<td>This report is a tutorial for learning graphics programming with the Graphics Compatibility System (GCS). GCS is a collection of ANSI standard FORTRAN subroutines invocable by a user's FORTRAN program. The report covers GCS's capabilities. GCS can produce a simple line drawing or handle comprehensive general purpose axis creation and automatic clipped arc and conic generation; graphics input; secondary coordinate systems; multiple software character fonts; data structures; segmentation; and color. The report addresses both two- and three-dimensional graphics capability within GCS.</td>

This report is the result of work performed under Contract No. DACW39-78-M-2676, dated 3 April 1978, between the U. S. Army Engineer Waterways Experiment Station (WES), Vicksburg, Miss., and the Westinghouse Word Processing Center, Pittsburgh, Pa. The work concerned publishing a word processing version of the Primer on Computer Graphics Programming. The original version of this primer was developed at the U. S. Military Academy.

Contributors to the document were Dr. Richard Puk, Sandia Laboratories; Dr. Steve Orbon and Mr. Robert Bruns, Westinghouse; and Mr. James M. Jones II, R&D Software Group, Automatic Data Processing (ADP) Center, WES. The work was administered by the ADP Center, WES, as part of Computer Technology-Engineering Software, Project No. 4A762725AT11, and the Civil Works Computation and Analysis Project sponsored by the Office, Chief of Engineers, U. S. Army (OCE). OCE points of contact were Mr. Robert McMurrer (DAEN-DSE) and Messrs. Richard Malm and Harry Hardin (DAEN-CWE-BA).

Mr. Jones monitored the contract under the general supervision of Dr. N. Radhakrishnan, Special Technical Assistant to the Chief of the ADP Center, WES, and Mr. D. L. Neumann, Chief of the ADP Center.

Directors of WES during the period of the contract and the preparation of this report were COL J. L. Cannon, CE, and COL N. P. Conover, CE. Technical Director was Mr. F. R. Brown.

</table>
INTRODUCTION

THE GCS RESEARCH AND DEVELOPMENT PROJECT

The traditional forms of computer output — vast piles of densely printed computer listings — often leave managers, engineers and students confused and frustrated. Often the information one wants to know is somewhere in the computer output, but not in a form wherein the user can find what he wants, understands, or can easily assimilate.

For years the computer field has looked forward to breaking this bottleneck in computer-human communications by using pictures instead of printouts. The idea is not new. The first stored-program, electronic computer ever designed had in its initial design an oscilloscope which was supposed to give graphic displays of the solutions of the problems it was to solve. Working two-way man-to-computer-to-man graphic communications dates back at least 10-20 years to the early Cape Cod and SAGE Air Defense Systems and Ivan Sutherland’s early SKETCHPAD system. Yet, even today, the amount of graphic output that most computer users ever see is limited to a few crude barcharts of graphs produced on computer printers, or possibly a pen-plot made with an electromechanical plotter. Everyone knows about computer graphics — but very few actually have it, and even fewer make good use of it in their normal day-to-day work.

Computer graphics has been too expensive. The hardware has been expensive but, far worse than that, the software has been actrociously expensive. It has been expensive not only in initial cost, but also in its tendency to be both highly specialized and highly machine-dependent. Only specially qualified assembly language programmers could work on it and it would work on only one machine. Obviously there were exceptions to this. Much of the great acceptance with pen-plotters received in recent years came from the fact that they permitted the use of FORTRAN subroutines which could be used by run-of-the-mill FORTRAN programmers to plot simple axes, graphs, etc. The more recent success of the TEKTRONIX storage tube terminals has also been greatly influenced by the fact that reasonably good user-accessible software is available for such devices.

Today we are in a period of rapid improvement in availability of practical computer graphics. Timesharing is bringing the computer out of the warrens of the computer center and into the offices of engineers, managers, classrooms, academic buildings, and even the dormitories of academia. Timesharing started out with printing terminals, like the teletype but the era of timesharing graphics is fast approaching. LSI and MOS technology are making the minicomputer and even the microcomputer increasingly attractive. Minicomputer-based special purpose graphics systems are now very successfully paying their own way in a number of tasks such as in the layout of electronic circuit boards. Coupled with small mass storage devices such as discs, or even in some cases cassettes, minicomputer-based graphics systems have considerable capability, in spite of serious software limitations. Today they seem ready to burst out into widespread use. Perhaps the most exciting possibility of all is the intelligent terminal connected by a communications link to a timesharing or other large computer system. In such an environment, the software advantages of the large system and the hardware advantages of the small system can complement one another, and can — potentially at least — gain the advantages of both.

But, enough of the past and the future. What can GCS offer today to the typical user — e.g., a routine FORTRAN programmer at an installation which has a limited amount of money to invest in graphics?

The USMA Graphics Compatibility System (GCS) is a FORTRAN-based computer graphics system designed for interactive use on a wide variety of computer graphics terminals. Due to its comprehensive and modular design, GCS provides a simplified easy-to-learn and easy-to-use approach to computer graphics, while simultaneously provid-
ing a powerfull tool which the sophisticated programmer may use for demanding and highly interactive graphical applications.

GCS provides compatibility at two distinct levels:

A. Cross-compatibility from one computer systems to another; and, 

B. Cross-compatibility between computer graphics terminals.

Cross-compatibility from one computer to another has been achieved by writing all GCS software in FORTRAN, with emphasis placed on strict adherence to the specifications established by the American National Standards Institute (ANSI).

Cross-compatibility from one terminal to another has been achieved in a manner which is completely transparent to the user. One need no longer be concerned about the problems of "tailoring" his programs for a given graphical device — GCS provides the maximum capabilities offered by the various terminals in order to satisfy the user's graphical requirements. Device independence provides the user with the option of preparing and debugging his graphics program on a terminal other than the type he may desire for final output — a consideration of paramount importance for installations which may have a limited number of graphical devices available at any given time.

It should be emphasized that GCS is not just another collection of unrelated graphics subroutines — it is a unified system which provides the user with the flexibility to perform his tasks at any level of involvement that he desires. Because of this unique man/software relationship, GCS can also be thought of as "user compatible," and it is in this last facet of compatibility that GCS unveils its true potential. Individuals who would normally dismiss graphics for their particular applications are now provided with an alternative. High-level, composite routines are provided to perform relatively complex but frequently required tasks such as the preparation of complete graphs and histograms. Flexibility and adaptability to the needs of the more sophisticated user are achieved by allowing such a user to control the various GCS options which are present to standard default conditions for the unsophisticated programmer. Users of all disciplines may feel equally comfortable with GCS, since they are required to interact only at their particular level of graphics involvement.

The GCS development was a response to a specific need. In the winter of 1971-72, it was decided that the U.S. Military Academy would teach a series of courses to senior R&D managers dealing with computer assisted design-engineering, with special emphasis upon interactive computer graphics.

It was decided that the course would be heavily, hands-on oriented and that USMA would demonstrate practical applications of graphics from each Math-Science-Engineering academic department area, programmed by a faculty member from that area. It was also decided that these applications should be spread over at least four types of graphics output:

1. Printer-plot graphics — both in batch mode and from a timeshare terminal.
2. Pen-plot graphics — both interactive and non-interactive.
3. Static or add-on CRT graphics — storage tube display.
4. Dynamic CRT graphics — refresh tube display.

The Army Material Command (AMC) was to supply adjunctive graphics equipment to add to the existing USMA Academic Computer Center timesharing systems: USMA was to provide the teaching faculty and develop both the educational software and the required
computer software; the U.S. Army Computer Systems Command was to provide a Liaison Officer who would assist in the computer software development.

The course was to begin in July 1972. The new graphics equipment would not be available until April or May. Terminal equipment would arrive so late that programs to run on one type of graphics terminal might have to be checked out by testing it on another type of terminal.

