This research was sponsored in part by the Army Research Office - Durham, Contract No. DAAG-29-78-G-0026, National Science Foundation Grants No. MCS-79-03145 and SOC-78-16811, and DOE Contract DE-AC03-76SF00326 PA#18.
1. Introduction and Abstract

By a cell we mean either a nonempty closed polyhedral convex set or a nonempty closed solid ball. Our concern is with solving as linear or convex quadratic programs special cases of the following two problems.

Optimal Containment Problem (OCP):

Let $\mathcal{X}$ be a finite union of cells and $\mathcal{Y}$ a finite intersection of cells. Find the smallest positive scale $s_\mathcal{Y}$ of $\mathcal{Y}$ for which some translate $s_\mathcal{Y} + t$ contains $\mathcal{X}$.

\[
\begin{align*}
\text{infimum: } & s \\
\text{OCP } \left\{ \begin{array}{l}
s, t \\
\text{subject to: } s_\mathcal{Y} + t \supseteq \mathcal{X}, \quad s > 0.
\end{array} \right.
\end{align*}
\]

Optimal Meet Problem (OMP):

Let $\mathcal{X}$ and $\mathcal{Y}_q$ for $q = 1, \ldots, p$, be each an intersection of cells. Find the smallest positive scale $s_{\mathcal{X}}$ of $\mathcal{X}$ for which some translate $s_{\mathcal{X}} + t$ meets every $\mathcal{Y}_q$ for $q = 1, \ldots, p$.

\[
\begin{align*}
\text{infimum: } & s \\
\text{OMP } \left\{ \begin{array}{l}
s, t \\
\text{subject to: } (s_{\mathcal{X}} + t) \cap \mathcal{Y}_q \neq \emptyset, \quad q = 1, \ldots, p \quad s > 0.
\end{array} \right.
\end{align*}
\]

The general OCP and OMP are well beyond our reach but serve as useful overviews. Depending upon the composition of the $\mathcal{X}$'s and $\mathcal{Y}$'s as unions and intersections of cells and the representation of the cells we can or cannot formulate the problems as linear or convex quadratic programs.
Our initial interest in OCP and OMP originated with "engineering
design" through interior solution concepts for convex sets, see van der
Vet [9] and Director and Hachtel [1]; also see Eaves and Freund [2].

2. Preliminaries

Most of the notation we use is standard. Let \( \mathbb{R}^n \) be \( n \)-dimensional Euclidean space. By \( \| \cdot \| \), we mean the Euclidean norm. \( x \cdot y \) and \( x \circ y \) represent inner and outer product, respectively. Let 
\( e = (1, 1, \ldots, 1) \) where its length is dictated by context. We define 
\( \inf \phi = +\infty \) as usual, but \( \sup \phi \leq 0 \) for the purposes of our presenta-
tion. By a convex program we mean a program of the form

\[
\begin{align*}
P \left\{ \begin{array}{l}
\text{minimum: } f(x) \\
\text{subject to: } g_i(x) \leq 0, \quad i = 1, \ldots, m,
\end{array} \right.
\end{align*}
\]

where all \( f, g_i \) are convex functions, and \( m \) is finite. If, in
addition, each \( g_i \) is affine, \( f(x) = xQx + q \cdot x \), and \( Q \) is
positive semi-definite, then we call \( P \) a quadratic program. Further-
more, if \( Q \) is zero, then we call \( P \) a linear program.

Let \( \mathcal{F} \) be a set in \( \mathbb{R}^n \). We denote by \( \text{tng}(\mathcal{F}) \) the smallest
vector subspace of \( \mathbb{R}^n \) for which some translate contains \( \mathcal{F} \). We
denote by \( \text{rec}(\mathcal{F}) \) the recession set of \( \mathcal{F} \), that is, the set

\[
\{ z \in \mathbb{R}^n \mid \exists x \in \mathcal{F} \text{ such that } x + \alpha z \in \mathcal{F} \text{ for any } \alpha \geq 0 \}.
\]

We also make use of the following variation of Farkas' Lemma.
Lemma: Suppose that the system of inequalities

\[ Ax \leq b \]

has a solution and that every solution satisfies \( cx \leq d \). Then there exists \( \lambda \geq 0 \) such that \( \lambda A = c \) and \( \lambda b \leq d \).

