This paper reports on an experiment in trying to understand an unfamiliar program of some complexity and to record the authors' understanding of it. The goal was to stimulate a practicing programmer in a program maintenance environment using the techniques of program design adapted to program understanding and documentation; that is, given a program, a specification and correctness proof were developed for the program. The approach points out the value of correctness proof ideas in guiding the discovery process. Toward this end, a variety of techniques were used; direct cognition for smaller parts, discovering and

verifying loop invariants for larger program parts, and functions determined by additional analysis for larger program parts. An indeterminate bounded variable was introduced into the program documentation to summarize the effect of several program variables and simplify the proof of correctness.
ABSTRACT

This paper reports on an experiment in trying to understand an unfamiliar program of some complexity and to record the authors' understanding of it. The goal was to simulate a practicing programmer in a program maintenance environment using the techniques of program design adapted to program understanding and documentation; that is, given a program, a specification and correctness proof were developed for the program. The approach points out the value of correctness proof ideas in guiding the discovery process. Toward this end, a variety of techniques were used: direct cognition for smaller parts, discovering and verifying loop invariants for larger program parts, and functions determined by additional analysis for larger program parts. An indeterminate bounded variable was introduced into the program documentation to summarize the effect of several program variables and simplify the proof of correctness.

I. INTRODUCTION

Understanding programs - We report here on an experiment in trying to understand an unfamiliar program of some complexity and to record our understanding of it. We are as much concerned with recording our understanding as with understanding. Every day programmers are figuring out what existing programs do more or less accurately. But most of this effort is lost, and repeated over and over, because of the difficulty of capturing this understanding on paper. We want to demonstrate that the very techniques of good program design can be adapted to problems of recording hard won understandings about existing programs.

In program design, we advocate the joint development of design and correctness proof, as shown by Dijkstra in (Dahl, Dijkstra, and Hoare) and (Dijkstra) and by (Linger, Mills, and Witt), rather than a posteriori proof development. Nevertheless, we believe that the idea of program correctness provides a comprehensive a posteriori strategy for developing and recording an understanding of an existing program. In fact, we advocate another kind of joint development, this time, of specification and correctness proof. In this way, we have a consistent approach dealing always with three objects; namely, (1) a specification, (2) a program, and (3) a correctness proof. In writing a program, we are given (1) and develop (2) and (3) jointly; in reading a program, we are given (2) and develop (1) and (3) jointly. In either case, we end up with the same harmonious arrangement of (1) and (2) connected by (3) which contains our understanding of the program.

In the experiment at hand, our final understanding exceeded our most optimistic initial expectations, even though we have seen these ideas succeed
before. One new insight from this experiment was how little we really had to know about the program to develop a complete understanding and proof of what it does (in contrast to how it does it). Without the correctness proof ideas to guide us, we simply would not have discovered how little we had to know. In fact, we know a great deal more than we have recorded here about how the program works, which we chalk up to the usual dead ends of a difficult discovery process. But the point is, without the focus of a correctness proof, we would still be trying to understand and record a much larger set of logical facts about the program than is necessary to understand precisely what it does.

In retrospect, we used a variety of discovery techniques. For simpler parts of the program, we used direct cognition. In small complex looping parts, we discovered and verified loop invariants. In the large, we organized the effect of major program parts as functions to be determined by additional analysis. We also discovered a new way to express the effect of a complex program part by introducing a bounded indeterminate variable which radically simplified the proof of correctness of the program part.

The experiment - We were interested in a short but complex program using real arithmetic, and felt that more attention might be paid to the structure and correctness of programs that deal with real arithmetic. The program was chosen by Professor James Vandergraft of the University of Maryland as a difficult program to understand. It was a FORTRAN program called ZEROIN which claimed to find a zero of a function given by a FORTRAN subroutine.

Our goal was to simulate a practicing programmer in a program maintenance environment. We were given the program and told its general function. The problem then was to understand it, verify its correctness, and possibly modify it, to make it more efficient or extend its applicability. We were not given any more about the program than the program itself. The program given
to us is shown in Figure 1. Professor Vandergraft played the role of a user of the program and posed four questions regarding the program:

1. I have a lot of equations, some of which might be linear. Should I test for linearity and then solve the equation directly, or just call ZEROIN? That is, how much work does ZEROIN do to find a root of a linear function?

2. What will happen if I call ZEROIN with FA and FB both positive? How should the code be changed to test for this condition?

3. It is claimed that the inverse quadratic interpolation saves only .5 function evaluations on the average. To get a shorter program, I would like to remove the inverse quadratic interpolation part of the code. Can this be done easily? How?

4. Will ZEROIN find a triple root?

It should be noted that the authors are not currently working in the area of numerical analysis, though it is not an unknown area to them.

***** ZERODV. INFD *****

ZERODV IS A FUNCTION SUBPROGRAM WHICH FINDS
A ZERO OF THE FUNCTION F(X) IN THE INTERVAL AX, BX.
THE CALLING STATEMENT SHOULD HAVE THE FORM

X* = ZERODV(AX, BX, F, TOL, IP)

WHERE THE PARAMETERS ARE DEFINED AS FOLLOWS.

INPUT

AX
LEFT ENDPOINT OF INITIAL INTERVAL
BX
RIGHT ENDPOINT OF INITIAL INTERVAL
F
FUNCTION SUBPROGRAM WHICH EVALUATES F(X) FOR ANY X IN
THE INTERVAL AX,BX
TOL
DESIRED LENGTH OF THE INTERVAL OF UNCERTAINTY OF THE
FINAL RESULT ( .GE. 0.3)
IP
AN INTEGER PRINT FLAG. WHEN SET TO 0, NO PRINTING
WILL BE DONE BY ZERODV. IF SET TO 1, THEN
ALL OF THE INTERVALS COMPUTED BY ZERODV WILL
BE PRINTED OUT.

OUTPUT

ZERODV ABCISSA APPROXIMATING A ZERO OF F IN THE INTERVAL AX,BX

IT IS ASSUMED THAT F(AX) AND F(BX) HAVE OPPOSITE SIGNS
WITHOUT A CHECK. ZERODV RETURNS A ZERO X IN THE GIVEN INTERVAL
AX,BX TO WITHIN A TOLERANCE 4 * CHIPS * ABS(X) + TOL, WHERE CHIPS
IS THE RELATIVE MACHINE PRECISION.