The academic department faculty members would not be available to work on the project until the start of June. Most of them were reasonably competent FORTRAN programmers with little, if any, prior experience with graphics — but most of them would have time to take a 6-8 lesson course in graphics during their lunch periods once a week in the spring semester.

In order to meet this near-impossible set of constraints, a system was devised which could be both quickly and easily learned by faculty members with varied levels of FORTRAN experience (and, in many cases, no FORTRAN experience) and could be built and checked out in a tremendous hurry, using no more than one or two full-time programmers, with part-time assistance of half a dozen or so other programmers.

GCS (Version 1.0) was the response. Somehow it was developed in time. It sputtered, wheezed, ran slowly, did not have very many sophisticated options, and had embedded in it various pieces of proprietary software which were not releasable to others. It was well accepted, however, by its users. It met the seminar requirements and was widely used during the Academic Year 1972-73, with a great deal of useful feedback being obtained. A year later, in the late spring of 1973, GCS version 2.0, rebuilt from the bottom up, became operational. It still ran the same program, with occasional minor changes suggested by users as human engineering improvements. It was faster, supported more advanced options, was much more solid, and no longer contained even the most remote trace of any proprietary software in its modules.

In October 1973, GCS had progressed to the stage that it was ready to release for field testing by other agencies. As a result of this field testing, some interesting and valuable suggestions were incorporated into GCS. In January 1975, the U.S. Military Academy was no longer able to support GCS and the responsibility for maintenance, distribution, and future development was transferred to the U.S. Army Corps of Engineers Waterways Experiment Station.
Chapter I

Important Technical Concepts and Conventions

In order to understand and use a system as powerful and versatile as GCS, the user should be aware of certain basic technical concepts and conventions.

Relationship of GCS to FORTRAN

The Graphics Compatibility System (GCS) is a package of inter-related subroutines written in ANSI FORTRAN. In order to produce graphics output, a FORTRAN program is written to perform whatever computations and/or graphics manipulations are needed to produce the desired image. Embedded in the program are calls to GCS subroutines to handle the graphic display and interaction, if relevant.

Under normal conditions, all input-output between the computer and graphics devices such as plotters and terminals will be handled via calls to GCS routines, without recourse to system dependent routines.

The programming conventions of GCS are identical to those of ANSI FORTRAN except that the use of GCS creates additional reserved names. All GCS subroutines designed for User use are FORTRAN subroutines beginning with the letter U. The GCS system also includes additional internal subroutines not intended for availability to users which always begin with the letters GCS. Thus the user, to avoid potential confusion and/or conflict between his program and GCS, should avoid creating his own subroutines with names beginning with either U or GCS.

All numbers used as calling parameters are passed to GCS as real numbers, even in situations where they represent integers.

Graphics Status Area (GSA) - Preset Modes and Parameters

In order to keep continuous track of many items of information relevant to graphics activities such as where the beam (or pen) is currently located, what portion of the screen (or plotting area) is currently within limits and what portion is currently off limits for drawing, what portion is within limits and what portion is off limits for textual material, etc, a labelled COMMON area GSA is established. The GSA common block also keeps track of the user's current choice from among the list of available options which define or mode of operation of the system.

When one starts a GCS program, the user's start routine (USTART) automatically sets all options to a standard initial condition: rectangular coordinate system, absolute (rather than relative or incremental), plotting angles to be measured in degrees, lines to be drawn routinely as solid lines without special attributes, etc.

The following is a sample program which illustrates the use of the GCS package to produce graphics output.

```fortran
DIMENSION X(2),Y(2)
A = 75.
B = 75.
X(1) = 25.
Y(1) = 75.
X(2) = 75.
Y(2) = 25.   COMMENTS
```
CALL USTART 'A'
CALL UOUTLN 'B'
CALL UMOVE (25.,25.) 'C'
CALL UPEN (A,B) 'D'
CALL UMOVE (X(1),Y(1)) 'E'
CALL USET ('DASH') 'F'
CALL UPEN (X(2),Y(2)) 'G'
CALL UEND
STOP
END

COMMENTS:

A: The first GCS call must be to USTART, a subroutine to initialize the status of the system.

B: UOUTLN will be explained in Chapter III.

C: All user oriented GCS subroutines begin with the letter 'U' and have easy to remember names.

D: Simple pen movements, such as visible UPEN's and invisible UMOVE's, are dependent upon the status of the system for their resulting actions.

E: All arguments to GCS subroutine calls are either real or character.

F: The status of the system can be modified, as in this case with USET, in order to obtain a wide range of output types.

G: The last GCS call must be to UEND, a subroutine which performs any termination activity.

GCS CONVENTIONS

Easy to remember English-language descriptions rather than arbitrary codes are used to specify modes. For example, if one is in the preset condition and wishes to draw in polar coordinates with angles measured in radians and lines drawn as vectors (solid lines with arrowheads), one would merely use the following User mode-Setting commands:

CALL USET ('POLAR')
CALL USET ('RADIANS')
CALL USET ('VECTOR')

To revert to drawing in rectangular coordinates with plain lines, the commands would be:

CALL USET ('RECTANGULAR')
CALL USET ('LINE')

Furthermore, there are those modes which require an additional parameter to be associated with that particular mode. For example, the preset polynomial degree to which a set of data can be fitted (using the subroutine ULSTSQ) is 5. If the user would prefer that his data be fitted to a polynomial of degree 3, he would use the User Parameter Setting command:

CALL UPSET ('POLYNOMIAL DEGREE';3)

(before the call to ULSTSQ). To re-establish the original polynomial of degree 5, the appropriate call would be:
CALL UPSET ('POLYNOMIAL DEGREE', 5.)

The user need never be concerned with these modes of parameters unless the standard values do not suit him. He can easily change them to values he wants. Then he can forget all about them until he once again feels a need to change, or until the GSA is reinitialized.

The underlying principle which permits the use of this option setting technique is the fact that the GSA is in fact a table containing all of the options necessary to define an environment in which graphics activities are performed. These elements are preset to values which reflect the most commonly performed graphics operations. In order to make a particular graphics option, only one element of the table is altered.

It will be normal practice in this manual to spell out completely the USET or UPSET option-names in full even if the name is very long, such as 'DOUBLEARROW' or 'DASHEDLINE'. Doing this is good form and good self-documentation for programs. GCS will, however, analyze only the first 4 characters in any option-name designator. If misspellings, truncations or non-standard wording occurs, the corrupted version will be fully acceptable to GCS provided that the first 4 characters of the character string are accurate.

With this system of organization, the beginning user—or the infrequent user—is insulated from the adverse effects which would tend to overwhelm the beginner in a system designed to provide flexibility for advanced and sophisticated users.

The user need be aware of, and pay attention to, only those degrees of freedom which he specifically wants to exploit in writing his program. GCS does not burden the user with long, complicated calling-parameter lists and complicated arbitrary codes. It can use short, easy-to-remember and easy-to-use commands convenient to both unsophisticated and sophisticated users.

Information in This Manual and Information Excluded From It

Some idea of the scope and range of the subroutines and options most likely to be of interest to the beginning user may be found in Appendices 'A' and 'B'. Sophisticated subroutines and options such as those involved in dealing with axis transformations, storing, manipulating and editing pictorial data structures have been completely omitted from this manual. Only a very limited subset of the most important and most frequently used subroutines and options from these appendices will actually be described in detail and discussed in this manual. For more complete programming information, see the separate 'GCS Programmer Reference Manual'.

i-3
CHAPTER II
GCS PROGRAMMING FUNDAMENTALS

Initialization
The first GCS statement in any program must be

**CALL USTART**

Its functions are many, varied and important. Some of them are:

A. It prepares the graphic terminal for plotting. In doing so, it clears the screen (or, in the case of plotter, requests the attendant to place a fresh sheet of paper on the plotbed), places the beam (or pan) in a standard position—coordinates (0,0) at the lower left corner of the standard plotting area.

