EXCITATION AND IONIZATION CROSS SECTIONS FOR ELECTRON BEAM AND MICROWAVE ENERGY DEPOSITION IN AIR

1. Introduction

The electron energy deposition in air, or any other gaseous element, requires a detailed consideration of all elastic and inelastic electron-atom and electron-molecule interactions. The inelastic processes include the excitation, dissociation and ionization of the air species. Electron excitation of molecules, however, are rotational, vibrational and electronic in nature. The elastic processes, on the other hand, constitute the electron neutral and the electron ion momentum transfer collisions.

Each collision process, by an electron with an air species, is characterized by a cross section. This cross section has to be known, experimentally or theoretically, over a wide energy range of the incident electron. The wide energy range, for the cross section, from excitation threshold to infinity, is required in order to account for the energy deposition of highly energetic electrons (the incident primary) and the generated secondaries and tertiaries, down to the thermal electrons. However, the low energy behaviour of the cross section from threshold to few times beyond threshold is also essential for the microwave energy deposition in air.

In this report we present a set of cross sections for the electron collisions with N₂, O₂, O and N. Data on these cross sections were reported previously. However, some have changed drastically, while new data have become available where none existed before. Furthermore, disagreement exists on the shape and the peak value of the cross section when there is more than one source for the data, as can be seen in this report.

2. Nitrogen Molecule

2.1 Vibrational Excitation Cross Section

The electron impact excitation cross section for eight ground state vibrational levels of the nitrogen molecule have been measured by

Manuscript submitted June 29, 1981.
Schulz and Ehrhardt and Willman. Theoretical calculations have been carried out with satisfactory reproduction of the experimental results. The measured cross sections of Schulz are shown in Figures 1 - 8 for the individual vibrational levels adjusted to a peak value of $6.0 \times 10^{-16}$ cm$^2$ at 2.5 eV for the total vibrational excitation cross section, which is in good agreement with a previously predicted value.

2.2 \textit{N}_2-Triplet States

\textit{A}^3\Sigma: The electron impact excitation cross section of \textit{A}^3\Sigma state from the ground state of \textit{N}_2, has been calculated and measured by several investigators. These results are shown in Fig. 9 except for Cartwright's earlier calculation which is larger by a factor of \textasciitilde1.6 compared to the calculations of Chung and Lin. The most recent measurement by Cartwright, et al., however, has the lowest value for the peak cross section compared to other measurements. Furthermore, the peak of the cross section occurs at an electron energy of \textasciitilde17 eV compared to \textasciitilde11 eV for measurements of Brinkman and Trajmar and Borst. The theoretical calculation of Chung and Lin also predict the peak cross section to occur at 11 eV.

The best choice for the cross section, in our view, is that of Borst, provided the peak of the cross section is adjusted to the recent value of Cartwright, et al. to eliminate the effect of cascade contribution from higher levels. The lowest electron energy, for which cross section data is available, is 8 eV. The extension of the cross section downward to the threshold, which is at 6.17 eV, is indicated by a dashed line (See Fig. 9). For electron energies above 40 eV, the cross section data can be obtained using the $\frac{1}{E^3}$ dependence of the cross section on the electron energy.
B$^3\Pi$: The electron impact excitation of the B$^3\Pi$ state from the ground state of N$_2$, has been measured by Cartwright, et al\textsuperscript{13} and Brinckman and Trajmar\textsuperscript{11} and calculated by Cartwright\textsuperscript{9} and Chung and Lin\textsuperscript{10}.

As seen from Figure 10, there is good agreement between the theoretical\textsuperscript{10} and the recently measured\textsuperscript{13} cross section except for their behaviour at electron energies above 30 eV. The theoretical cross section of Cartwright\textsuperscript{9} is not shown in Figure 10. However, its peak value is $\sim 3.1 \times 10^{-17}$ cm$^2$ and occurs at $\sim 17$ eV.

For electron energies above 30 eV the cross section data can be obtained using the $\frac{1}{E^2}$ dependence\textsuperscript{14,15} of the cross section on the electron energy. At the low energy, data is available at 8 eV. This could be extended downward to zero at threshold, which is at 7.4 eV.