The manner in which cells are represented is crucial to our formulations. We assume all cells are in \( \mathbb{R}^n \). We define an H-cell to be a cell of the form

\[ \{ x \mid Ax \leq b \} \]

as it is represented by half-spaces; it is assumed \( (A,b) \) is given. A cell of the form

\[ \{ x \mid x = U\lambda + V\mu : e\lambda = 1, \lambda \geq 0, \mu \geq 0 \} \]

is defined to be a W-cell as it is a weighting of points; it is assumed \( (U,V) \) is given. Of course, every H-cell can be represented as a W-cell and vice versa. However, we shall suppose, and typically rightly so, that the computational burden of the conversion is prohibitive, see Mattheiss and Rubin [8] for H to W. Thus we shall regard H- and W-cells as quite distinct. A B-cell is defined to be the ball

\[ \{ x \mid \| c - x \| \leq r \} ; \]

it is assumed that the center \( c \) and radius \( r \geq 0 \) are given.
Let \( \mathcal{G} \) be a cell, and let \( s > 0 \) be a scale of \( \mathcal{G} \) and \( t \) a translate. If \( \mathcal{G} \) is an H-cell, \( \{x | Ax \leq b\} \), then
\[
s \mathcal{G} + t = \{x | Ax \leq bs + At\}.
\]
If \( \mathcal{G} \) is a B-cell, \( \{x | \|c - x\| \leq r\} \),
\[
s \mathcal{G} + t = \{x | \|(sc + t) - x\| \leq sr\}.
\]
And if \( \mathcal{G} \) is a W-cell,
\[
\{x | x = U\lambda + V\mu, e\lambda = 1, \lambda \geq 0, \mu \geq 0\}, \text{ then } s \mathcal{G} + t
\]
\[
= \{x | x = (sU + t \cdot e)\lambda + V\mu, e\lambda = 1, \lambda \geq 0, \mu \geq 0\} \text{ or equivalently}
\]
\[
s \mathcal{G} + t = \{x | x = t + U\lambda + V\mu, e\lambda = s, \lambda \geq 0, \mu \geq 0\}.
\]

To describe special cases of OCP and OMP we shall use notation as, for example, \((HB, WB, W)\) which denotes that \( \mathcal{G} \) is composed of any finite number of H-cells and one B-cell, and that \( \mathcal{G} \) or each \( \mathcal{G}_q \) are composed of any number of W-cells and B-cells but all B-cells have the same radius. If \( B \) is not subscripted by "=" or "1", then any finite number may be employed and the radii may vary. Thus, again, for example, \((HWB, HWB)\) describes the most general case of OMP or OCP.

Consider the following three programs

\[\begin{align*}
\text{Q1)} \quad \begin{cases} 
v_1 = \inf \text{imum: } s \\
\text{subject to: } \|w_i - (sc + t)\| + d \leq sr, \ i = 1, \ldots, m .
\end{cases}
\end{align*}\]

\[\begin{align*}
\text{Q2)} \quad \begin{cases} 
v_2 = \inf \text{imum: } f \\
\text{subject to: } \|w_i - x\|^2 \leq f, \ i = 1, \ldots, m .
\end{cases}
\end{align*}\]

\[\begin{align*}
\text{Q3)} \quad \begin{cases} 
v_3 = \inf \text{imum: } x - x - a \\
\text{subject to: } w_i \cdot w_i - 2w_i \cdot x + a \leq 0, \ i = 1, \ldots, m .
\end{cases}
\end{align*}\]
Assuming \( r \) is non-zero, we show that solving any one yields solutions to the other two. Let \( \sqrt{r} \) denote nonnegative square root.

