos \frac{\theta}{2} \sin \frac{\phi}{2} \sin \frac{\psi}{2} \\
q_4 &= \cos \frac{\theta}{2} \cos \frac{\phi}{2} \sin \frac{\psi}{2}
\end{align*}
\]

Return
A subprogram

Purpose:

To compute the distance between two quaternions.

Calling Sequence:

CALL QVQ(D, Q, P)

Common Variables:

None

Input:

P, Q quaternions, 4-dim. arrays.

Output:

D distance between P and Q.

Special Consideration:

1. Distance between two quaternions p and q is given by

\[ d = 1 - \sum_{i=1}^{4} p_i \cdot q_i, \text{ where } p = (p_1, p_2, p_3, p_4) \]

\[ q = (q_1, q_2, q_3, q_4) \]

Other Subprograms Called:

None.
Flow Chart

BEGIN

\[ D = 1 - \sum_{i=1}^{4} p_i q_i \]

Return
QXQ

A subprogram

Purpose:
To compute the product of two quaternions

\[(r_1, r_2, r_3, r_4) = (P_1, P_2, P_3, P_4) \cdot (q_1, q_2, q_3, q_4),\]

where

\[r_1 = P_1 q_4 + P_2 q_3 - P_3 q_2 + P_4 q_1\]
\[r_2 = P_1 q_3 + P_2 q_4 + P_3 q_1 + P_4 q_2\]
\[r_3 = P_1 q_2 - P_2 q_1 + P_3 q_4 + P_4 q_3\]
\[r_4 = -P_1 q_1 - P_2 q_2 - P_3 q_3 + P_4 q_4\]

Calling Sequence:

CALL QXQ(P, Q, R)

Common Variables:
None.

Input:

P  quaternion \((P_1, P_2, P_3, P_4)\), 4-dim. array.
Q  quaternion \((q_1, q_2, q_3, q_4)\), 4-dim. array.

Output:

R  quaternion \((r_1, r_2, r_3, r_4)\), 4-dim. array.

Special considerations

1. Considering computer round-off error, product quaternion R is re-normalized.
Flow Chart

BEGIN

\[ r_1 = p_1 q_4 + p_2 q_3 + p_3 q_2 + p_4 q_1 \]
\[ r_2 = -p_1 q_5 + p_2 q_4 + p_3 q_3 + p_4 q_2 \]
\[ r_3 = p_1 q_2 + p_2 q_1 + p_3 q_4 + p_4 q_3 \]
\[ r_4 = -p_1 q_6 + p_2 q_2 + p_3 q_3 + p_4 q_4 \]

\[ W = \sqrt{R^2(1) + R^2(2) + R^2(3) + R^2(4)} \]

Normalization

\[ R(1) = \frac{R(1)}{W} \]
\[ R(2) = \frac{R(2)}{W} \]
\[ R(3) = \frac{R(3)}{W} \]
\[ R(4) = \frac{R(4)}{W} \]

Return
RANDU

A subprogram

Purpose:

To compute a pseudorandom integer and value of uniform distribution.

The program uses the properties of FORTRAN IV and its admissible maximum integer $2^{31} - 1$ (=2147483647) and overflows, (the program is taken from IBM 360 scientific subroutine, p.77).

Calling Sequence:

CALL RANDU(IX, IY, YFL)

Common Variables:

None.

Input:

IX integer

Output:

IY pseudorandom integer

YFL pseudorandom value, $YFL = IY/(2^{31} - 1)$

Special Considerations:

1. To generate a sequence of pseudorandom numbers RANDU can be used repeatedly by setting $IX = IY$. 
Flow Chart

BEGIN

IY = 1X·65539

N

IY ≥ 0

Y

IY = IY + 2147483647 + 1

YFL = IY

YFL = YFL·0.4656613 x 10^-9

Return.
SINCOS

A subroutine

Purpose

To construct numerical tables of \( \sin x \) and \( \cos x \) for \( 0 \leq x \leq 2\pi \)

Calling Sequence:

\[
\text{CALL SINCOS}(N, \text{SINE}, \text{COSN})
\]

Common Variables:

None

Input:

\( N \) Number of points in \([0, 2\pi]\) to be taken

Output:

\( \text{SINE} \) values \( \{\sin x_i\} \), \( N \)-dim. array

\( \text{COSN} \) values \( \{\cos x_i\} \), \( N \)-dim. array

Special Considerations:

1. Tables are used to reduce computing time.

2. In order to avoid future underflows,

\[
\text{if } |\text{SINE}(i)| \cdot |\text{COS}(i)| < 10^{-11}, \text{ then }
\]

\[
\text{SINE}(i) = 0, \text{ COS}(i) = 0
\]