B. It sets all mode and parameter options at their standard default values.

In the standard default condition, the system is set to use Cartesian, absolute coordinates and to draw solid lines in a large square area contained within the screen or plotting bed of the graphics device. It is preset to accept the values of 0. < X < 100. and 0. < Y < 100. Additional default settings by USTART will be mentioned later.

Reinitialization
At any time the initial default conditions can be restored by:

**CALL URESET**

Termination
It is necessary to perform various file and buffer termination activities upon exit from GCS by putting as the last GCS command of any program

**CALL UEND**

Use of this statement will insure that all GCS output is completed.

Erasing or Starting Off Again With a Clean Sheet
At various stages in running a program, it is often worthwhile to erase everything which has been drawn or printed on a CRT screen or to ask the attendant of a plotter to replace the old sheet on the plotter with a fresh clean one. The call for performance of this function is:

**CALL UERASE**

The pen position remains unchanged when erasure occurs.

Interactive Versus Batch
In a batch program there is no need to suspend execution in order to view multiple plots
prior to erasing or starting off again with a clean sheet. In an interactive program an
alarm can be sounded to indicate a plot is done by:

**CALL UBELL**

Then to allow viewing of the plot use:

**CALL UPAUSE**

**Simple Line-Drawing**

The basic command in GCS for drawing lines is

**CALL UPEN (X,Y)**

This routine moves the beam (or pen) from its present coordinate position \((X_0,Y_0)\) to a
designated new location \((X,Y)\). Pen status variables in the Graphics Status Area (GSA)
determine what kind of line (if any) is drawn as a result of this movement.

Until some sort of overt action is taken to change pen status, every UPEN movement will
cause a solid line to be drawn. (CALL USTART sets pen status to 'LINE'.) CALL USTART
also sets the initial beam (pen) position to \((0,0)\). Example II-1 shows a simple series of
CALL UPEN commands which will draw a square by 4 basic pen-movements.

**Invisible Lines**

If one wanted to draw a similar square starting at some location other than the origin, one
needs to be able to move the beam or pen invisibly, that is, without drawing any line. One
way to do this is to use the UMOVE subroutine

**CALL UMOVE (X,Y)**

The effect is identical to UPEN except that no line of any kind is drawn as the beam or
pen moves from the old location \((X_0,Y_0)\) to the new location \((X,Y)\). Example II-2 shows a
program which draws a square offset from the origin in this way. In this example we have
used subroutine UOUTLN to outline the square we are drawing within. (UOUTLN is
further explained in Chapter III.) The default origin is at the lower left corner \((0,0)\).

**Using a Pen Status Mode Change to Draw Invisible Lines**

The same effect as a call to UMOVE can be achieved by changing pen status mode from
its default condition to 'NOLINE' by means of a call to USET.

**CALL USET ('NOLINE')**

causes the system to again draw a line. Example II-3 shows a program which uses this
approach to draw the same image as Example II-2.

Another subroutine that is considered to be a simple line drawing subroutine, capable, if
desired, of producing an invisible line as in the example above. A call to

**CALL UPEN1 (X,Y,'NOLINE')**

enables the user to generate an invisible line to \((X,Y)\). The mode will be established as
indicated for only that 1 pen movement. Effectively, the above call is the same as the
CALL UMOVE \((X,Y)\), or of the CALL USET ('NOLINE'), CALL UPEN \((X,Y)\), CALL USET
`LINE` sequence. It will be shown throughout this text, however, that the chosen mode can be one of many different line modes other than 'NOLINE'.

**Pen Status Mode Changes Allow Many Kinds of Lines to be Drawn**

The UPEN subroutines of GCS can draw many other kinds of lines, including lines in various colors (if the plotting device permits), dashed lines, lines with tics along their length, and lines of all these types with various kinds of terminating characters or symbols. The number of permutations of line types and terminators to be used at the end of a line is very large. Some of the more important are demonstrated later in Chapter VI. However some of the basic options are considered below.

**Alternate Colors**

If the graphical device being used has the ability to display lines of different colors, the user can request that any subsequent line be generated with one of seven colors, using CALL USET (OPTION), where OPTION in this case is 'WHITE,' 'BLACK,' 'RED,' 'GREEN,' 'YELLOW,' 'BLUE,' 'MAGENTA,' or 'CYAN.'

Many terminals such as the Tektronix do not have a multi-color capability and, as such use the default color BLACK. Others, including most pen plotters, allow manual color change by replacement of the drawing pen by one of another color. A color mode change with such a device causes the plotter to position itself for pen replacement and a color change request to be typed out on the control device.

Most things done with colors can be done on devices which do not have a color capability by making distinctions through the use of plain lines, and various types of dashed lines, arrow lines, ticmarked lines and so forth.

**Vectors or Lines with Arrowheads**

One frequently useful set of options is the arrowhead options. These are useful for drawing vectors, dimension lines, etc. These use the following pen status modes:

<table>
<thead>
<tr>
<th>Pen Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'ARROW'</td>
<td>Draws a &quot;forward vector&quot; with its arrowhead at (X,Y)</td>
</tr>
<tr>
<td>'BACKARROW'</td>
<td>Draws &quot;backward vector&quot; with its arrowhead at (Xo,Yo)</td>
</tr>
<tr>
<td>'DOUBLEARROW'</td>
<td>Draws a &quot;dimension line,&quot; i.e., a line with arrowhead pointing out at each end.</td>
</tr>
</tbody>
</table>

Example II-4 demonstrates the use of the 'ARROW' option.

**Tic Marked Lines**

Another available option is tic lines, i.e., lines with tic marks at specified intervals along it. Pen status may be set to draw such lines by using a call to USET.

```
CALL USET ('TICLINE')
```

A call to UPSET

```
CALL UPSET ('TICINTERVAL',PARAMETER)
```
will change the interval along a ticline at which the tics will actually be placed. For example:

```fortran
CALL UPSET ('TICINTERVAL',5.)
CALL UOPEN (X,Y,'TICLINE')
```

will produce a ticline to (X,Y), marked off with tics at intervals of 5 units rather than the default value of 10. Example II-5 shows several ticline options.

### Dashed Lines

One can draw dashed lines by going to the 'DASHLINE' mode with a

```fortran
CALL USET ('DASHLINE')
```

The length of the dashes and or the intervals between the dashes can be modified, if desired, with a

```fortran
CALL UPSET ('SETDASH', DASHCODE)
```

the resulting dashed line will be repetitions of the effect caused by the combination of the digits (0-9) as follows:

<table>
<thead>
<tr>
<th>DASHCODE Digit</th>
<th>Effect on Visible Units</th>
<th>Effect on Invisible Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>-</td>
</tr>
<tr>
<td>2</td>
<td>-</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>-</td>
</tr>
<tr>
<td>4</td>
<td>-</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
<td>-</td>
</tr>
<tr>
<td>6</td>
<td>-</td>
<td>5</td>
</tr>
<tr>
<td>7</td>
<td>10</td>
<td>-</td>
</tr>
<tr>
<td>8</td>
<td>-</td>
<td>10</td>
</tr>
<tr>
<td>9</td>
<td>1 point</td>
<td>-</td>
</tr>
<tr>
<td>0</td>
<td>-</td>
<td>1 point</td>
</tr>
</tbody>
</table>

The specification of a single digit for DASHCODE will produce standard dashed (DASHCODE = 1-8) or standard dotted (DASHCODE = 9) lines. If the user desires a non-standard dashed line he must specify a DASHCODE of two or more digits, followed by a decimal point. The following sequence:

```fortran
CALL USET ('DASH')
CALL UPSET ('SETDASH',76.)
CALL UOPEN (X,Y)
```

will produce for example, a dashed line to (X,Y) consisting of 10 visible units, 5 invisible units, 10 visible units, 5 invisible units, etc. The physical length of a unit will be approximately 0.04 inches for the majority of the devices. Example II-6 illustrates several dashed line options. The number of possible types of dashed lines is limited only by the word length of the central computer.