**Equivalence of (Q1) and (Q2):** If \((s, t)\) and \((s, t)\) are feasible for (Q1) with \( \bar{s} < s \) (respectively: \( \bar{s} \leq s \)), then

\[
(f, x) = ((sr + d)^2, sc + \bar{t}) \quad \text{and} \quad (f, x) = ((sr + d)^2, sc + t)
\]

are feasible for (Q2) with \( \bar{f} < f \) (respectively: \( \bar{f} \leq f \)). If \((\bar{f}, \bar{x})\) and \((f, x)\) are feasible for (Q2) with \( \bar{f} < f \) (respectively: \( \bar{f} \leq f \)), then

\[
(s, t) = ((\sqrt{f + d})/r, \bar{x} - sc) \quad \text{and} \quad (s, t) = ((\sqrt{f + d})/r, x - sc)
\]

are feasible for (Q1) with \( \bar{s} < s \) (respectively: \( \bar{s} \leq s \)).

**Equivalence of (Q2) and (Q3):** If \((\bar{f}, \bar{x})\) and \((f, x)\) are feasible for (Q2) with \( \bar{f} < f \) (respectively: \( \bar{f} \leq f \)), then \((a, x)\) and \((a, x)\) are feasible for (Q3) with \( \bar{x} = f \)

\[
= f < x \cdot x - a = f
\]

(respectively: \( \bar{x} \cdot x - a = f \), \( \bar{x} \cdot x - a = \bar{x} \cdot x - a \)).

If \((\bar{a}, \bar{x})\) and \((a, x)\) are feasible for (Q3) with \( \bar{x} \cdot x - a < x \cdot x - a \)

(respectively: \( \bar{x} \cdot x - a < x \cdot x - a \)), then

\[
(\bar{f}, \bar{x}) = (\bar{x} \cdot x - a, \bar{x})
\]

and \((f, x) = (x \cdot x - a, x)\) are feasible for (Q2) with \( \bar{f} = \bar{x} \cdot x - a < f = x \cdot x - a \)

(respectively: \( \bar{f} = \bar{x} \cdot x - a < f = x \cdot x - a \)).

We thus have the following result.
Lemma 2.1 (Equivalence of (Q1) and (Q3)): For \( r \) non-zero

(i) If \((s,t)\) is feasible or optimal for (Q1), then \((a,x) = ((sc + t) \cdot (sc + t) - (sr - d)^2, sc + t)\) is feasible or optimal for (Q3), respectively.

(ii) If \((a,x)\) is feasible or optimal for (Q3), then \((s,t) = ((d + \sqrt{x \cdot x - a})/r, x - (d + \sqrt{x \cdot x - a})c/r)\) is feasible or optimal for (Q1), respectively.

Consequently (Q1) can be solved via the quadratic program (Q3). Note that (Q3), and hence (Q1), always has a unique optimal solution.

3. The Optimal Containment Problem (OCP)

Let \( \mathcal{R} \) be a finite union of cells and \( \mathcal{Y} \) be a finite intersection of cells. The optimal containment problem can be written as:

\[
\begin{align*}
\text{OCP1} & \quad \left\{ \begin{array}{l}
z_1 = \text{supremum:} \\
\quad s, t \\
\quad \text{subject to: } s\mathcal{R} + t \subseteq \mathcal{Y}, \ s > 0
\end{array} \right.
\end{align*}
\]

or as

\[
\begin{align*}
\text{OCP2} & \quad \left\{ \begin{array}{l}
z_2 = \text{infimum:} \\
\quad s, t \\
\quad \text{subject to: } \mathcal{R} \subseteq s\mathcal{Y} + t, \ s > 0
\end{array} \right.
\end{align*}
\]
Our first results concern the equivalence of OCPl and OCP2.

Lemma 3.1 (Equivalence of OCPl and OCP2):

(i) (Solutions) \((s,t)\) is a feasible or optimal solution to OCPl if and only if \((1/s, -t/s)\) is a feasible or optimal solution to OCP2.