THIS FUNCTION SUBPROGRAM IS A SLIGHTLY MODIFIED TRANSLATION OF
THE ALGOL 60 SUBROUTINE ZERODV GIVEN IN RICHARD BRENTH, ALGORITHMS FOR
MINIMIZATION WITHOUT DERIVATIVES, PRENTICE-HALL, INC. (1972). THIS
VERSION IS ADAPTED FROM "COMPUTER METHODS FOR MATHEMATICAL
COMPUTATIONS" BY FORDYKE, HALL, AND STOOG. THE ONLY CHANGE
IS THE INCLUSION OF THE PRINT FLAG IP.

Figure 1. (Page 2)
II. TECHNIQUES FOR UNDERSTANDING PROGRAMS

Flowcharts - Any flowchartable program can be analyzed in a way we describe next for better understandability and documentation. For a fuller discussion, see (Linger, Mills and Witt). We consider flowcharts as directed graphs with nodes and lines. The lines denote flow of control and the nodes denote tests and operations on data. Without loss of generality, we consider flowcharts with just three types of nodes, namely:

- **function node:**
- **predicate node:**
- **collecting nodes:**

where \( f \) is any function mapping the data known to the program to new data, e.g., a simple FORTRAN assignment statement, and \( p \) is any predicate on the data known to the program, e.g., a simple FORTRAN test. An **entry line** of a flowchart program is a line adjacent to only one node, at its head; an **exit line** is adjacent to only one node, its tail.

**Functions and data assignments** - Any function mapping the data known to a program to new data can be defined in a convenient way by generalized forms of data assignment statements. For example, an **assignment**, denoted

\[
x := e, \quad (\text{e.g., } x := x + y)
\]

where \( x \) is a variable known to the program and \( e \) is an expression in variables known to the program, means that the value of \( e \) is assigned to \( x \). Such an assignment also means that no variable except \( x \) is to be altered. The **concurrent assignment**, denoted

\[
x_1, x_2, \ldots, x_n := e_1, e_2, \ldots, e_n
\]

means that expressions \( e_1, e_2, \ldots, e_n \) are evaluated independently, and their
values assigned simultaneously to x1, x2, ..., xn, respectively. As before, the absence of a variable on the left side means that it is unchanged by the assignment.

The **conditional assignment**, denoted

$$(p_1 \rightarrow A_1 \mid p_2 \rightarrow A_2 \mid ... \mid p_n \rightarrow A_n)$$

where $p_1, p_2, ..., p_n$ are predicates and $A_1, A_2, ..., A_n$ are assignments (simple, concurrent or conditional) means that particular assignment $A_i$ associated with the first $p_i$, if any, which evaluates true; otherwise, if no $p_i$ evaluates true, then the conditional assignment is undefined.

An expression in an assignment may contain a function value, e.g.,

$$x := \text{max}(x, \text{abs}(y))$$

where max and abs are functions. But the function defined by the assignment statement is different, of course, from max or abs.

We note that many programming languages permit the possibility of so-called side effects, which alter data not mentioned in assignment statements or in tests. Side effects are specifically prohibited in our definition of assignments and tests.

**Proper programs** - We define a **proper program** to be a program whose flow-chart has exactly one entry line, one exit line, and, further, for every node a path from the entry through that node to the exit. For example,

![Flow charts]

are proper programs, but

![Flow charts]

are not proper programs.
Program functions - We define a program function of a proper program $P$, denoted $\langle P \rangle$, to be the function computed by all possible executions of $P$ which start at its entry and terminate at its exit. That is, a program function $\langle P \rangle$ is a set of ordered pairs, the first member being a state of the data on entry to $P$, the second being the resulting state of the data on exit. Note that the state of data includes input, output files which may be read from or written to intermittently during execution. Also note that if a program does not terminate by reaching its exit line from some initial data at its entry, say by looping indefinitely or by aborting, no such pair will be determined and no trace of this abnormal execution will be found in its program function.

Proper programs are convenient units of documentation. Their program functions abstract their entire effect on the data known to the program. Within a program, any subprogram which is proper can be also abstracted by its program function, that is, the effect of the subprogram can be described by a single function node whose function is the program function of the subprogram.

We say two programs are function equivalent if their program functions are identical. For example, the programs

\begin{align*}
\begin{array}{c}
\text{f} \\
\text{f} \\
\text{p} \\
\text{f} \\
\end{array}
\end{align*}

have different flowcharts but are function equivalent.

Prime programs - We define a prime program to be a proper program which contains no subprogram which is proper except for itself and function nodes. For example,

\begin{align*}
\begin{array}{c}
\text{f} \\
\text{f} \\
\text{g} \\
\text{p} \\
\text{f} \\
\text{p} \\
\end{array}
\end{align*}

are primes, while

\begin{align*}
\begin{array}{c}
\text{f} \\
\text{g} \\
\text{h} \\
\text{p} \\
\text{f} \\
\text{g} \\
\end{array}
\end{align*}
are not prime (composite programs), the first (of the composites) having subprograms

\[ f \rightarrow g \quad \text{and} \quad g \rightarrow h \]

Any composite program can be decomposed into a hierarchy of primes, a prime at one level serving as a function node at the next higher level. For example, the composite programs above can be decomposed as shown next.

In each case, a prime is identified to serve as a function node in another prime at the next level. Note also that the first composite can also be decomposed as

\[ f \rightarrow g \rightarrow h \]

so that the prime decomposition of proper programs is not necessarily unique.

Prime programs in text form - There is a striking resemblance between prime programs and prime numbers, with function nodes playing the node of unity, and subprograms the role of divisibility. Just as for numbers, we can enumerate the control graphs of prime programs and give a text description of small primes as follows:
Larger primes will go unnamed here, although the case statement of 
Pascal is a sample of a useful larger prime. All of the primes above except 
the last (dowhiledo) are common to many programming languages. Prime programs 
in text form can be displayed with standard indentation to make the subprogram 
structure and control logic easily read, which we will illustrate for ZEROIN.
III. UNDERSTANDING ZEROIN

The prime program decomposition of ZEROIN - Our first step in understanding ZEROIN was to develop a prime program decomposition of its flowchart. After a little experimentation, the flowchart for ZEROIN was diagrammed as shown in Figure 2. The numbers in the nodes of the flowchart represent contiguous segments of the FORTRAN program of Figure 1, so all lowest level sequence primes are already identified and abstracted.