### Polar Coordinates
The options absolute and rectangular (Cartesian) are established as defaults by USTART, because most drawings use this simple coordinate system. A polar coordinate system provides the user with the capability of referring to a location on the device in polar coordinates (R,THETA) rather than in rectangular coordinates (X,Y). Example II-7 illustrates use of polar plotting.

**Relative (Incremental) Plotting**

The relative coordinate mode interprets the coordinate pair of the pen request as units relative (positive or negative) to the previous pen position rather than as an absolute position. Example II-8 illustrates use of relative plotting.
THIS SAMPLE PROGRAM WILL DEMONSTRATE SIMPLE LINE-DRAWING BY DRAWING A SQUARE BOX IN 4 PEN MOVEMENTS

INITIALIZE GCS
THIS INITIALIZATION SETS GCS TO RECTANGULAR, ABSOLUTE COORDINATES, SOLID LINE PEN-DRAWING MODE, AND INITIAL PEN COORDINATES (0,0)

CALL USTART

NOTE THAT ALL GCS SUBROUTINES (INCLUDING THE UPEN ROUTINE USE TYPE REAL CALLING PARAMETERS. THUS COORDINATES MUST BE ENTERED AS REAL NUMBERS, I.E. WITH DECIMAL POINTS

MOVE PEN TO (0,50) THEREBY DRAWING LINE (0,0) to (0,50)
CALL UPEN (0.,50.)

EXAMPLE II-8
CHAPTER III
VIRTUAL AND DEVICE GRAPHICS

Outlining the Plotting Area

To obtain an outline of the area within which all graphical activity will be performed, the programmer may invoke the GCS subroutine UOUTLN:

CALL UOUTLN

Although the use of UOUTLN certainly is not necessary for most graphical applications, there are many times (particularly during the learning and debugging phases) when it is useful for the programmer to know the physical boundaries of the display he is generating.

The Default Case and Simple Extensions

The examples presented so far have assumed the use of variables which fall into the range of values:

\[ 0 \leq X \leq 100 \]
\[ 0 \leq Y \leq 100 \]

with no specific control over where on the screen (or plotting bed) the pictures are actually drawn. This is the default case established by USTART.

The user can easily change the range of permissible values to the ranges

\[ X_{MIN} \leq X \leq X_{MAX} \]
\[ Y_{MIN} \leq Y \leq X_{MAX} \]

by use of the command

CALL UWINDO (XMIN,XMAX,YMIN,YMAX)

This permits the user to plot anywhere in the space defined by the the four parameters in the subroutine call.

The values of the four parameters may be any FORTRAN real numbers permissible on the particular computer in use (subject only to the restriction XMIN .NE. XMAX and YMIN .NE. YMAX). See Example III-1.

Increasing and Decreasing Apparent Picture Size

Through the use of UWINDO, it is possible to increase or decrease the apparent picture size without having to change the values of the parameters required to generate the display. This facility effectively provides an elementary "zoom" capability which may be readily utilized under GCS. Example III-2 illustrates a simple six-step "zoom-out" by successively increasing the window specifications prior to generating each of the figures. Note that the pen commands required to draw the figure are identical in each of the six steps, and that the only dynamic entity is the window itself. Example III-3 illustr-
ates a six-step “zoom-in” through decrementing the virtual window. It should be noted that an increase in the window specifications decreases the apparent picture size (zoom-out) and that a decrease of the window specifications yields an increase in apparent picture size (zoom-in).

Distortion

It is important to note the ratio of the X-to-Y window specifications when defining new window boundaries, as ratios other than unity indicate that a distorted window will be constructed. Example III-4 illustrates this type of distortion by displaying the same basic information provided by Example III-3 with the exception that non-square windows are utilized.

Clipping the Edges of the Picture

Should the graphics programmer attempt to display information at coordinate locations which lie outside of the window boundaries, GCS will “clip” the display at the window boundaries and any graphical activity attempted outside of the boundaries will not be displayed. Example III-4 illustrates the clipping feature applied to a simple six-level “zoom-in”. We will again return to the topic of clipping after we first consider the concept of device coordinate addressing under GCS.

Expanding Flexibility and Capabilities: Device Mode

When desired, GCS provides means of very detailed control of where pictures are drawn on the physical device. This may be done by going to the ‘DEVICE’ mode with a

```
CALL USET ('DEVICE')
```

Thereafter all coordinates are measured directly in device measurement units from the lower left corner of the display screen or plotting bed.

Several optional units of measure are available on the display screen or plotting bed:

- **CALL USET ('CENTIMETERS')**: causes horizontal and vertical distances to be measured in centimeters.
- **CALL USET ('FONTUNITS')**: causes horizontal measurement in units of the width of standard alphabetic characters (usually the hardware characters for the device being used) and vertical measurement in units of the height of the alphabetic characters.
- **CALL USET ('PERCENTUNITS')**: cause horizontal measurement in units of a percentage of the full width of the screen or plotting bed and vertical measurement in units of one percent of the full physical height of the screen or plotting bed.
- **CALL USET ('RAS TERUNITS')**: causes horizontal and vertical measurement in terms of the smallest addressable unit for a particular device.
- **CALL USET ('INCHES')**: causes the horizontal and vertical measurement on the display to revert to the default case of inches.

See Example III-6
Viewporting: A More Flexible and Advanced Concept of Picture Control

Particular locations on the graphic device screen or plotting bed can be designated a device plotting area by the command

```plaintext
CALL UDAREA (XMIN,XMAX,YMIN,YMAX)
```

where XMIN, XMAX, YMIN and YMAX are measured in the currently defined units of measure in the device mode: inches, centimeters, percentunits, fontunits or rasterunits. Designation of this device plotting area has no effect in the device mode. However, in the virtual mode, either by default or by executing a call to USET ('VIRTUAL'), this device plotting area is at the heart of an extremely powerful concept of graphic control known as viewporting. This concept is most easily visualized by referring to the next figure while following the description below and the sample programs and their output.

The user may pick any scale or range of values desired to plot by means of a call to UWINDO. For example, to plot values in the range $0 < X < 1000$ and $0 < Y < 1000$, give the command

```plaintext
CALL UWINDO (0.,1000.,0.,1000.)
```

A call to UDAREA is used to specify where on the device to plot data. Then, plot in a 4-inch square at the left bottom of the display screen, first make sure that the unit of measure is 'INCHES' then give the command

```plaintext
CALL UDAREA (0.,4.,0.,4)
```

Next, make sure that the mode is 'VIRTUAL' and do any plotting desired. Any values within the "virtual window" $0 \leq X,Y \leq 1000$ is projected into the corresponding position of the "device plotting area" $0 \leq X,Y \leq 4$. For example, the user's numeric values of $Y = 0, X = 0$ would map into the lower left corner of the screen or plotting bed at position $X = 0, Y = 0$. User values of $X = 1000, Y = 1000$ would map into the upper right corner of the 4-inch device plotting area at $X = 4, Y = 4$. User values of $X = 250, Y = 750$ would correspondingly map into $X = 1, Y = 3$.

But what happens if the user tries to draw a line to a point outside the $0 \leq X,Y \leq 1000$ window, for example, $X = 250, Y = 1500$? Direct projection would indicate that such a line would rise vertically from the previous point to a point $X = 1, Y = 6$, but such a line would pass out of the designated device plotting area. What happens is that the line is 'clipped' off at the edge of the window, i.e., drawn only to the limit of the window (which is, of course, also the limit of the device plotting area). Thus if any other lines or textual material had previously been put into adjacent area just outside the designated plotting area it would be protected against being overwritten by data which was considered to be irrelevant because it fell outside the expressed values of plotting interest specified by UWINDO. This 'clipping' action associated with mapping from a virtual window to a specified device area adds markedly to the power and ease of pictorial control in GCS.