C$^3\Pi$: The electron impact cross section for the excitation of the C$^3\Pi$ state, from the ground state of N$_2$, has been measured\textsuperscript{11,13} and calculated.\textsuperscript{9,10} There is good agreement between the theoretical values\textsuperscript{9,10} as well as the experimental\textsuperscript{11,15} data as seen in Fig. 11. The theoretical cross section of Cartwright\textsuperscript{9} is not shown. However, its peak value is $\sim 4.4 \times 10^{-17}$ cm$^2$ and occurs at $\sim 15$ eV.

The high energy behaviour of the cross section can be obtained by utilizing the energy dependence of the (0,0) emission at 3371Å, also shown in Fig. 11, as measured by Imami and Borst\textsuperscript{16}. The energy dependence of the cross section follows an $E^{-2.2}$ rather than the expected $E^{-3.0}$ dependence. The absolute cross section for the (0,0) emission can be converted into an absolute cross section for the total excitation of C$^3\Pi$ state by multiplying the emission cross section by a factor of 3.55, where the appropriate Franck Condon factors are utilized. This brings the peak cross section to $3.9 \times 10^{-17}$ cm$^2$ which is in good agreement with measurements of Cartwright, et al\textsuperscript{13} and Brinckman and Trajman\textsuperscript{11}. The best choice would be
the latest measured cross section with the utilization of the $E^{-2.2}$ dependence for the cross section above 50 eV. For low energy, the data at 12 eV can be extended downward to zero at threshold, which is at 11.0 eV.

\[W^3\Delta: \text{The electron impact excitation cross section of } W^3\Delta \text{ state from the ground state of } N_2 \text{ has been measured and calculated. However, the experimental value is higher by a factor of 5 compared to the calculated value at the peak. Furthermore, the shape of the theoretical cross section differs variedly from the measured shape. We opt for the experimental data which has an expected shape for a singlet to triplet excitation. The high energy value should follow a } E^{-3.0} \text{ dependence. The low energy portion can be obtained by extending the value at 8 eV downward to zero at threshold, which is at 7.36 eV.}\]

\[B^3E: \text{The electron impact excitation cross section of } B^3E \text{ from the ground state of } N_2 \text{ has been measured by Cartwright et al. No other data is available. The high energy behaviour can be scaled with an } E^{-3.0} \text{ dependence. For the low energy portion, data is available at 9 eV and can be scaled downward to zero at threshold, which is at 8.2 eV.}\]

\[E^3\Sigma: \text{The electron impact excitation cross section of } E^3\Sigma \text{ state from the ground state of } N_2 \text{ has been calculated and measured. However, the agreement is not good. The theoretical cross sections of Cartwright and Chung and Lin yield peak values of } 1.7 \times 10^{-17} \text{ cm}^2, 3.7 \times 10^{-18} \text{ cm}^2, \text{ respectively. The recent measurement, on the other hand, has a peak value of } \sim 0.80 \times 10^{-18} \text{ cm}^2 \text{ and is shown in Fig. 14. The excitation threshold for the } E^3\Sigma \text{ is 11.9 eV.}\]

2.3 $N_2$ Singlet States

\[a^1\Sigma: \text{The electronic impact excitation cross section of } a^1\Sigma \text{ state from the ground state of } N_2 \text{ has recently been measured and is shown in}\]
Fig. 15. The high energy behaviour can be scaled from the present data with a $\frac{1}{E}$ dependence.

\(a^1\Pi\): The electron impact excitation of the \(a^1\Pi\) state from the ground state of \(N_2\) has been calculated\(^{10}\) and measured\(^{11,12,13,19,20}\) extensively. There seems to be a reasonable agreement on the shape of the measured cross sections. Measurements of Borst\(^{12}\) and Fin and Doering\(^{19}\) are in excellent agreement. They are higher by \(\sim 25\%\) compared to the recent measurement of Cartwright, et al.\(^{13}\) These cross sections are shown in Fig. 16 for comparison. Ajell's\(^{20}\) cross section is not shown; however, it is in good agreement with that of Finn and Doering\(^{19}\) from threshold to an electron energy of \(\sim 20\text{ eV}\). Beyond 20 eV, however, it falls off slower with energy compared to that of Finn and Doering\(^{19}\). The latest measurement\(^{13}\) is preferred for modeling purposes and data above 50 eV is to obtained by scaling the cross section with a \(E^{-1}\) dependence. On the other hand, for lower energy the cross section can be obtained by scaling data at the lowest energy to zero at threshold, which is at 8.5 eV.