The flowchart program of Figure 2 was then reduced, a step at a time, by identifying primes therein and replacing each such prime by a newly numbered function node, e.g., R.2.3 names prime 3 in reduction 2 of the process. This reduction is shown in Figure 3, leading to a hierarchy of 6 levels. Of all primes shown in Figure 3, we note only two which contain more than one predicate, namely, R.3.1 and R.5.1, and each of these is easily modified into a composite made up of primes with no more than one predicate. These modifications are shown in Figure 4. We continue the reduction of these new composite programs to their prime decompositions in Figure 5. In each of these two cases, a small segment of programs is duplicated to provide a new composite which clearly executes identically to the prime. Such a modification which permits a decomposition into one predicate primes is always possible, provided an extra counter is used. In this case, it was fortunate that no such counter was required. It was also fortunate that the segments duplicated were small; otherwise, a program call in two places to the duplicated segment might be a better strategy.

A structured design of ZEROIN - Since a prime program decomposition of a program equivalent to ZEROIN has been found with no primes of more than one predicate, we can reconstruct this program in text form in the following way:

The final reduced program of ZEROIN is given in Reduction 6 of Figure 3, namely,

that R.6.1 is a sequence, repeated here,

R.6.1 =
\[ \begin{array}{c}
R.2.1 \\
R.5.1 \\
100-102
\end{array} \]

Now R.2.1 can be looked up, in turn, as:

R.2.1 =
\[ \begin{array}{c}
1-9 \\
R.1.1 \\
16-21
\end{array} \]

etc., until all intermediate reductions have been eliminated. Recall that R.5.1 (and R.3.1) was further reduced in Figure 5. When these intermediate reductions have all been eliminated, we obtain a structured program in PDL (Process Design Language) for ZEROIN shown in Figure 6. Note there are three columns of statement numberings. The first column holds the PDL statement number; the second holds the FORTRAN line numbering of Figure 1; the third holds the FORTRAN statement numbering of Figure 1. The FORTRAN comments have been kept intact in the structured program and appear within square brackets \[,\]. From here on, statement numbers refer to the PDL statements of Figure 6.

The duplication of code introduced in Figure 4 can be seen in PDL 72, 73, and PDL 96-99. It should be noted, however, that in PDL 87-91 the second IF STATEMENT in FORTRAN 93 can be eliminated by use of the if-then-else. This permits an execution time improvement to the code. A second improvement can be seen in PDL 62-66. The use of the absolute value function can be eliminated and the if-then-else can be used to transform the else negative \( p \) into a positive \( p \) only in the case where \( p \) is negative.

Figure 6. (2 of 2 pages)
By construction, the PDL program of Figure 6 is function equivalent to the FORTRAN program of Figure 1. But the PDL program will be simpler to study and understand.

**Data references in ZEROIN** - Our next step in understanding ZEROIN was to develop a data reference table for all data identifiers. While straightforward and mechanical, there is still much learning value in carrying out this step, in becoming familiar with the program in the new structured form. The results are given in Figure 7. This familiarization led to the following observations about the data references in ZEROIN (in no particular order of significance, but as part of a chronological, intuitive, discovery process):

1. \(ax, bx, f, ip, tol\) are never set, as might be expected, since they are all input parameters (but this check would determine initialized data if it existed, and also checks for the presence of side effects by the program on its parameters if passed by reference).

2. Zeroin is never used, but is returned as the purported zero found for \(f\) (since Zeroin is set to \(b\) just before the return of the program, it appears that \(b\) may be a candidate for this zero during execution).

3. \(eps\) is set by the dountil loop 6-11 at the start of program execution, then used as a constant at statement 36 from then on.

4. \(tol\) is used for two different unrelated purposes, namely, as a temporary in the dountil look 6-11 which sets \(eps\), then reset at statement 36 as part of a convergence consideration.

5. the function \(f\) is called but three times, at 16, 17 to initialize \(fa, fb\), and at 92 to reset \(fb\) to \(f(b)\) (more evidence that \(b\) is the candidate zero to be returned).

6. the identifiers \(a, c\) are set to and from \(b\), and the triple \(a, b, c\) seems to be a candidate for bracketing the zero which \(b\) (and zeroin) purports to approach.

Figure 7.
7. the identifiers \( f_a, f_b, f_c \) are evidently standins for \( f(a), f(b), f(c) \), and serve to limit the calls on function \( f \) to a minimum.

8. the identifiers \( p, q, r, s \) are initialized and used only in the section of the program that the comments indicate is concerned with interpolation.

9. focusing on \( b \), aside from initialization at statement 15, and as part of a general exchange among \( a, b, c \) at statement 28-29, \( b \) is updated only in the ifthenelse 83-90, incremented by either \( d \) or \( tol \).

10. \( d \) is set to \( x_m \) or \( p/q \) (as a result of a more complex bisection and interpolation process); \( x_m \) is set only at statement 37 to the half interval of \( (b, c) \) and appears to give a bisection value for \( b \).

A function decomposition of ZEROIN - The prime program decomposition and the familiarity developed by the data reference tabulation and observations suggest the identification of various intermediate prime or composite programs in playing important roles in summing up a functional structure for ZEROIN. Each such intermediate prime or composite program computes values of a function. The inputs (function arguments) of this function are defined by the initial values of all identifiers which are inputs (function arguments) for statements which make up the intermediate program. The outputs (function values) of this function are defined by the final values of all identifiers which are outputs (function values) for statements which make up the intermediate program. Of course, further analysis may disclose that such a function is independent of some inputs, if, in fact, such an identifier is always initialized in the intermediate program before its use.

On the basis of this prime decomposition and data analysis, we reformulated ZEROIN of Figure 6 as zeroinl, a sequence of four intermediate programs, as
shown in Figure 8, with function statements using the form \( f. n-m \) where \( n, m \) are the boundary statements of the intermediate programs of ZEROIN from Figure 6. The identifier *outfile in the output lists refers to the fact that data is being transferred to an outfile by an intermediate program. The phrase \((x,z,v)\) projection of some function \( x,y,z,u,v,w := p,q,r,s,t,u \) means the new function \( x,z,v := p,r,t \).

In the program descriptions which follow, all arithmetic operations are assumed to represent machine arithmetic. However, we will occasionally apply normal arithmetic axioms in order to simplify expressions. We next look at the intermediate programs.

\( f.5-11 \) - The intermediate program which computes the values of \( f.5-11 \) is a sequence, namely, an initialized dountil, i.e.

\[
\begin{align*}
5 & \quad \text{eps} := 1.0 \\
6 & \quad \text{do} \\
7 & \quad \text{eps} := \text{eps}/2.0 \\
8 & \quad \text{tol 1} := 1.0 + \text{eps} \\
9 & \quad \text{until} \\
10 & \quad \text{tol 1} \leq 1 \\
11 & \quad \text{od}
\end{align*}
\]

After some thinking, we determined that at PDL 6, an invariant of the form

\[
I_6 = (\exists k \geq 0 (\text{eps} = 2^{-k}) \land 1 + \text{eps} > 1)
\]

must hold, since entry to PDL 6 must come from PDL 5 or PDL 10 (and in the latter case \( \text{tol 1} > 1 \), having just been set to \( 1.0 + \text{eps} \), so \( 1.0 + \text{eps} > 1 \)).