Here are some examples of the use of viewporting:

A. **Convenient Units**: the imaginary or expandable plotting area or virtual window can be defined to correspond to any convenient units which the user would like to think in terms of.

B. **Virtual Window Modification**: the user can selectively examine different areas of an entire display through the redefinition of the viewport followed by the pen movements of that entire display. This idea can also be used to examine a small area of a display in great detail.
C. *Device Window Modification:* the same display can be generated at many different locations on the device with the same pen movements by fixing the viewport and changing the device area, as illustrated in Example III-7. An extension of this device area modification capability allows the user to achieve distortions, as in Example III-8.

**Device Independent Plotting**

The previous examples that used subroutine UDAREA were written for a Tektronix 4010/4013 terminal. A device independent program can be written by using `PERCENTUNITS` or

```
CALL USTUD (ARRAY)
```
VIRTUAL OR IMAGINARY SPACE —

A USER'S CALL TO PEN MOVEMENTS ARE WITH RESPECT TO THE USER SPECIFIED VIRTUAL WINDOW.

DEVICE OR PHYSICAL SPACE (e.g., CRT, PEN PLOTTER, ETC.)

USER SPECIFIED DEVICE WINDOW

THESE PEN MOVEMENTS, IF WITHIN THE VIRTUAL WINDOW OF THE FIRST DIAGRAM, WILL ACTUALLY APPEAR WITHIN THE USER SPECIFIED DEVICE WINDOW OF THE ABOVE DIAGRAM.

VIRTUAL WINDOW

DEVICE WINDOW

THIS ACTUALLY OCCURS AS THE RESULT OF A MAPPING DIRECTLY FROM THE VIRTUAL WINDOW TO THE DEVICE WINDOW.

FOR EXAMPLE, THOSE PEN MOVEMENTS WHICH FALL WITHIN THIS PARTICULAR VIRTUAL WINDOW WILL ACTUALLY APPEAR WITHIN THIS PARTICULAR DEVICE WINDOW.

EXAMPLE III-9
Basic Alphanumeric Output

Under many circumstances, the graphics programmer would prefer to manipulate alphanumeric data with the same ease that pertains to strictly graphical information. Such a capability would expedite the labeling of figures, allow numerical values to be printed at a specific location on the display, and permit a discrete separation of text from graphical information should the user so desire. In order to provide these capabilities, GCS has incorporated two very powerful alphanumeric output and editing routines, UPRINT and UWRITE, which may be called by the following sequences:

```
CALL UPRINT (X,Y,DATA)
CALL UWRITE (X,Y,DATA)
```

X and Y are used to specify the starting position (in current units) of the first character of the output text. All positional and coordinate addressing related to characters is assumed to specify the position of the lower-left corner of the given character. DATA is interpreted in the following manner, based upon one of the four options available to the user through a call to USET before invoking UPRINT or UWRITE:

A. **TEXT**—Under this default option, the routines will assume that DATA contains Hollerith information delimited by a terminator and will output all text up to, but not including that delimiter, beginning at the location specified by (X,Y). CALL UPSET ('TERMINATOR', CHARACTER) can change the terminator from the default backslash character. There are four 'hardware' character sizes that can be changed by CALL USET(SIZE) where SIZE can be 'EXTRALARGE', 'LARGE', 'MEDIUM', or 'SMALL' (default).

B. **REALNUMBER**—DATA is assumed to be a single-valued parameter whose contents is assumed to be of type REAL. Editing will take place using 'G' format, and the text will be printed beginning at (X,Y).

C. **INTEGER**—As in the case of REALNUMBER, DATA is assumed to be single-valued and of type REAL. The routines will perform a REAL to INTEGER conversion and will print the result in 'I' format.

D. **XYCOORDINATES**—DATA is assumed to be a 2 element REAL array whose values specify two numbers to be edited and printed in the form: (X,Y).

UPRINT and UWRITE perform identical functions and differ only in the action taken upon return from execution of the given subroutine. Upon exit, UWRITE moves the beam position back to its original coordinates at the time it was invoked, whereas UPRINT leaves the beam position at the end of the output text. Example IV-1 illustrates the four options above.

Alphanumeric output through GCS is perhaps most conveniently manipulated through the use of FONTUNIT coordinates under DEVICE mode. Under this USET option, the (X,Y) coordinates are expressed directly in number of characters horizontally or vertically.

**Margining**

Since alphanumeric output through UPRINT and UWRITE can be 'clipped' when in 'VIR-
TUAL' mode the user is provided the capability to horizontally and vertically margin his output (when in device mode) through an invocation to UMARGN:

\[
\text{CALL UMARGN (XLEFT, XRIGHT, YBOTTM, YTOP)}
\]

XLEFT and XRIGHT represent the desired left-most and right-most horizontal positions expressed in DEVICE units within which alphanumeric output may be permitted. Maximum and minimum vertical margins are established by YBOTTM and YTOP respectively. Should values of XLEFT, XRIGHT, YTOP, and YBOTTM be specified such that XRIGHT < XLEFT or YTOP < YBOTTM, UMARGN will ignore the specified setting and the margins will reflect their values prior to the call to UMARGN.

Margining affects alphanumeric output (when in device mode) in the following manner:

A. Should any character extend beyond the right margin, an automatic carriage return and line feed are generated, followed by a position to the left margin and output resumed.

B. Should the user position the beam at a location to the left of the left margin, the beam is positioned to the left margin before output is initiated.

C. Should output be attempted at vertical positions outside the closed interval defined by the minimum and maximum vertical margins, the beam is moved to the maximum vertical margin before any output is begun.

See Example IV-2 for an example of margining.

**Bulk or Mixed Alphanumeric Output**

For applications requiring bulk or mixed alphanumeric output, the graphics programmer should consider the use of subroutine UPRNT1 and UWRIT1, which may be invoked by the following calling sequence:

\[
\text{CALL UPRNT1 (DATA, OPTION)} \\
\text{CALL UWRIT1 (DATA, OPTION)}
\]

OPTION is a single-valued character variable which specifies the format or mode under which DATA is to be edited and displayed; i.e., TEXT, REALNUMBER, GREEN, etc. DATA specifies the actual information which is to be output by UPRNT1 and UWRIT1 under the given OPTION. It should be noted that the constraints on DATA are identical to those imposed by UPRINT and WRITE.

UPRNT1 and UWRIT1 differ from UPRINT and WRITE in the following respects:

A. Since no coordinate specifications are passed in the calling sequence, the alphanumeric output will begin at the current beam position upon entry to the subroutine.

B. The effects of OPTION apply only to the current output operation and upon exit from the subroutine these effects are removed from the GSA.

**Fortran Input-Output**

For alphanumeric output used in interactive input-output communications and various control and coordination activities (such as the printout of warning or error notifications), the convenience of permitting the use of normal FORTRAN input-output statements may
Override the advantages of using UPRINT or UWRITE to process text. For such activities to be performed successfully, it is essential that the terminal device be set for the receipt of alphanumeric rather than graphic information, a task which is accomplished through a call to UALPHA. On systems that buffer the graphics output, UALPHA must be called prior to the Fortran I/O to flush the graphics output. It should be noted that all alphanumeric FORTRAN output is unaffected by the margins established by the user.