(ii) (Feasibility) The following are equivalent:

\begin{itemize}
  \item [(a)] OCPl is feasible
  \item [(b)] OCP2 is feasible
  \item [(c)] \(\text{tng}(\mathcal{X}) \subseteq \text{tng}(\mathcal{Y})\) and \(\text{rec}(\mathcal{X}) \subseteq \text{rec}(\mathcal{Y})\).
\end{itemize}

(iii) (Attainment) The following are equivalent:

\begin{itemize}
  \item [(a)] \(0 < z_1 < +\infty\)
  \item [(b)] \(0 < z_2 < +\infty\)
  \item [(c)] OCPl has an optimum
  \item [(d)] OCP2 has an optimum.
\end{itemize}

(iv) (Non-attainment) The following are equivalent:

\begin{itemize}
  \item [(a)] \(z_1 = +\infty\)
  \item [(b)] \(z_2 = 0\)
  \item [(c)] \(\mathcal{X} + t \subseteq \text{rec}(\mathcal{Y})\) for some translate \(t\).
\end{itemize}

For a specific realization of OCPl or OCP2, \(\mathcal{X}\) and \(\mathcal{Y}\) will be given in the forms
\( \mathcal{X} = \bigcup_{h \in \mathcal{H}} H_h \cup \bigcup_{i \in \mathcal{B}} W_i \cup \bigcup_{j \in \mathcal{B}} B_j \) \\
\( \mathcal{Y} = \bigcap_{k \in \mathcal{K}} H_k \cap \bigcap_{l \in \mathcal{L}} W_l \cap \bigcap_{m \in \mathcal{M}} B_m \),

where \( H(.) = \{ x | A(.) x \leq b(.) \} \), \( W(.) = \{ x | x = U(.) \lambda + V(.) \mu \} \), \( \mathbf{e} \lambda = 1 \), \( \lambda \geq 0 \), \( \mu \geq 0 \), and \( B(.) = \{ x | ||c(.) - x|| \leq r(.) \} \). For a given set \( H(.) = \{ x | A(.) x \leq b(.) \} \), we define \( a(.) \) to be the column vector whose \( q \) th component is the (Euclidean) norm of the \( q \) th row of \( A(.) \).

We begin with case \( (HWB, H) \) of OCP which corresponds to \( \sigma = \phi \) and \( \tau = \phi \), that is, \( \mathcal{X} \) is a union of any finite number of \( H-, W-, \) and \( B- \) cells and \( \mathcal{Y} \) is an intersection of \( H- \) cells.

**Case \( (HWB, H) \) of OCP is a linear program**

We treat the optimal containment problem \( (HWB, H) \) through OCP2. The formulation as a linear program is

\[
\begin{align*}
\min_{s, t, A} & \quad z_2 = s \\
\text{subject to:} & \quad A_h A_h = A_k \\
& \quad A_h b_h - b_k s + A_k t \\
& \quad A_k U_i - b_k s + A_k t \\
& \quad A_k (V_1) \leq 0 \\
& \quad A_k c_j + a_k r_j - b_k s + A_k t \\
& \quad A_h b_h \geq 0 \\
& \quad s \geq 0.
\end{align*}
\]
Note that case $(B_1, H)$ of OCP, a special case of $(HWB, H)$, is the well-known problem of finding the largest ball inscribed in an $H$-cell, and has been part of the folklore of linear programming for over a decade.

**Case $(W, HW)$ of OCP is a linear program**

Formulated through OCP1, we have:

$$z_1 = \text{maximum: } s$$

subject to:

$$sU_i + t \in \mathbb{R} = U_k \eta_{ii} + V_k \pi_{ii}$$

$$V_i = V_k \omega_{ii}$$

$$A_k(sU_i + t \in \mathbb{R}) \leq b_k \in \mathbb{R}$$

$$A_k(V_i) \leq 0$$

$$\eta_{ii} \geq 0, \pi_{ii} \geq 0, \omega_{ii} \geq 0$$

$$s \geq 0.$$

**Case $(B_1, B_-)$ of OCP is a quadratic program**

Let $(c, r)$ be the given center and radius of the ball $\mathcal{A}$.

Treating the optimal containment problem through OCP1, we have:

$$z_1 = \text{maximum: } s$$

subject to:

$$\|c_m - (sc + t)\| + sr \leq r_n$$

$$s \geq 0.$$
If \( \mathcal{Y} \neq \emptyset \), i.e., the intersection of the \( B_m \) is not empty, then the constraint \( s \geq 0 \) is superfluous, and can be dropped. Since all \( r_n \) are equal, the above program is seen to be an instance of (Q1) and hence can be solved via the quadratic program (Q3). Note that if the optimal solution to the program (Q3) returns a negative value of \( s \), then \( \mathcal{Y} = \emptyset \). A variation of this problem was first shown to be a quadratic program by Gale [4].