Furthermore, at PDL 9 the invariant

\[
I_9 = (\exists k \geq 1 (\text{eps} = 2^{-k}) \land \text{tol 1} = 1 + \text{eps})
\]

must hold, by observing the effect of PDL 7, 8 on the invariant \( I_6 \) at PDL 6. Therefore, at exit (if ever) from the segment PDL 5-11, we must have the condition \( I_9 \land \text{PDL 10} \), namely

\[
(\exists k \geq 1 (\text{eps} = 2^{-k}) \land 1 + 2 \text{ eps} > 1 \land \text{tol 1} = 1 + \text{eps} \leq 1)
\]
func zeroin l (real ax, bx, f, tol, integer ip)

real a, b, c, d, e, eps, fa, fb, fc, p, q, r, s, tol, xm
integer ip

[compute eps, the relative machine precision]
eps, tol 1 := f. 5-11

[initialize data]
a, b, c, d, e, fa, fb, fc, *outfile := f. 13-22 (ip, ax, bx, f)

[estimate b as a zero of f]
a, b, c, d, e, fa, fb, fc, p, q, r, s, tol, l, xm, *outfile :=
f. 23-101 (a, b, c, d, e, f, fa, fb, fc, ip, p, q, r, s, tol, l, xm)

[set zeroin for return, zeroin := b]
zeroin := f. 103-103(b)
return

cnuf
Thus we have

**Lemma 5-11** The program function of \( f.5-11 \) is the constant function.

\[
((\emptyset, (\text{eps, tol } 1)) \mid (\exists \ k > 1 \ (\text{eps} = 2^{-k}) \ A \ 1 + 2 \ \text{eps} > 1 \ A \ \text{tol } 1 = 1 + \text{eps} < 1)
\]

Since \( \text{tol } 1 \) is reassigned (in PDL 36) before it is used again, \( f.5-11 \) can be thought of as computing only \( \text{eps} \).

**f.13-22** - The intermediate program which computes the value of \( f.13-22 \) is a sequence which can be written directly as a multiple assignment. It is convenient to retain the single output statement PDL 13, and write

\[
f.13-22 = f.13-13; f.14-22
\]

yielding

**Lemma 13-22** The \((a,b,c,d,e,*\text{outfile})\) projection of \( f.13-22 \) is function equivalent to the sequence

\[
f.13-13; f.14-22
\]

where \( f.13-13 = \text{if ip = i then write ('THE INTERVALS DETERMINED BY ZEROIN ARE')} \)

\[
f.14-22 = a,b,c,d,e := ax,bx,ax,bx-ax,bx-ax
\]

**f.23-101** - The intermediate program which computes the value of \( f.23-101 \) is a bit more complicated than the previous program segments and will be broken down into several subsegments. We begin by noticing that several of the input and output parameters may be eliminated from the list. Specifically, as noted earlier, \( p, q, r, \) and \( s \) are local variables to \( f.23-101 \) since they are always recalculated before they are used in \( f.23-101 \) and they are not used outside of \( f.23-101 \). The same is true for \( \text{xm} \) and \( \text{tol } 1 \). \( fa, fb, \) and \( fc \) can be eliminated since they are only used to hold the values of \( f(a), f(b) \) and \( f(c) \).

After considerable analysis and a number of false starts leading into a great deal of detail, we discovered an amazing simplification, first as a conjecture, then as a more precise hypothesis, and finally as a verified result. This simplification concerned the main body of the iteration of zeroin, namely
PDL 41-92, and obviated the need to know or check what kind of interpolation strategy was used, step by step. This discovery was that the new estimate of \( b \) always lay strictly within the interval bracketed by the previous \( b \) and \( c \).

That is, PDL 41-92, among other effects, has the \( (b) \) projection

\[
b := b + a(c - b), \text{ for some } a, 0 < a < 1
\]

so that the new \( b \) was a fraction \( a \) of the distance from the previous \( b \) to \( c \).

With a little more thought, it became clear that the precise values of \( d, e \) could be ignored, their effects being captured in the proper (but precisely unknown) value of \( a \). Furthermore, this new indeterminate (but bounded) variable \( a \) could be used to summarize the effect of \( d, e \) in the larger program part PDL 23-101, because \( d, e \) are never referred to subsequently. Thus, we may rewrite \( f.23-101 \) at this level as

\[
a, b, c \ast \text{outfile} := f.23-101 (a, b, c, f, ip)
\]

and we define it as an initialized while loop.

Lemma 23-101 The \((a, b, c, \ast \text{outfile})\) projection of \( f.23-101 \) is function equivalent to

\[
(ip = 1 \rightarrow \text{write} (b, c) \mid \text{true} \rightarrow I);
\]

\[
\left( \mid f(c) \mid < \mid f(b) \mid \rightarrow a, b, c := b, c, b \mid \text{true} \rightarrow I \right)
\]

while

\[
f(b) \neq 0 \wedge |(c-b)/2| > 2 \text{eps} \mid b \mid + tol/2
\]

do

\[
a, b, c := b, b + a(c-b), c \text{ where } 0 < a < 1;
\]

\[
(f(b) \neq f(c) > 0 \rightarrow a, b, c := a, b, a \mid \text{true} \rightarrow I);
\]

\[
(ip = 1 \rightarrow \text{write} (b, c) \mid \text{true} \rightarrow I);
\]

\[
\left( \mid f(c) \mid < \mid f(b) \mid \rightarrow a, b, c := b, c, b \mid \text{true} \rightarrow I \right)
\]

od

where \( I \) is the identity mapping.
The structure of $f_{23-101}$ corresponds directly to the structure of PDL 23-101 except for a duplication of segment PDL 23-34 in order to convert the dowhile do into a whiledo. The proof of the correctness of the assignments of $f_{23-101}$ is given in separate lemmas as noted in the comments attached to the functions in Lemma 23-101. The while test is obtained by direct substitution of values for tol 1 and xin defined in PDL 36-37 into the test in PDL 39 using eps as defined in Lemma 5-11.