Other Subprograms Called:

None.
Flow Chart

BEGIN

\[ \Pi_{12} \approx 6.28318536 + 0.86 \]
\[ \epsilon_{1} \approx 1 \times 10^{-10} \]

\[ \Phi = \Pi - 1 \]
\[ h = 2\pi / \Phi \]
\[ i = 1 \]

\[ x_i = (i-1) \cdot h \]

\[ \text{SINE}(i) = \sin(x_i) \]

\[ \text{COSN}(i) \nleq \epsilon_{1} \]
\[ \text{Y} \]
\[ \text{COSN}(i) = 0.0 \]
\[ i = i + 1 \]

\[ \text{N} \]
\[ i > N \]
\[ \text{Y} \]

Return

\[ \text{N} \]
\[ \text{SINE}(i) \nleq \epsilon_{1} \]
\[ \text{Y} \]
\[ \text{SINE}(i) = 0.0 \]

\[ \text{N} \]
\[ \text{COSN}(i) = \cos(x_i) \]
SD

A subroutine

Purpose:

To assign values \( d_{mn}^l(T) \) to each \( l, m, n \) and \( 0 \leq T \leq \pi \).

Calling Sequence:

\[ Y = SD(I.,M,N,T) \]

Input:

\( L \) order of Fourier coefficients to be computed

\( M, N \) indices of Fourier coefficients with the range

-\( L \leq M, N \leq L \)

\( T \) angle \( 0 \leq T \leq \pi \)

Special Considerations:

1. \( L, M, N \) must satisfy the relations

\[ 0 \leq L \leq LMAX \text{ and } -L \leq M, N \leq L \]

Other Subprograms Called:

FR
BEGIN

\[ M_1 = M - N \]
\[ M_2 = I + M \]
\[ M_3 = I + N \]

\[ M_L = \text{MAX}(M_1, 0) \]
\[ M_U = \text{MIN}(M_2, M_3) \]
\[ M_M = M_U - M_L + 1 \]

\[ \text{SD} = 0.0 \]

\[ A_t = \left\{ \frac{1}{(\ell + m)! (\ell - m)! (\ell + n)! (\ell - n)!}\right\}^{\frac{1}{2}} \]
\[ B_t = (\ell + m - t)! (t + n - m)! t! (\ell - n - t)! \]
\[ \text{SD} = \sum_{\text{MU}} \frac{A_t}{B_t} \cdot \cos \left( \frac{2\ell + m - n - 2t}{2} (\frac{TT}{T}) \right) \]
\[ \cdot \sin \left( \frac{2t + n - m}{2} (\frac{TT}{T}) \right) \]

RETURN
SEARCH

a subroutine

Purpose:
To find the mode of the conditional density function with a given initial starting point and mesh size.

Calling sequence:
CALL SEARCH (DMESH, NF, P, Q, A, B, S1)

Common Variables:

PA12

Input:

PA12  2n
DMESH  Stepsize to search the maximum value of the density function.
NF  Maximum searching times in one direction at the previous stage.
P, Q  {P^k, P^k}, 2x5x5-dim arrays
A  Starting point (Euler angles), 3-dim array
S1  Value of f(φ, 0, Ψ) at A

Output:

B  Maximum point (mode) of the function f(φ, 0, Ψ) with respect to the given mesh
S1  Maximum value of f(φ, 0, Ψ)
NF  Maximum searching times at this stage, which will be used in calling program 'MAXI' to determine the new mesh size

Special Considerations:

1. Searching the mode continues as long as the previous function value is less than the new value.
BEGIN

B(i) * A(i)

i = 1

Y: k = k + 1

S1 = S2

B(i) * B(i) - SN * DMESH

Y: k = 1

SN < Ø

Y: NF < k

NF = k
A subprogram

Purpose:

1. To store processes
   \( \{s_i\} \{\hat{s}_i\} \{\hat{s}_i\} \quad 1 \leq i \leq (k-1) \), where \( \{s_i\} \)
   are attitudes, \( \{\hat{s}_i\} \) attitude estimates, \( \{\hat{s}_i\} \) maximum
   likelihood estimates, and
   \[
   \text{ERRN}(i) = \mathbb{E}(\rho(s_i, \hat{s}_i)), \quad \text{ERH1}(i) = \rho(s_i, \hat{s}_i),
   \]
   \[
   \text{ERH2}(i) = \rho(s_i, \hat{s}_i) \quad \text{ER12}(i) = \rho(\hat{s}_i, \hat{s}_i).
   \]

2. To save the values of the parameters for the next step \( k \).

3. To read all the results from disk and printout if requested.

Calling Sequence:

\[
\text{CALL TRANS}(\text{ID, IX0, IY0, KK, MM})
\]

Common Variables:

\[
\text{AXX, AD, AA, BB, W0, OBN, P0, Q0, AK, DIR, QW, QSN, QH1, QH2, ERRN, ERH1, ERH2, ER12, SINE, COSN}
\]

Input:

\( \text{ID} \) indicator
- the values are to be stored in the disk if \( \text{ID}=1 \).
- the values are to be read from the disk if \( \text{ID}=2 \) or \( 3 \). If \( \text{ID}=3 \), the results are printed.