**Single Character Output**

In isolated instances, it is desirable to combine the output of graphical and alphanumeric information into one composite operation. This capability is provided through the 'CHARACTER' option available with UPEN, whereby a single printable character used as a parameter to USET identifies that parameter as the current character for printing. Thus, in order to print the character 'A' at (X,Y), the following commands would be specified:

```fortran
CALL USET ('LA')
CALL UPEN (X,Y)
```

Upon execution of the call to UPEN, the character 'A' will terminate the line drawn under the current line option. It should be noted that the CHARACTER mode of operation used in the above manner will remain in effect until any one of the acceptable UPEN suffixes is specified; e.g., CALL USET ('LNULL'). See Example IV-3.

An additional facility for single-character output is provided through subroutine UAOUT which is called in the following manner:

```fortran
CALL UAOUT (CHAR)
```

CHAR is a single character expressed in Hollerith format either as a quoted character string or as an explicit variable. Since UAOUT outputs the given character at the current beam position, the user should ensure that the beam is positioned to the proper coordinates before invoking UAOUT. Character output through UAOUT is subject to the current margin constraints applicable to UPRINT and UWRITE; in addition, this output differs from that available through UPEN in that UAOUT positions the beam to next character position after the specified character has been printed, whereas the UPEN option always maintains the beam position at the center of the desired character. See Example IV-4 and compare to Example IV-3.

**Software Character Output**

The preceding discussion of alphanumeric output has been applicable only to HARDWARE character generation. Under certain circumstances, however, the sophisticated user may desire character output which is rotated or scaled to suit a particular application. For examples see Example IV-5, and IV-6. This capability is provided in GCS through the SOFTWARE character option available through USET. Under this option, all output is subject to the constraints imposed by the virtual window, whenever UPRINT is called in 'VIRTUAL' space. Although SOFTWARE characters are manipulated using the same routines as those for output of HARDWARE characters, interested users are directed to the relevant subroutine writeups for a discussion of the limitations imposed on this form of output.
SAMPLE PROGRAM USED TO ILLUSTRATE OPTIONS AVAILABLE THROUGH 'UPRINT' AND 'UWRITE'. DEFAULT VIRTUAL WINDOW AND DEVICE AREA WILL BE USED.

FIRST ESTABLISH A 2-COORDINATE ARRAY: COORD(2). PUT SAMPLE DATA POINT (25.,0.9999999E19) IN ARRAY. NOTE THAT COORDINATES SPECIFIED IN ARRAY COORD ARE PRINTED. THEY MAY OR MAY NOT BE SAME AS COORDINATES WHICH SPECIFY WHERE PRINTING IS TO OCCUR.

DIMENSION COORD (2)
DATA COORD/25.,0.9999999E19/

CHAPTER V

GRAPHICAL AND ALPHANUMERIC INPUT

The following section discusses the facilities within GCS that are available for entering data of a graphical nature. Not all implementations of GCS can be used for such graphics input. For example, those implementations of GCS running in a batch mode, i.e., passive graphics, do not permit graphical input. For these applications, the routines discussed below are disabled.

For a graphics system to be truly interactive, it is necessary to provide the user with the ability of communicating information of a strictly graphical nature to his graphics program. Graphical input differs from conventional FORTRAN input (i.e., READ, etc.) in the following areas:

A. Graphical input is normally performed as a composite operation involving the transfer of positional coordinate information from the terminal's primary graphic input device (cursor, light pen, etc.) in conjunction with a single character from the keyboard (or other suitable interrupt) which signals the termination of the input operation.

B. Because of the unique nature of strictly graphical input, standard FORTRAN input cannot be used in lieu of software which has been specifically designed for that given purpose.

C. Graphical input does not produce any extraneous output at the graphics terminal when entering information, in contrast with standard FORTRAN free-formatted input which alerts the user through the use of a special symbol that input is requested, and echoes the input information as it is entered.

Positional and Character Graphical Input

The standard positional and character graphics input subroutine implemented within GCS is UGRIN, which may be called by the following sequence:

```
CALL UGRIN (X,Y,CHAR)
```

When UGRIN is invoked, the terminal's primary graphics input device is activated, and remains in an enabled state until a character is entered from the keyboard. Upon receipt of the character, UGRIN stores it into CHAR using standard FORTRAN Hollerith format, disables the primary input device, and transfers the positional coordinates (in current units) of the input device at the time the character was entered into X and Y. See Example V-1.

Subroutine UAIN functions in the same manner as UGRIN, except that no positional information is returned. Since the terminal remains in 'limbo' while awaiting input from the user, UAIN provides a convenient method of pausing at desired points during execution of a graphics program.

```
CALL UAIN (CHAR)
```

Alphanumeric Input (Fortran)

For bulk alphanumeric input used in conjunction with interactive communications and
coordination activities, standard FORTRAN may be utilized under GCS using the same criteria outlined in Chapter IV for FORTRAN alphanumeric output; i.e., the terminal must be placed into the alphanumeric mode through the call to UALPHA before control is relinquished to the FORTRAN input routines. It should be emphasized, however, that although FORTRAN input is extremely convenient, the use of FORTRAN input procedures significantly reduces the efficiency at which a graphics program executes; hence, the use of FORTRAN I/O should be avoided whenever possible.

Alphanumeric Input (Graphical)

An alternative method of alphanumeric input is provided to the graphics programmer through subroutine UREAD:

CALL UREAD (X,Y,DATA,COUNT,FLAG)

X and Y are used to specify the starting position (in current units) of where the alphanumeric input is to be attempted. UREAD will store the edited input into DATA, based upon one of the four options available to the user through a call of USET prior to invoking UREAD.

A. TEXT — Under this default option, UREAD will accept and store COUNT characters into DATA; hence, the user must insure that DATA has been suitably dimensioned to hold the number of characters which have been requested. Should fewer than COUNT characters be entered as input, UREAD will store the actual number of characters entered into FLAG, and blank-fill the remaining (COUNT - FLAG) characters of DATA. It should be noted that UREAD does not append the termination character to the end of the input. Therefore, the user is responsible for inserting this character via UAPEND if the string is to be passed as a parameter to UPRINT or UWRITE.

B. REALNUMBER — This option directs UREAD to edit the alphanumeric input as a REAL number, and to store the resulting floating-point number into the single-valued REAL parameter DATA. Should UREAD encounter any illegal characters during the edit, FLAG will be returned with a negative value, and DATA will be undefined.

C. INTEGER — As in the case of REALNUMBER, DATA is assumed to be single-valued and of type REAL. UREAD will edit the alphanumeric input as an INTEGER, perform an INTEGER to REAL conversion, and store the result into DATA. The user may check if the operation was successfully performed by examining FLAG upon return from UREAD.

D. XYCOORDINATES — This option directs UREAD to accept two REAL numbers (separated by a comma) as input and to store them into the two element REAL array, DATA. FLAG is set to reflect the status of the input and editing operation.

Under REALNUMBER, INTEGER, and XYCOORDINATES options, COUNT is used to specify the number of variables which are to be input under that given mode. For example, if two integers were desired to be read into DATA at virtual location (0.100.), the following call to UREAD could be used:

CALL USET ('INTEGER')
CALL UREAD (0.,100.,DATA,2.,FLAG)

Under XYCOORDINATES, COUNT designates the number of ordered pairs to be input.

A streamlined version of UREAD is available to the user under GCS through subroutine UINPUT:
CALL UINPUT (DATA,COUNT,FLAG,OPTION)

DATA, COUNT and FLAG are interpreted in the same manner as UREAD; OPTION is a single-valued character variable which specifies the format or mode under which the input is to be edited and stored into DATA, i.e., TEXT, REALNUMBER, INTEGER, etc. The UINPUT/UREAD relationship closely parallels UPRNT1/UPRINT in that the operation is performed at the current beam position, and the effects of OPTION are purged from the GCS upon exit from the subroutine. See Example V-2.