**Lemma 24** PDL 24 is equivalent to $(i_p = 1 \rightarrow \text{write}(b, c) \mid \text{true} + 1)$

*pf:* By direct inspection

**Lemma 25-34** The $(a, b, c)$ projection of the program function of PDL 25-34 is function equivalent to

$$(|f(c)| < |f(b)| \rightarrow a, b, c := b, c \mid \text{true} + 1)$$

*pf:* By direct inspection of PDL 25-34

**Lemma 41-92** The $(a, b, c)$ projection of the program function of PDL 41-92 is function equivalent to

$$a, b, c := b, b + a(c-b), c \text{ where } 0 < a < 1$$

The proof will be done by examining the set of relationships that must hold among the variables in PDL 41-92 and analyzing the values of $p$ and $q$ only. That is, it is not necessary to have any knowledge of which interpolation was performed to be able to show that the new $b$ can be defined by

$$b := b + a(c-b) \ , \ 0 < a < 1$$

We will ignore the test on PDL 48 since it will be immaterial to the lemma whether linear or quadratic interpolation is performed. We will examine only the key tests and assignments and do the proof in two basic cases—interpolation and bisection—to show that the $(d)$ projection of the program function of PDL 41-78 is

$$d = (c-b) (a) \text{ where } 0 < a < 1$$
Case 1 Interpolation

If interpolation is done, an examination of Figure 6 shows that the following set of relations holds at PDL 78:

1. \( \text{tol} = 2 \cdot \text{eps} \cdot \text{abs}(b) + 0.5 \cdot \text{tol} \) (PDL 36)
2. \( \text{xm} = (c-b)/2 \) (PDL 37)
3. \( \text{abs}(\text{xm}) > \text{tol} 1 \) (PDL 39)
4. \( p > 0 \) (PDL 67)
5. \( 2 \cdot p < 3 \cdot \text{xm} \cdot q - \text{abs}([\text{tol} 1 \cdot q]) \) (PDL 70)
6. \( d = p / q \) (PDL 75)
7. \( \text{abs}(d) > \text{tol} 1 \) (PDL 83)

Now let's examine the set of cases on \( p \) and \( q \)

**p > 0 \& q < 0**

We have \( d = p / q < 0 \) (by hypotheses).

\[
\frac{p}{q} > 3 \cdot \frac{\text{xm} + \text{tol} 1}{2} \quad \text{(by I5), and tol 1 > 0 by(I1)}
\]

Since \( \text{abs}(\text{xm}) > \text{tol} 1 \) (by I3) and \( \frac{3 \cdot \text{xm} + \text{tol} 1}{2} < 0 \) (since \( p / q < 0 \))

we have \( \text{xm} < 0 \) implying \( 0 > d > \frac{p}{q} > 3 \cdot \frac{\text{xm}}{2} > 3 \cdot (c-b) > (c-b) \).

Thus \( 0 > d > (c-b) \) yielding \( d = \alpha(c-b) \) where \( 0 < \alpha < 1 \)

**p > 0 \& q > 0**

We have \( d = \frac{p}{q} > 0 \) (by hypotheses),

\[
\frac{p}{q} < 3 \cdot \frac{\text{xm} - \text{tol} 1}{2} < 3 \cdot \frac{\text{xm}}{2} = \frac{3}{4} (c-b) < (c-b) \quad \text{(by I5, I1, I2)}
\]

implying \( 0 < d < (c-b) \). Thus \( d = \alpha(c-b) \) where \( 0 < \alpha < 1 \)

**p > 0 \& q = 0**

\( q = 0 \) implies \( 0 > 2 \cdot p \) (by I5) and we know \( p > 0 \) (by hypotheses),

implying a contradiction
\( p = 0 \land q = \text{anything} \)

\[ \abs(p/q) > \text{tol} \quad \text{(by I6, I7)} \quad \text{and} \quad \text{tol} \geq 0 \quad \text{(by I1)} \quad \text{implies} \quad p \text{ cannot be} \quad 0 \]

\( p < 0 \land q = \text{anything} \)

\[ p > 0 \quad \text{(by I4)} \quad \text{implies a contradiction} \]

**Case 2 Bisection**

If bisection is done, an examination of Figure 6 shows that the following set of relations holds at PDL 78

- B1. \( x_m = (c-b)/2 \)  \quad \text{(PDL 37)}
- B2. \( \abs(x_m) > \text{tol} \)  \quad \text{(PDL 39)}
- B3. \( d = x_m \)  \quad \text{(PDL 45 or PDL 72)}

Here \( d = x_m \) (by B3) implies \( a = \frac{1}{2} \) (by B1) and thus \( d = (c-b)(a) \) where \( 0 < a < 1 \).

PDL 82-91 implies if \( |d| < \text{tol} \) (i.e., if \( d \) is too small) then increment \( b \) by \( \text{tol} \) with the sign adjusted appropriately.

i.e. set \( a = \begin{cases} d & \abs(d) > \text{tol} \\ \text{sign (tol, } x_m) & \text{otherwise} \end{cases} \)

But \( \text{tol} < \abs(x_m) \) (by I3 and B2) \( = \abs((c-b)/2) \) and the sign (tol) is set to the sign (xm) implying

\( \text{tol} = a(c-b) \) where \( 0 < a < 1 \)

Thus, in PDL 82-91 \( b \) is incremented by \( d \) or \( \text{tol} \), both of which are of the form \( a(c-b) \) where \( 0 < a < 1 \). Thus we have

\[ b := b + a(c-b) \quad , \quad 0 < a < 1 \]

and since in PDL 80-81 we have \( a, fa := b, fb \) we get the statement of the Lemma.
Once again, the reader is reminded that the proof of Lemma 41-92 was done by examining cases on p and q only. No knowledge of the actual interpolations was necessary. Only tests and key assignments were examined. Also, the program function was abstracted to only the key variables a, b, c and a represented the effect of all other significant variables.

**Lemma 93-100** The (a,b,c) projection of PDL 93-100 is function equivalent to

\[(f(b) \times f(c) > 0 \Rightarrow a, b, c := a, b, a | \text{true} + 1)\]

**pf:** By direct inspection, PDL 93-100 is an if then statement with if test equivalent to the condition shown above and assignments which include the assignments above.