\( \text{AXX, AD, AA, BB, W0, OBN, P0, Q0, AK, DIR, QW, QSN, QH1, QH2, ERRN, ERH1, ERH2, ER12, SINE, COSN} \), given in the main program.

\( \text{IX0} \) integer, the last integer used to create a random integer by \text{RANDU}.

\( \text{IY0} \) integer, the last integer used to create another random integer by \text{RANDU}.
KK time $k$ at which all the result should be updated.

$MM$ integer, $(M-1)$ values are stored for each QSN, QH1, QH2, ERRN, ERH1, ERH2, ER12 for the output purpose.

Output:

$AXX, AD, AA, BB, W\xi, P\phi, Q\phi, AK, DIR, QW, QSN, QH1, QH2, ERRN, ERH1, ERH2, ER12, SINE, COSN, IX\phi, IY\phi, KK, MM$.  

Special Considerations

1. For the use of disk, variables A, B are used to store results with

   $A(1742), B(871, 2), EQUIVALENCE(A(1), B(1,1))$.

2. All the values are stored in A in the following order.

   $\begin{align*}
   A(1): & \quad KK \\
   A(2): & \quad MM \\
   A(3): & \quad 1X\phi \\
   A(4): & \quad 1Y\phi \\
   A(5): & \quad AK \\
   A(11): & \quad AXX91,1,1 (18)* \\
   A(29): & \quad AD(1,1) (6) \\
   A(35): & \quad AA(1,1,1) (S4) \\
   A(89): & \quad BB(1,1,1) (S4) \\
   A(143): & \quad RR(1) (6) \\
   A(149): & \quad DIR(1) (4) \\
   A(153): & \quad W\phi(1) (3) \\
   A(156): & \quad QW(1) (4) \\
   A(160): & \quad QS(1) (4) \\
   A(164): & \quad QH\phi(1) (4)
   \end{align*}$

   * $1^q = 2x3x3$ representing the array of $AXX$ and $A(11)$ corresponds to $AX (1,1,1)$.

Return
TRIDMX

A subprogram

Purpose:

To transform a real symmetric matrix to tridiagonal form using Householder's method.

Calling sequence:

CALL TRIDMX(N, NM, A, D, B)

Common Variables:

None.

Input:

N   number of rows and columns in matrix A
    Also N is the number of elements in D and B

NM   Maximum number of rows A can have as specified by the DIMENSION statement in the calling program.

A   NXN-dimensional array containing the symmetric matrix.

Output:

D   array containing the diagonal elements of the tridiagonal matrix.

B   array containing the off-diagonal elements of the tridiagonal elements of the tridiagonal matrix in locations B(2) through B(N). B(1)=0.0.

Special Considerations:

1. The lower triangular half of A is changed by TRIDMX.

2. TRIDMX is designed to be used with EIGVAL and EIGVEC.

Other Subprograms Called:

None.

Return
UPDWN

A subprogram:

Purpose:

To obtain maximum or minimum of two values.

Calling Sequence:

UPDWN(ID, X, Y)

Common Variables:

None.

Input:

ID integer, if, ID=1, minimum, if, ID=2, maximum of two values X and Y to be computed.

X, Y two values

Special Consideration:

None.

Other Subprograms Called:

None.
Flow Chart

BEGIN

UPDWN=X

ID=1

X < Y → Y

UPDWN=Y

Return
An optimal estimation scheme is presented, which determines the satellite attitude using the gyro readings and the star tracker measurements of a commonly used satellite attitude measuring unit. The scheme is mainly based on the exponential Fourier densities that have the desirable closure property under conditioning. By updating a finite and fixed number of parameters, the conditional probability density, which is an exponential Fourier density, is recursively determined.
Simulation results indicate that the scheme is effective and robust. It is believed that this approach is applicable to many other attitude measuring units. As no linearization and approximation are necessary in the approach, it is ideal for systems involving high levels of randomness.

When a system involves little randomness and linearization is not expected to incur much error, the approach can provide a benchmark against which such suboptimal estimators as the extended Kalman filter and the least-squares estimator can be compared. In this spirit, simulated data for HEAO-A were processed to compare the optimal scheme and the extended Kalman filter. The results are presented.