Case \((B_m, B_1)\) of OCP is a quadratic program

Here we let \((c, r)\) be the given center and radius of the ball \( \mathcal{Y} \). Formulated through OCP2, the optimal containment problem is written as

\[
\begin{align*}
\min_{s,t} & \quad s \\
\text{subject to:} & \quad \|c_j - (sc + t)\|_r \leq sr \quad j \in \gamma \\
& \quad s \geq 0.
\end{align*}
\]

Note that the constraint \( s \geq 0 \) is superfluous, and can be omitted. As this program is a realization of (Q1), it is solvable as the quadratic program (Q3) for \( r > 0 \).

The special case of \((B_m, B_1)\) where all \( r_j = 0 \) is the problem of finding the smallest ball covering the points \( c_j, j \in \gamma \) and has been treated by Elzinga and Hearn [3] and Kuhn [7].
The case \((W, B_1)\) of OCP is a quadratic program

\((W, B_1)\) of OCP is a special case of \((B_n, B_1)\) just discussed when \(\text{rec}(\mathcal{X}) = \{\phi\}\) (else OCP is infeasible), since all \(V_1 = 0\) and each column of the \(U_1\) can be considered as the center of a B-cell with radius zero. Thus \((W, B_1)\) of OCP is solvable through the quadratic program \((Q3)\).

Other cases of OCP

Cases \((WB, HB)\) and \((W, HWB)\) of OCP can be formulated as convex programs using the logic already employed; however, we have been unable to formulate either case as a quadratic or linear program. As regards all other cases of OCP, we are convinced that their formulation as a convex program, much less a quadratic or linear program, cannot be accomplished. The reason for this is that the problem of testing \(\mathcal{X} \subseteq \mathcal{Y}\), where either (i) \(\mathcal{X}\) is an H-cell and \(\mathcal{Y}\) is a W-cell, (ii) \(\mathcal{X}\) is an H-cell and \(\mathcal{Y}\) is a B-cell, or (iii) \(\mathcal{X}\) is a B-cell and \(\mathcal{Y}\) is a W-cell, appears to be intractable without conversion of the polyhedra from H-cell to W-cell or vice versa.

4. The Optimal Meet Problem (OMP)

Let \(\mathcal{X}\) and \(\mathcal{Y}_q, q = 1, \ldots, p\), each be a finite intersection of cells. The optimal meet problem can be written as:

\[
\begin{aligned}
\text{OMP1} & \quad \text{subject to: } (s\mathcal{X} + t) \cap \mathcal{Y}_q \neq \emptyset & q = 1, \ldots, p, \\
& \quad s > 0
\end{aligned}
\]

or

\[
\begin{aligned}
\text{OMP1} & \quad \text{subject to: } s\mathcal{X} + t \cap \mathcal{Y}_q \neq \emptyset & q = 1, \ldots, p, \\
& \quad s > 0
\end{aligned}
\]
\[ v_2 = \sup_{s,t} s \]
\[ \text{subject to: } \mathcal{S} \cap (s \gamma_q + t) \neq \emptyset \text{ } q = 1, \ldots, p, \]
\[ s > 0. \]

The following result concern the equivalence of OMP1 and OMP2.

**Lemma 4.1 (Equivalence of OMP1 and OMP2):**

(i) (Solutions) \((s, t)\) is a feasible or optimal solution to OMP1 if and only if \((1/s, -t/s)\) is a feasible or optimal solution to OMP2.

(ii) (Feasibility) The following are equivalent:

(a) OMP1 is feasible
(b) OMP2 is feasible
(c) For some translate \(t\), \((t + \text{tng}(\mathcal{A}')) \cap \gamma_q \neq \emptyset, q = 1, \ldots, p.\)

(iii) (Attainment) The following are equivalent:

(a) \(0 < v_1 < \infty\)
(b) \(0 < v_2 < \infty\)
(c) OMP1 has an optimum
(d) OMP2 has an optimum.