The last function in zeroin 1 (from Figure 8) is the single statement PDL 103 which can be easily seen as

**Lemma 103** f.103 is function equivalent to zeroin := b

Now that each of the pieces of zeroin 1 have been defined, the program function of zeroin will be given. First, let us rewrite zeroin1, all in one place, using the appropriate functions (Figure 9).
func zeroinl (real ax, bx, f, tol, integer ip)
real a, b, c, d, e, eps, fa, fb, fc, a
file *outfile
[compute eps, the relative machine precision]
eps := (x | (k > 1 (x = 2^-k)) \& 1 + 2 x > 1 \& 1 + eps < 1); 
[initialize data]
(ip = 1 + *outfile := 'THE INTERVALS DETERMINED BY ZEROIN
ARE' | true + I) ;

a, b, c, d, e := ax, bx, ax, bx-ax, bx-ax
[estimate b as a zero of f]
(ip = 1 + *outfile (b, c) | true + I) ;
(abs(f(c)) < abs(f(b)) a, b, c := b, c, b | true + I)
while
f(b) \neq 0 \& (c-b)/2 > 2 eps \& b \neq tol/2
 do
 a, b, c := b, b + a (c-b), c where 0 < a < 1;*
 (f(b) * f(c) > 0 + a, b, c := a, b, a | true + I) ;
(ip = 1 + *outfile(b, c) | true + I) ;
(abs(f(c)) < abs(f(b)) + a, b, c := b, c, b | true + I)
 od
 [set zeroin for return, zeroin := b]
zeroin := b
return
cnuf

* a is an indeterminate based on the current values of a, b, c, d, e, f,
fa, fb, fc, tol and eps
Theorem 1-105

```plaintext
func zeroin has program function [zeroin] =
(ax = bx + root := bx |
 f(bx) = 0 + root := bx |
 f(ax) = 0 + root := ax |
 f(ax) * f(bx) < 0 + root := approx (f, ax, bx, tol) |
 true + (∀ k = 1,2,...,f(b_k) * f(c_k) > 0 + root := unpredictable |
 ∃ k > 0 (f(b_k) * f(c_k) ≤ 0 ∧ ∀ j = 1,2,...k -1, f(b_j) * f(c_j) > 0) +
 root := approx (f, b_k, c_k, tol)
```

where

approx (f, ax, bx, tol) is some value in the interval (ax, bx) within

4 * eps * |x| + tol of some zero x of the function f

and

the sequence (b1, c1), (b2, c2), ... is defined so that each

succeeding interval is a sub-interval of the preceding interval;

and in the case where abs(d)<tol 1 never occurs {bl, cl} = {ax, bx},

{b_{k+1}, c_{k+1}} defines the half interval of {b_k, c_k} including b_k, and

b_{k+1} is chosen to minimize abs(f(b_{k+1})).

Proof: The proof will be carried out in cases, corresponding to the conditions

in the rule given in the Theorem. The first three cases follow directly by

inspection of zeroin1, as special cases for input values, which

bypass the while loop. I.e., if ax = bx, then the values of a, b, c and

root can be traced in zeroin 1 as follows:

```
a  b  c  root
zeroin 1.8  bx  bx  bx
  .11  bx  bx  bx
[condition 13 fails since c-b = 0]
   .21  bx  bx  bx  bx
```
Cases 2 and 3 proceed in a similar fashion.

Case 4, \( f(ax) \cdot f(bx) < 0 \), will be handled by an analysis of the whiledo loop and its results will apply to the last subcase of the last case as well. The first subcase of the last case arises when no zero of \( f \) is even bracketed and zeroinl runs a predictable course, as will be shown.

**Case 4:** It will be shown that the entry condition \( f(ax) \cdot f(bx) < 0 \) leads to the following condition at the whiletest of zeroinl:

\[
I = (a = c \neq b \lor a < b < c \lor c < b < a) \land f(b) \cdot f(c) \leq 0 \land \text{abs}(f(b)) \leq \text{abs}(f(c))
\]

The proof is by induction. First I holds on entry to the whiledo loop because by direct calculation

- after zeroinl.8: \( a = c \land f(b) \cdot f(c) < 0 \land c \neq b \)
- after zeroinl.11: \( a = c \land f(b) \cdot f(c) < 0 \land \text{abs}(f(b)) \leq \text{abs}(f(c)) \land c \neq b \)

Next, suppose the invariant I holds at any iteration of the whiledo at the whiletest, and the whiletest evaluates true, it can be shown that I is preserved by the three-part sequence of the do part. In fact, it will appear that the first part, in seeking a better estimate of a zero of \( f \) may destroy this invariant, and the last two parts do no more than to restore the invariant.

It will be shown in Lemma 15-18 that:

- after zeroinl.15: \( a < b < c \lor c < b < a \land f(a) \cdot f(c) < 0 \)
- after zeroinl.16: \( a = c \neq b \lor a < b < c \lor c < b < a \land f(b) \cdot f(c) \leq 0 \)
- after zeroinl.18: \( a = c \neq b \lor a < b < c \lor c < b < a \land f(b) \cdot f(c) \leq 0 \land \text{abs}(f(b)) \leq \text{abs}(f(c)) \land \text{abs}(c-b) \leq \text{abs}(c_0 - b_0) \max (\alpha, 1-\alpha) \)

which is I, again. Thus, I is indeed an invariant at the whiletest.

Consider the question of termination of the whiledo. In Lemma 15-18T it will be shown using \( c_0 \) and \( b_0 \) as entry values to the do part, that for some \( \alpha, 0 < \alpha < 1 \), after zeroinl.18 \( \text{abs}(c-b) < \text{abs}(c_0 - b_0) \max (\alpha, 1-\alpha) \).
Therefore, the whiledo must finally terminate because the condition
\[ f(b) \neq 0 \land \text{abs}((c-b)/2) > 2 \ast \text{eps} \ast \text{abs}(b) + \text{tol}/2 \]
must finally fail, because by the finiteness of machine precision \( \text{abs}(c-b) \) will go to zero if not terminated sooner.

When the whiledo terminates, the invariant \( I \) must still hold. In particular \( f(b) \ast f(c) \leq 0 \), which combined with the negation of the whiletest gives
\[ \text{IT} = f(b) \ast f(c) \leq 0 \land f(0) = 0 \lor \text{abs}((c-b)/2) \leq 2 \ast \text{eps} \ast \text{abs}(b) + \text{tol}/2 \]
IT states that
1) a zero of \( f \) is bracketed by the interval \( (a, c) \)
2) either the zero is at \( b \) or the zero is at most \( |c-b| \) from \( b \),
i.e., the zero is within \( 4 \ast \text{eps} \ast |b| + \text{tol} \) of \( b \).

This is the definition of approx \((f, b, c, \text{tol})\).