\(\omega^1\Delta\): The electron impact excitation cross section of \(\omega^1\Delta\) state from the ground state of \(N_2\) has been calculated\(^{13}\) and measured\(^{13}\). The agreement between the calculated and the measured cross section is very poor. The recent measured\(^{13}\) value, however, as shown in Fig. 17 is preferred. The high energy behaviour should follow an \(E^{-1}\) dependence. The energy data can be estimated by scaling the data at the lowest energy to zero at threshold, which is at 8.9 eV.

\(a^*^1\Sigma\): The electron impact excitation cross section of \(a^*^1\Sigma\) state has been measured\(^{13}\) and calculated\(^{10}\). However, the agreement is very poor in the shape, where the peak occurs, and the high energy behaviour. The experimental\(^{13}\) cross section should be preferred. For high energy the \(\sigma\) is to be scaled with \(E^{-1}\) dependence. For low energy, the data at the lowest
energy is to be scaled downward to zero at threshold, which is at 12.3 eV.

2.4 Higher level singlets and triplets

Higher lying singlet and triplet cross sections in the electron energy range of 12.5 - 14.2 have beam measured by Chutjian, et al\cite{21}, however, most of the singlet states contribute to the dissociation of N\textsubscript{2} through their predissociation (See Section 2.5) and will not be given here. However the cross sections for two triplet states, F\textsuperscript{3}T\textsubscript{r} and G\textsuperscript{3}T\textsubscript{r} and two triplet-like states, designated M\textsubscript{1} and M\textsubscript{2} by Chutjian et al\cite{21}, are shown in Fig. 19.

2.5 The Dissociation Cross Section of N\textsubscript{2}

The total dissociation cross section of N\textsubscript{2} by electron impact was first measured by Winter\cite{22} for electron energies up to 300 eV. This total cross section is the sum of two distinct processes which have different threshold energies. These processes are the pure dissociation of N\textsubscript{2} where the atoms are either in their ground state or in an excited state (Dissociative Excitation), and the dissociative ionization. The dissociative ionization can result in the products of the dissociation to be either in their ground states or in an excited state. The simple dissociation of N\textsubscript{2} can be obtained from the total dissociation cross section by subtracting the contribution of the dissociative ionization.

Recently, Zipf and McLaughlin\cite{23} have analysed the electron impact dissociation in considerable detail, delineating the contribution of various excited states towards the total dissociation of N\textsubscript{2}. The total dissociation cross section analysed in this manner is in good agreement with measured cross sections of Winters\cite{22} and Niehaus\cite{23}.

In the analysis of Zipf and McLaughlin\cite{23}, it is shown that the N\textsubscript{2} singlet states in the energy range of 12.5 to 14.9 eV account for 60% of the total dissociation cross section, through their predissociations. Therefore, it is not necessary to provide additional individual cross
sections for $N_2$ singlets, e.g. $b'\Sigma$, $\pi_u$, etc. Data is available on this if desired.

The total cross section for the dissociation of $N_2$ is shown in Figure 20. Also shown in this figure are the electron impact dissociative excitations which result in vacuum ultraviolet emissions from the nitrogen atom. Data from various references$^{25-28}$ are utilized to construct these emission cross sections.

2.6 Ionization and Dissociative Ionization Cross Sections of $N_2$

The total electron impact ionization cross section for $N_2$ has been measured by Rapp and Golden$^{29}$ and Tate and Smith$^{30}$ for electron energies from threshold to 1000 eV. The dissociative ionization has also been measured in the same electron energy range. The data for ionization$^{29}$ and dissociative ionization$^{31}$ are shown in Figure 21. A recent measurement$^{32}$ of the dissociative ionization cross section for electron energies of 30 - 60 eV is also shown in Fig. 21 where at 60 eV the new data is $\sim 50\%$ higher than that of Rapp et al.$^{31}$

The ionization cross section measurements have been extended to an electron energy of 20,000 eV by Schram, et al.$^{33}$ This data overlaps with measurements of Rapp and Englander-Golden$^{28}$ in the energy range of 600-1000 eV and is lower by $\sim 20\%$. A measurement$^{34}$ for the ionization cross section exists at an electron energy of 1.5 MeV. The extension of Rapp and Englander-Golden data to higher energies is shown in Figure 22 where data from Schram, et al.$^{33}$ normalized to Rapp and Englander-Golden$^{29}$, is utilized. For still higher energies one must consider relativistic and polarization effects where the cross section becomes almost constant.