(iv) (Non-attainment) The following are equivalent:

(a) \(v_1 = 0\)
(b) \(v_2 = +\infty\)
(c) For some translate \(t\), \((\text{rec}(\mathcal{A}) + t) \cap \gamma_q \neq \emptyset, q = 1, \ldots, p.\)
For a specific realization of OMP or OMP2, $\Omega$ and $\Omega_q$ will be given in the form:

$$\Omega = \bigcap_{h \in \Omega} H_h \cap \bigcap_{i \in \Sigma} W_i \cap \bigcap_{j \in \Gamma} B_j$$

$$\Omega_q = \bigcap_{k \in q} H_q \cap \bigcap_{l \in q} W_l \cap \bigcap_{m \in q} B_m \quad q = 1, \ldots, p,$$

where $H(\cdot), W(\cdot)$ and $B(\cdot)$ are as in section 3. Our solvable cases are as follows.

Case (HW, HW) of OMP is a linear program

Treated through OMP, case (HW, HW) is the linear program:

$$\nu_1 = \text{minimum} : s$$

$$\text{s, t, x, } \lambda, \mu$$

subject to: $A_h x < b_h, A_h t \quad h \in \Omega, q = 1, \ldots, p$

$A_k x_q < b_k q \quad k_q \in q, q = 1, \ldots, p$

$x_q = t + U_i \lambda_i q + V_i \mu_i q \quad i \in \beta, q = 1, \ldots, p$

$x_q = U_i \lambda_i q + V_i \mu_i q \quad i \in \sigma, q = 1, \ldots, p$

$e_i \lambda_i q = s, \lambda_i q \geq 0, \mu_i q \geq 0 \quad i \in \beta, q = 1, \ldots, p$

$e_i \lambda_i q = 1, \lambda_i q \geq 0, \mu_i q \geq 0 \quad i \in \sigma, q = 1, \ldots, p$

$s \geq 0.$
Case \((B_1, B_1m)\) of OMP is a quadratic program

This is the case where each \(\mathcal{A}_q\) is a ball of given center \(c_q\) and radius \(r_q\) with \(r_1 = \cdots = r_q > 0\). Let \(\mathcal{A}\) be the ball with center \(c\) and positive radius \(r\), and we proceed through OMPl. The formulation is

\[
\begin{align*}
 v_1 &= \text{minimum: } s \\
 s, t \\
 \text{subject to: } & \|c_q - (sc + t)\| \leq sr + r_q \\
 & q = 1, \ldots, p \\
 s & \geq 0.
\end{align*}
\]

If \(\bigcap_{q=1}^{p} \mathcal{A}_q = \emptyset\) (otherwise OMP does not attain its minimum), then the constraint \(s \geq 0\) is superfluous and can be omitted. Furthermore, since all \(r_q\) are equal, the above program is an instance of \((Q1)\) and hence can be solved via the quadratic program \((Q3)\).

Other cases of OMP

Note that the most general case of OMP, namely \((HWB, HWB)\), can be formulated as a convex program using the logic employed herein. However, we have been unable to formulate any case of OMP other than the above two cases as a quadratic or linear program.
5. Remark

Our final remark concerns the interrelated issues of computational complexity, the conversion of H- to W-cells and vice versa, and our division of problems solvable as quadratic or linear programs from other convex programs. In ([5] and [6]), it is shown that linear and (convex) quadratic programs are solvable in polynomial time. The conversion of an H- to W-cell, or vice versa, is an exponential problem.

To see this, consider the sets $\emptyset \triangleq \{ x \in \mathbb{R}^n \mid \| x \|_\infty \leq 1 \}$ and $\mathcal{D} \triangleq \{ x \in \mathbb{R}^n \mid \| x \|_1 \leq 1 \}$. $\emptyset$, as an H-cell, can be represented by $2^n$ halfspaces, but as a W-cell it requires the enumeration of at least $2^n$ (extreme) points. $\mathcal{D}$, as a W-cell, can be represented by $2^n$ (extreme) points, but as an H-cell it requires the enumeration of at least $2^n$ halfspaces. We thus see that our distinction of H-cells and W-cells as different entities is consistent from the standpoint of the solvability of the quadratic and linear programs contained herein.