Now, beginning with the interval \((ax, bx)\), every estimate of \( b \) created at zero1n.15 remains within the interval \((b,c)\) current at the time*. Since \( c \) and \( b \) are initialized as \( ax \) and \( bx \) at zero1n.8, the final estimate of \( b \) is given by approx \((f, ax, bx, tol)\). The assignment zero1n := b at zero1n.21 provides the value required by case 4.

Case 5: part 1. We first show that in this case the condition \( a = c \) will hold at zero1n.15 if \( f(b) \ast f(c) > 0 \). By the hypothesis of case 5, part 1, \( f((b+c)/2) \) is of the same sign as \( f(b) \) and \( f(c) \). Therefore, the first case of zero1n.16 will hold and the assignment \( c := a \) will be executed implying \( a = c \) when we arrive at zero1n.15 from within the loop. Also, if we reach zero1n.15 from outside the loop (zero1n.8-11) we also get \( a = c \).

We now apply Lemma 15L, which states that under the above condition the \((a, b, c)\) projection of zero1n.15 is

*this is because \( f(b) \ast f(c) \leq 0 \) is part of \( I \)
\[(f(b) * f(c) > 0 + a, b, c := b, \{b + (c-b)/2, b + tol 1\}, c)\]

if \(abs(c-b)/2 > tol 1\), otherwise

\[true + a, b, c := b, b + a(c-b), c\]

which is a refinement of zeroIt.15.

Note that zeroIt.18 may exchange b, c depending on \(abs(f(b))\) and \(abs(f(c))\).

Thus, the \((b, c)\) projection of the function computed by zeroIt.15-18 in this case is

\[b, c := \{b + (c-b)/2\}, b or b, c := b, \{b + (c-b)/2\}\]

i.e., the new interval \((b, c)\) is the half interval of the initial \((b_*, c_*)\) which includes \(b_*\) (for increments greater than tol 1), and the new b is chosen to minimize the value \(abs(f(b))\). The result of iterating this dopart is unpredictable unless more is known about the values of f. For example, if the values of f in \((a, b)\) are of one sign and monotone increasing or decreasing, the iteration will go to the end point \(a\) or \(b\) for which \(abs(f)\) is minimum. In general, the iteration will tend toward a minimum for \(abs(f)\), but due to the bisecting behavior, no guarantees are possible.

Case 5: part 2. This covers the happy accident of some intermediate pair \(b, c\) bracketing an odd number of zeroes of f by happening into values \(b_k, c_k\) such that \(f(b_k) * f(c_k) \leq 0\). The tendency to move towards a minimum for \(abs(f(b))\) may increase the chances for such a happening, but provide no guarantee. Once such a pair \(b_k, c_k\) is found, case 4 applies and some zero will be approximated.

This completes the proof of the theorem except for the proofs of the three lemmas used in the proofs which follow directly.
Lemma 15-18 The invariant I defined as

\[ I \equiv (a = c \neq b \lor a < b < c \land c < b < a) \land f(b) \ast f(c) \leq 0 \land \text{abs}(f(b)) \leq \text{abs}(f(c)) \]

is preserved by the execution of the loop body ZEROIN1.15-18.

Proof: We use the following abbreviations:

\[ P \equiv \text{abs}(f(b)) \neq 0 \land \text{abs}((c-b)/2) > 2 \ast \text{eps} \ast \text{abs}(b) + \text{tol}/2 \]

\[ I_0 \equiv ((c < b) \lor (c > b)) \land f(b) \ast f(c) < 0 \]

\[ I_1 \equiv (a < b < c \lor c < b < a) \land f(a) \ast f(c) < 0 \]

\[ I_2 \equiv (a = c \neq b \lor a < b < c \land c < b < a) \land f(b) \ast f(c) \leq 0. \]

Note that P is the loop predicate. The validity of the Lemma is an immediate consequence of the following conditions:

\[ C1 : I \land P \Longrightarrow I_0 \]

\[ C2 : I_0 \{\text{ZEROIN1.15}\} I_1 \]

\[ C3 : I_1 \{\text{ZEROIN1.16}\} I_2 \]

\[ C4 : I_2 \{\text{ZEROIN1.18}\} I \]

Condition C1 is straightforward. C2 can be seen by considering \( c < b \) and \( c > b \) as different input cases. Condition C3 follows from

\[ I_1 \land f(b) \ast f(c) > 0 \ (c := a) \ I_2 \ (\text{note that setting } c = a \text{ changes the sign of } f(c)) \]

\[ I_1 \land f(b) \ast f(c) \leq 0 \Longrightarrow I_2 \]

Similarly, C4 can be inferred from

\[ I_2 \land \text{abs}(f(c)) < \text{abs}(f(b)) \ (a, b, c := b, c, b) \ I \]

\[ I_2 \land \text{abs}(f(c)) \geq \text{abs}(f(b)) \Longrightarrow I. \]
Lemma 15-18T Given \( b, \ c \) on entry to zeroinl.15-18 then for some \( a, \ 0 < a < 1 \)

- after zeroinl.15 \( \text{abs}(c-b) = (1-a) \text{abs}(c_0-b_0) \)
- after zeroinl.16 \( \text{abs}(c-b) \leq \text{abs}(c_0-b_0) \max (a, 1-a) \)
- after zeroinl.18 \( \text{abs}(c-b) \leq \text{abs}(c_0-b_0) \max (a, 1-a) \)

**proof:** after zeroinl.15

\[
\begin{align*}
\text{abs}(c-b) &= \text{abs}(c_0-b_0 - a(c_0-b_0)) = \text{abs}(c_0-b_0)(1-a) \quad 0 < a < 1 \\
\text{abs}(b-a) &= \text{abs}(b_0+n(c_0-b_0) - b_0) = \text{abs} \alpha(c_0-b_0) \quad 0 < a < 1
\end{align*}
\]

after zeroinl.16

\[
\text{abs}(c-b) \leq \max \text{abs}(c_0-b_0)(1-a), \text{abs}(c_0-b_0)a
\]

\[
\leq \text{abs}(c_0-b_0) \max (a, 1-a)
\]

after zeroinl.18

\[
\text{abs}(c-b) \leq \text{abs}(c_0-b_0) \max (a, 1-a) \text{ since } b \text{ and } c \text{ are unchanged or exchanged.}
\]

It should be noted that in the above discussion, zeroinl.17 was ignored because its effect on the calculation of the root and termination of the loop is irrelevant.

We have one last lemma to prove.