The partial ionization cross sections leading to various ionization continua of $N_2$ i.e., X, A, B states of $N_2^+$ are also shown in Fig. 21.
Data at 21 eV and 100 eV are utilized\textsuperscript{32,35,36} to construct these cross sections. At 21 eV, the distribution\textsuperscript{32} of the X, A and B states are 0.36, 0.56 and 0.08 of the total ionization cross section, respectively. At 100 eV, the absolute emission cross section\textsuperscript{35} of the (0,0) band of the first negative system and the total\textsuperscript{36} cross section of the A-state are utilized with the total and dissociative ionization cross sections to obtain the partial ionization cross section.

For higher electron energies the percent contributions of the various states at 100 eV is utilized. These cross sections and the pure dissociation cross section of N\textsubscript{2} are also shown in Fig. 22.

3. Oxygen Molecule

3.1 Vibrational Excitation Cross Section O\textsubscript{2}

The electron impact excitation of O\textsubscript{2} was measured by Spence and Schulz\textsuperscript{37}. However, the measurements indicated that the cross sections were small with peak values of \( \sim 10^{-19} \) cm\(^2\) for the excitation of \( V=1 \) and \( V=2 \) states. Linder and Schmidt\textsuperscript{38}, however, have obtained cross sections for the same levels which are larger by approximately two orders of magnitude. The individual cross sections are very narrow and are shown in Fig. 23.

3.2 \( a^1\Delta \) and \( b^1\Sigma \) States of \( \text{O}_2 \)

The electron impact excitation cross sections of \( a^1\Delta \) and \( b^1\Sigma \) states of O\textsubscript{2} (forbidden transitions) have been measured for electron energy in the range of 2-4 eV by Lindner and Schmidt\textsuperscript{38} and in the range of 5-50 eV by Trajanov, et al.\textsuperscript{39,40} and from 20 - 200 eV by Wakiya\textsuperscript{41}, Julienne and Krauss\textsuperscript{42} have calculated the electron impact excitation cross section for \( a^1\Delta \) using Born approximation. However, the agreement between theory and experiment near threshold is poor, as would be expected. On the other hand, the agreement is very good in the energy range of 20 - 50 eV. Cross
sections for $a^1\Delta$ and $b^1\Sigma$ based on measured values is presented in Fig. 24. For higher energies the cross sections can be scaled with energy dependence $E^{-2.7}$ and $E^{-2.9}$ for $a^1\Delta$ and $b^1\Sigma$, respectively.

### 3.3 $A^3\Sigma^+$

The electron impact excitation of three electronic states, $A^3\Sigma^+$, $C^3\Delta$, and $C^1\Sigma^+$ (Forbidden Transitions), from the ground state of $O_2$, have been measured by Wakiya $^{41}$ for electron energy range of 20-500 eV and by Trajmar, et al. $^{40}$ at 20 and 40 eV. Wakiya's data are presented in Fig. 25. The cross section below 20 eV, shown as a dashed line in Fig. 25, is obtained using the theoretical expression given by Green and Stolarski, normalized to experimental data at 20 eV. For electron energies above 300 eV the cross section can be scaled with an energy dependence $E^{-1}$. The excitation cross section for $A^3\Sigma^+$ is to be utilized as a dissociation cross section resulting in two oxygen atoms in their ground state.

### 3.4 $B^3\Sigma^-$

The electron impact excitation cross section of the $B^3\Sigma^-$ state from the ground state of $O_2$ has been measured by Wakiya $^{44}$ and calculated by Lin and Chung. $^{45}$ The experimental and theoretical cross sections are shown in Fig. 26. For electron energy below 20, where no experimental data is available, the shape of the theoretical cross section is used as a guide. At higher energies the cross section can be scaled with an $E^{-1}$ dependence.