Menued Graphical Input

Aside from entering positional information which directs the generation of a display, the bulk of most interactive input requirements centers upon the ability to select one of several options which are 'menued' before the user. Menuing represents a very attractive means of user interaction due to the inherent simplicity of the required user response -- one need only position the graphic input device within the square of the menuboard which represents the desired option, and depress a character on the keyboard to transmit the selection to the user's program.

Within GCS, graphical input, by means of a menuboard, is facilitated through the use of subroutine UMENU, which is called by the following sequence:

CALL UMENU (PTSIN,LABELS,CHOICE)

The absolute value of PTSIN represents the number of menu options that will be provided (maximum of 10); LABELS is a character array containing one entry of up to eight characters which is to be printed under each menu option; and CHOICE is a single-valued output REAL variable, assigned a value by UMENU which indicates the box number of the option which the user has selected. When UMENU is called with a positive value of PTSIN, a menuboard is drawn, and the graphic input device is enabled. A negative value of PTSIN merely enables the input device and inhibits the redrawing of the menuboard. See Example V-3.

Drafting-Type Graphical Input

The three GCS graphical input subroutines described in this chapter represent a core around which many sophisticated interactive graphical programs may be designed. There exists one additional GCS graphical input subroutine, UDRIN, which permits high-level drafting-type activities to be performed under program control: in addition, the result of the man/machine interaction may be saved and recalled during future interactions.

CALL UDRIN(X,Y,CHAR)

Interested users are directed to the GCS Programmer's Reference Manual for further discussion.
C SAMPLE PROGRAM WHICH ILLUSTRATES GRAPHICS INPUT APPLICATION THROUGH 'UGRIN'. THREE TYPES OF CASES ARE HANDLED: SOLID 'S' INVISIBLE 'I', AND DASHED 'D' LINES. THE DESIRED OPTION FOR THE LINE IS ENTERED AS A SINGLE CHARACTER WHEN THE CURSORS HAVE BEEN POSITIONED. DEFAULT VALUES OF WINDOW, DEVICE AREA, AND DASH SPECIFICATION ARE USED. AN 'E' WILL TERMINATE THE PROGRAM.

CHARACTER CHAR*1
CALL USTART
CALL UOUTLN

ENABIES CURSORS, OBTAIN (X,Y) COORDINATES, AND THE CHARACTER.

CHAPTER VI
GCS UTILITY SUBROUTINES

To assist the user in preparing his graphical applications, GCS has incorporated a series of comprehensive, yet easy to use utility subroutines which permit the programmer to generate:

A. Circles and circular arcs
B. Regular polygons and other straight-sided geometric figures
C. Conic sections
D. Linear and least-squares polynomial curve fits to a series of user-supplied data points.

All of the GCS utility routines which generate graphical output perform their activities within the environment established by the user at the time they were invoked; hence, such output will be constrained by such parameters as the virtual window and device area, current units and mode of addressing, line type and terminator, together with any rotational and scaling factors specified by the user.

Circles

One of the most common requirements of scientific and engineering graphical applications is for the generation of circles and circular arcs. Provision for this capability under GCS is available through subroutines UCRCLE and UARC.

Circles may be generated through subroutine UCRCLE which is called by the following sequence:

CALL UCRCLE (X,Y,RADIUS)

X and Y are used to specify the coordinates (in current units) of the center of the circle of radius, RADIUS, which will be approximated by a series of line segments forming a many-sided equilateral polygon, whose peak deviation from an ideal circle is approximately 1.4 thousandths of the ideal circle's radius. This error is normally comparable in magnitude to the raster spacing of the plotting device, and should prove adequate under most conditions. Example VI-1 demonstrates the use of UCRCLE.

Circular Arcs

Circular arcs may be generated through subroutine UARC which is called by the following sequence:

CALL UARC (X,Y,ANGLE)

Upon invocation, UARC will generate an arc beginning at the current beam position and of angular span ANGLE. The radius of the arc is determined through computation of the distance from the center of the arc (specified by X and Y) and the beam position prior to entry into the subroutine. Upon exit, UARC will leave the beam at the last point of the angular segment it has generated. For example, if all default conditions are in effect, the current beam position is at (40.0,50.0), and UARC is invoked with the following parameters:
CALL UARC (40.0,20.0,90.0)

UARC will generate a circular arc having a center at (40.0,20.0), with a radius of 30.0, and angular span of 90.0 degrees. The arc will begin at (40.0,50.0) and terminate at (10.0,20.0). See Example VI-2.

Should the user be at a terminal which has the capability to generate circles and circular arcs via hardware, UCRCLE and UARC will utilize such facilities when they are invoked.

Regular Polygons

Polygon and other straight-sided geometric figure generation is provided through subroutines UPLYGN and URECT. Subroutine URECT may be utilized when a rectangle, which spans the area defined by the current beam position and coordinates (X,Y), is desired. Should URECT be called under the RELATIVE mode of addressing, any rotational or scaling parameters which may apply will dictate the rotation or scaling of the rectangle about the current beam position.

CALL RECT(X,Y)

Provision for the generation of equilateral (regular) polygons is available under GCS through UPLYGN which may be called by the following sequence:

CALL UPLYGN (X,Y,PTS,RADIUS)

X and Y denote the coordinates of the center of the polygon, PTS is the number of sides which is to comprise the figure, and RADIUS is used to define the radius of the circle within which the polygon is inscribed. With no relative rotation specified, the polygon will be drawn with one side parallel to the bottom of the plotting area. Should relative rotation be specified, this “base” side will be rotated by the given angle of rotation. In contrast to URECT, UPLYGN’s axis of rotation is defined by (X,Y) as opposed to the beam position upon entry to the subroutine. Examples VI-3 through VI-6 demonstrate the use of UPLYGN and URECT and illustrates some of the principles of rotation and line options.

Conic Sections

A particularly useful subroutine which may be used to draw all (or part) of a generalized conic section having a given focus, directrix, eccentricity, and angular span is available through the following calling sequence:

CALL UCONEC (X,Y,P,E,THETA1,THETA2)

(X,Y) are used to specify the coordinates of the center of the conic section; P is the distance from the focus to the directrix; E is the eccentricity, THETA1 and THETA2 represent the initial and final angles through which the conic section is to be drawn. Parameters E and P affect the generation of the conic section in the following manner:

A. \( E = 0 \)  will draw a circular arc with a center at (X,Y) and radius \( P/2 \). The arc will subtend the angular range defined by THETA1 and THETA2.

B. \( 0.\ LT.\ ABS(E).\ LT.1 \)  will generate an ellipse.

C. \( ABS(E) = 1 \)  will specify a parabola.

D. \( ABS(E).\ GT.1 \)  designates that a hyperbola is to be drawn.
indicates that the major axis of the conic section is to be oriented parallel to the X-axis.

specifies that the major axis is to be oriented along the Y-axis.

defines the position of the focus to be to the right of (or below) the directrix.

indicates that the focus is positioned to the left of (or above) the directrix.

Examples VI-7 and VI-8 demonstrate the use of UCONIC.

**Curve Fitting**

For those users who desire to combine data analysis through curve fitting into their graphical applications, subroutines ULINFT and ULSTSQ should provide of particular importance. ULINFT should be used when it is desired to obtain the slope (S) and Y-intercept (YI) of the linear equation, \( Y = SX + YI \), which represents the least-squares linear fit to a number (XN) of user-supplied data points (contained in arrays X and Y). ULINFT may be called by the following sequence:

```plaintext
CALL ULINFT (X,Y,SN,S,YI)
```

See Example VI-9.