**Lemma 15L** Given \( a = c \) and \( f(a) \neq f(b) > 0 \) then zeroinl.15 calculates the new \( b \) using the bisection method, i.e.,

\[
b := \begin{cases} 
  b + \frac{(b-c)}{2} & \text{if } \text{abs}(c-b) > \text{tol} 1 \\
  \text{tol} 1 & \text{otherwise}
\end{cases}
\]

**proof:**

From PDL 43, either \( \text{abs}(f(b)) < \text{abs}(f(a)) \) or bisection is done (PDL 45) with \( d = \text{xf} = (c-b)/2 \). Then PDL 82-91 implies

\[
b := \begin{cases} 
  b + d = b + \frac{(c-b)}{2} & \text{if } \text{abs}(c-b)/2 > \text{tol} 1 \\
  b + \text{tol} 1 & \text{otherwise}
\end{cases}
\]

Since by hypothesis \( a = c \), PDL 49 implies inverse quadratic
interpolation is not done and linear interpolation (PDL 56) is attempted. Thus
\[ s = \frac{f_b}{f_a} \text{ and } 0 < s < 1 \text{ since } f_b \neq f_a > 0 \text{ and } |f_b| < |f_a| \]
\[ p = (c-b) + s, \text{ using } x_m + (c-b)/2 \]
\[ q = 1-s, \text{ implying } q > 0 \text{ in PDL 59} \]
The proof will be done by cases on the relationship between \( b \) and \( c \).

\[ c > b \]
\( c > b \) implies \( p > 0 \) in PDL 58. Since \( p > 0 \) before PDL 62, PDL 65 sets \( q \) to \(-q\), so \( q < 0 \). Then the test at PDL 70 is true since
\[ 2 \times p = a \times s \text{ is positive,} \]
\[ 3.0 \times x_m \times q = \frac{1}{2} (c-b) \times q \text{ is negative, and} \]
\[ \text{abs(tol 1 \times q) is positive} \]
implying PDL 70 evaluates to true
and bisection is performed in PDL 72-73.

\[ c < b \]
\( c < b \) implies \( p < 0 \) in PDL 58. Since \( p < 0 \) before PDL 62, PDL 65 leaves \( q \) alone and PDL 67 sets \( p > 0 \) implying \( p = (b-c) \times x \).
Then the test at PDL 70 is true since
\[ 2 \times p = 2 \times (b-c) \times s \text{ is positive,} \]
\[ 3.0 \times x_m \times q = \frac{3}{2} (c-b) \times q \text{ is negative, and} \]
\[ \text{abs(tol 1 \times q) is positive} \]
implying PDL 70 evaluates to true
and bisection is performed in PDL 72-73.
IV. CONCLUSION

Answering the questions - We can now answer the questions originally posed by Professor Vandergraft.

Question 1:

If the equation is linear, the program will do a linear interpolation and find the root on one pass through the loop, except in the case where the size of the interval \((a, b)\) is smaller than \(\text{tol 1}\). Then it will do a bisection (from the test at PDL 43). Note the other potential condition where it may pass to PDL 44 for bisection is if \(\text{abs}(fa) - \text{abs}(fb)\) (from PDL 19, 26, and 43). However, in this case bisection is an exact solution. The case that the size of the interval is smaller than \(\text{tol 1}\) is unlikely, but can happen.

Question 2:

The theorem states that if \(f(a)\) and \(f(b)\) are both of the same sign, we will get an answer that is some point between \(a\) and \(b\) even though there is no root in the interval \((a, b)\) (case 5a of the Theorem). If there are an even number of roots in the interval \((a, b)\) then it is possible the program will happen upon one of the roots and return that root as an answer (case 5b of the Theorem). To check for this condition, we should put a test right at entry to the program between PDL 3 and PDL 4 of the form:

```plaintext
if 
    f(a) * f(b) > 0
then
    write ('F(A) and F(B) ARE BOTH OF THE SAME SIGN, RETURN B')
else
    PDL 4-102
fi
```
**Question 3:**

It would be easy to remove the inverse quadratic interpolation part of the code. We can do this simply by removing several PDL statements, i.e., PDL 47-55. However, this would not leave us with the best solution since much of the code surrounding the inverse quadratic interpolation could be better written. For example:

1. there would be no need to keep a, b, and c
2. the test in PDL 70 could be removed if we checked in the loop that \( f(a) \times f(b) \) was always greater than zero, since bisection and linear interpolation would never take us out of the interval.

Cleaning up the algorithm would probably require a substantial transformation.

**Question 4:**

Zeroin will find a triple root. It will not inform the user that it is a triple root, but will return it as a root because once it has a root surrounded by two points such that \( f(a) \) and \( f(b) \) are of opposite signs, it will find that root (case 4 of the Theorem).

**Program history** — Since most programs seen by practicing programmers do not have a history in the literature, we did not research the history of ZEROIN until we had completed our experiment. The complexity of the program is partially due to the fact that it was modified over a period of time by different authors, each modification making it more efficient, effective or robust. The code is based on the secant method (Ortega and Reindoldt). The idea of combining it with bisection had been suggested by several people. The first careful analysis seems to have been by T. J. Dekker (Dekkar). R. P. Brent (Brent) added to Dekker's algorithm the inverse quadratic interpolation option, and changed some of the convergence tests. The Brent book
contains an ALGOL 60 program. The FORTRAN program of Figure 1 is found in (Forsythe, Malcolm & Moler) and is a direct translation of Brent's algorithm, with the addition of a few lines that compute the machine-rounding error.

We understand that ZEROIN is a significant and actively used program for calculating the roots of a function in a specific interval to a given tolerance.

**Understanding and documenting** - As it turns out, we were able to answer the questions posed and discover the program function of ZEROIN. The techniques used included function specification, the discovery of loop invariants, case analysis, and the use of a bounded indeterminate auxiliary variable. The discovery process used by the authors was not as direct as it appears in the paper. There were several side trips which included proving the correctness of the inverse quadratic interpolation (an interesting result but not relevant to the final abstraction or the questions posed).

There are some implications that the algorithm of the program was over-designed to be correct and that the tests may be more limiting than necessary. This made the program easier to prove correct, however.

We believe this experience shows that the areas of program specification and program correctness have advanced enough to make them useful in understanding and documenting existing programs, an extremely important application today. In our case, we are convinced that without the focus of searching for a correctness proof relating the specification to the program, we would have learned a great deal, but would have been unable to record very much of what we learned for others.

Hamming pointed out that mathematicians and scientists stand on each other's shoulders, but programmers stand on each other's toes. We believe that will continue to be true until programmers deal with programs as mathematical objects, as unlikely as they may seem to be in real life, as we have tried to do here.