The excitation cross section for the $B^3\Sigma^-$ state is to be utilized as a dissociation cross section resulting in $O$ and $O(1D)$.

### 3.5 The Ionization and Dissociative Ionization of $O_2$

The total electron impact ionization cross section of $O_2$ has been measured by Tate and Smith $^{30}$ and Rapp and Englander-Golden $^{29}$ for electron energies up to 1000 eV. Hirsh, et al. $^{34}$, have measured the ion-
zation cross section at an electron energy of 1.5 MeV. The ionization cross section \(^\text{29}\) is shown in Figure 27 and its extension to energies higher than 1000 eV can be made following the scaling law of \(\sigma \sim E^{-1} \log CE\).

The dissociative ionization cross section is shown in Fig. 27 based on the measurement of Rapp, et al.\(^{31}\)

The partial ionization cross sections leading to various ionization continua of \(\text{O}_2\) are also given in Figure 27. These cross sections are based on data at 100 eV for the \(b^4 \Sigma\) state measured by McConkey and Woolsey.\(^{46}\) The measurements of Skubenich\(^{47}\) for the cross sections of \(b^4 \Sigma\) and \(A^2 \pi\) states are utilized for the relative ratio between these two states. This ratio is used to obtain the cross section for the \(A^2 \pi\) state, by utilizing McConkey and Woolsey data for \(b^4 \Sigma\) state. Subtracting the cross section values of \(b^4 \Sigma\), \(A^2 \pi\) and the dissociative ionization from the total ionization cross section one obtains the sum for the excitation of the \(X^2 \pi\) and \(a^4 \pi\) states. This sum then is divided between \(X^2 \pi\) and \(a^4 \pi\) states according to their statistical weights.

4. Oxygen Atom

4.1 Oxygen Atom Low Lying Metastable States \(O^1(\text{D})\) and \(O^1(\text{S})\)

The electron impact excitation cross sections for the low lying metastable states of oxygen atom have been calculated by numerous investigators.\(^{48-50}\) There seems to be good agreement between these calculations, especially for the excitations of \(^1\text{S}\) state. For the excitation of \(O^1(\text{D})\), however, the difference in the slope of the cross sections at threshold and near threshold is apparent. The calculated cross section by Thomas and Nisbet\(^{49}\) is preferred. No experimental data are available on these cross sections.

4.2 Optically Allowed Transitions

For optically allowed transitions, the following expression,
given by Drawin, will be utilized.

\[ \sigma = 3.5 \times 10^{-16} f_{ij} \left( \frac{13.6}{E_{ij}} \right)^2 \left( \frac{E_{ij}}{E} \right)^2 \left( \frac{E}{E_{ij}} - 1 \right) \log \left( \frac{1.25 E}{E_{ij}} \right) \]

Here, \( f_{ij} \) is the oscillator strength for the transition \( i \rightarrow j \) whose excitation energy is \( E_{ij} \) and \( E \) is the electron energy. Using this expression, the electron impact excitation cross sections for few optically allowed transitions are given in Figure 29. The above expression used for the transition \( ^3P \rightarrow ^3S \) (the resonance line) yield a peak value which is lower by a factor of \( \sim 2 \) compared to a measurement by Stone and Zopf.

4.3 Ionization Cross Section of O

The electron impact ionization cross section of oxygen atom has been measured by Fite and Brackmann and is shown in Figure 30. The decomposition of the total ionization cross section into various ionization continua of \( O^+ \), i.e. \( O^+(^4S) \), \( O^+(^2D) \) and \( O^+(^2P) \) can be made using Table 1. The percentage of the fractional ionization cross sections are given as a function of the electron energy. Data for Table 1 for electron energy up to 100 eV is from Dalgarno and Lejeune.

5. Nitrogen Atom

5.1 Low lying Metastable States $N(^2\text{D})$ and $N(^2\text{P})$

The electron impact excitation cross sections for the low lying metastable states, $N(^2\text{D})$ and $N(^2\text{P})$, have been calculated by several investigators.\textsuperscript{48,55,56} These calculated cross sections are shown in Figures 31-33. The calculations of Berrington, et al.\textsuperscript{55} is to be preferred because they include the effects of target polarization, higher lying configurations and short range correlations.

5.2 Optically Allowed Transitions

For optically allowed transitions one can utilize the cross section expression given in Section 4.2 of this report. Using this expression the excitation cross sections for two optically allowed states are illustrated in Figure 34. For the rest of the optically allowed states one generally needs the excitation energies and the oscillator strengths which can be found in Ref. 57.

5.3 Ionization Cross Section of Nitrogen Atoms

The electron impact ionization cross section of nitrogen atom has been measured\textsuperscript{58} and is shown in Figure 35.

Fig. 19 — The cross section for the electron impact excitation of $N_2(F^3\Pi_u)$, $N_2(G^3\Pi_u)$ and $M_1$ states indicated as 1, 2 and 3, respectively. Data are from reference 21.
Fig. 20 — Cross sections for the electron impact dissociative excitation emission at 1134 Å, 1200 Å, 1243 Å, 1493 Å and 1743 Å shown as curves 1, 2, 3, 4 and 5, respectively. (See text for references.) The N\textsubscript{2} dissociation cross section is shown as curves 6 (ref. 22) and 7a and 7b (ref. 23), where a and b indicate optically thick and thin cases.
Fig. 21 — The N₂ ionization cross section is shown as curve 1 (ref. 29). The N₂ dissociative ionization is shown as curves 2 (ref. 31) and 3 (ref. 32). The peak cross sections for ionization leading to N₂⁺(A), N₂⁺(B) and for emission at 3914 Å are indicated □A, ○B and ○B, respectively.
Fig. 22 — The electron impact ionization and dissociative ionization of $N_2$ are designated as curves 1 and 2, respectively. Curves 3, 4 and 5 are the partial ionization cross sections leading to $N_2^+(X)$, $N_2^+(A)$ and $N_2^+(B)$ states. Curve 6 indicates the pure dissociative cross section of $N_2$. 
The electron impact excitation cross section for the ground state vibrational level of O₂ (ref. 38)

Fig. 23
Fig. 24 – The electron impact excitation cross section of $O_2(a^1\Delta)$ and $b^1\Sigma$. (See text for references.)
Fig. 25 — The electron impact excitation cross section for $\text{O}_2$ states of $\Lambda^3\Sigma + \Sigma^3\Delta + \Sigma^1\Sigma$
Fig. 26 — Cross section for the electron impact excitation of $O_2(B^3\Sigma)$. Curve 1 (ref. 15), curve 2 (ref. 44). Also see text.
Fig. 27 — Cross section for the electron impact ionization and dissociative ionization of O₂ indicated as curves 1 (ref. 29) and 2 (ref. 31), respectively. The partial ionization cross section leading to b¹π, A²π, a⁴π and x²π states are designated as curves 3, 4, 5 and 6, respectively. (See text for detail.)
Fig. 28 — Electron impact excitation cross sections for low lying metastable states of oxygen atom, solid curve (ref. 49), dashed curve (ref. 50) and circles (ref. 48)
Fig. 29 — Electron impact excitation cross section for the optically allowed transitions in O. Curves 1, 2, 3 and 4 are for transition from 3P to 3S, 3D0, 3P0 and 3D0 where excitation energies are 9.48, 12.48, 14.06 and 12.03 eV, respectively.
Fig. 30 — The electron impact ionization cross section of oxygen atom (ref. 53)

Fig. 31 — The electron impact excitation cross section for $N(^2D)$. Solid curve (ref. 55), dashed curve (ref. 48) and circles (ref. 56).
Fig. 32 — The electron impact excitation cross section of \textit{N}^2P). Solid curve (ref. 55), dashed curve (ref. 48) and circles (ref. 56).

Fig. 33 — The electron impact excitation cross section for the \textit{2D}^2P transition in nitrogen. Solid curve (ref. 55), dashed curve (ref. 48) and circles (ref. 56).
Fig. 34 — The electron impact excitation cross section for two optically allowed transitions in nitrogen, curve 1 for transitions $^4S_0 - ^4P$ and $^4S_0 - ^4P$, where excitation energies are 10.87 and 10.28 eV, respectively.
Fig. 35 — The electron impact ionization cross section for nitrogen atom (ref. 58)