Subroutine ULSTSQ should be used when a 'least-squares' polynomial curve fit is desired. ULSTSQ returns the N+1 coefficients of the polynomial of degree N which represents the 'best' in the sense of least-square fit to a series of user-supplied data points. ULSTSQ may be invoked by:

```plaintext
CALL ULSTSQ (X,Y,XN,COEFF)
```

where X is a user-supplied array containing XN values of the independent variable; \( Y \) is an array of XN values for the dependent variable; XN is the number of values in each of the X and Y arrays; and COEFF is an output array which contains the N+1 coefficients of the polynomial which was fitted to the data. In order to specify the degree of the polynomial which is to be fitted to the data, it is necessary to call UPSET before ULSTSQ is invoked. For the generalized case outlined above, a suitable call to UPSET would be:

```plaintext
CALL UPSET ('POLYNOMINAL',FLOAT(N))
```

See Example VI-10.

**Development of Applications Library**

There is one additional curve fitting routine available, USPLIN. This routine does a cubic spline fit to a series of data points. The quality of fit is established by the nature of the cubic spline function. The user is referred to the GCS programmer's reference manual.

```plaintext
CALL USPLIN(X,Y,XN,RX,RY,RN)
```

The subroutines discussed in this chapter represent a group of software which may be viewed as a miniature applications library.
SAMPLE PROGRAM USED TO ILLUSTRATE SIMPLE APPLICATION OF THE SUBROUTINE 'UCRCLE'. DEFAULT VIRTUAL WINDOW AND DEVICE AREA IS USED. NOTE THE EFFECT OF 'SCISSORING' DUE TO THE VIRTUAL WINDOW'S RESTRICTING OF ALL GRAPHICAL INFORMATION TO RESIDE WITHIN THE REGION DEFINED BY A 100.-BY-100. SQUARE.

CHAPTER VII
HIGH LEVEL GRAPHICS

High Level Plotting Facility

UPLOT is a general-purpose composite plotting subroutine which may be used to graph full-screen representations of complete arrays of data. Through the use of common default options, UPLOT provides sufficient flexibility to meet the majority of plotting requirements; however, should the user desire to change any of the applicable options, UPLOT will permit:

A. Rectangular, semi-logarithmic, log-log, or polar plotting;
B. Automatic or forced scaling of data values;
C. Axes presentation and format options, to include alphanumeric labeling.

UPLOT may be called by the following sequence:

CALL UPLOT (X,Y,CURVES, PARRAY, OPTARY)

CURVES is a single-valued variable which denotes the number of curves to be plotted. PARRAY is an array which describes the number of data points for each curve; e.g., PARRAY(1) is the number of data points comprising the first curve, PARRAY(2) is the number of points for the second curve, etc. OPTARY is a character array which specifies the data presentation format applicable to each given curve. Each element of OPTARY must not exceed 4 characters in length, and must represent a valid pen-status option such as 'LINE', 'VECT', etc. Since PARRAY and OPTARY follow the same general nomenclature in describing the characteristics of a given curve, both of these arrays must have as many elements as there are curves to be plotted. Arrays X and Y contain the actual data values grouped by curve. The size of the X and Y arrays must be equal to the sum of the elements of PARRAY. The general format of each of these arrays is outlined in the following figure.

Contents of Arrays Used in UPLOT

PURPOSE OF PLOT - Plot three curves having 8, 4 and 5 points each

For those users desiring to plot only a single curve using the current line type, there is a special form of UPL0T — UPL0T1 — which has a simplified calling sequence. UPL0T1 offers all of the various options available through UPL0T and may be called by the following sequence:

```
CALL UPL0T1 (X,Y,PTS)
```

X and Y are arrays containing the data values to be plotted and PTS is a single-valued variable indicating the number of points which comprise the curve.

The visual results obtained through UPL0T depend upon the status of the GSA at the time UPL0T is invoked. All of the high-level graphics parameters are assigned default values by USTART, and may be modified through conventional calls to USET and UPSET. Although many of these options will be presented, it is not the intent of this chapter to discuss each particular option in detail, further information may be found in the GCS Programmer's Reference Manual.

**Coordinate System Options**

The two types of coordinate systems applicable to UPL0T are specified through USET in the following manner:

```
CALL USET ('RECTANGULAR')
CALL USET ('POLAR')
```

Under RECTANGULAR coordinates, the user is given the option of specifying linear or logarithmic mappings of the independent and dependent variables: NOLOGAXES, XLOGAXES, YLOGAXES and XYLOGAXES. When logarithmic axes are specified, the user has the option of specifying the base of the logarithmic transform via a call to UPSET. This can be any real number, with 10 being default or the character string LIHE to denote the base of the Napierian logarithm. The call to UPSET is

```
CALL UPSET ('BASE' base)
```

where base is the base of the logarithms as described above.

**Scaling Options**

There are three options applicable to the scaling of data values for a graphical display under UPL0T: 'AUTOSCALE', 'FULLSCALE', and 'OWNSCALE'. Under AUTOSCALE, the range of values to be plotted is examined and scaling occurs so that the graph will be presented with 'nice' numbers at the tic marks on the axis (if requested). The FULLSCALE option resembles AUTOSCALE with the exception that 'nice' numbers may not appear. OWNSCALE uses the virtual window established by the user upon entry to UPL0T in order to scale the data values, hence, a zero-value is not forced on the X-axis. Thus, 'nice' numbers may not necessarily appear as numeric labels, and all of the data points may not be displayed should they extend beyond the window limits.
There are also two options relating to the calculation of the scale factors, 'NEWSCALE' and 'OLDSCALE'. With the 'NEWSCALE' option, the scale factors used to map the data onto the display screen is always recalculated. Specifying 'OLDSCALE' results in this calculation being bypassed, with the result that a scaling factor used in a previous plot is used for the current plot. This often results in an increase in speed at which the points are produced.

General Purpose Axes Creation

Subroutine **UAXIS** is invoked by subroutine **UPLOT** to generate the desired axes for the input data arrays. It is specified:

```plaintext
CALL UAXIS(XMIN,XMAX,YMIN,YMAX)
```

Axes Options

The options which apply to the axes may be further subdivided into the following categories:

A. Axes existence options.
B. Axes format options.
C. Axes positioning options
D. X and Y labeling option.
E. Numeric label format options.

'XYAXES', 'XAXIS', 'YAXIS', and 'NOAXES' comprise the USET options which specify the existence of an axis. **XYAXES** indicates that both X and Y axes are to be drawn, whereas the **XAXIS** or **YAXIS** options are be used when only one of the respective axes is desired. The **NOAXES** option will suppress the display of the X and Y axes, but will permit axis labelling should the user so desire. The existence or lack of any axis does not influence the scaling mode which the user has requested.

The axes format options consist of allowing the user to specify either 'PLAINAXES', **TICAXES**, or **GRIDAXES**. Under **PLAINAXES**, the specified axis (or axes) will appear as a solid line. The **TICAXES** option will force the axes to be drawn as ticked lines, with the tic intervals specified by the **UPSET** options:

```plaintext
CALL UPSET ('TICX',XINTERVAL)
CALL UPSET ('TICY',YINTERVAL)
```

XINTERVAL and YINTERVAL are single-valued REAL variables which specify the interval (in current units) at which tic marks are to appear on the X and Y axes respectively. Under the default values of zero X and Y tick intervals, **UPLOT** will choose suitable intervals based upon the axes existence and data scaling options specified by the user. The **GRIDAXES** option should be used whenever grid lines are desired for the axes which have been defined. The grid spacing will be determined in the same manner as the tic interval under **TICAXES**. Under **POLAR** coordinates, XINTERVAL defines the radial distance between concentric circles which comprise the grid lines for the R-axis; whereas, YINTERVAL specifies the angular increment at which grid lines which be drawn for the 0-axis.
The user may position his axes through the use of the following options: 'EDGEAXES', 'ZEROAXES', 'XZEROYEDGE', 'YEDGEXZERO', 'XEDGEYZERO', and 'YZEROXEDGE'. The EDGEAXES option indicates that the axis (or axes) is to be oriented near the edges of the currently defined device area. When the EDGEAXIS option is used in conjunction with XYAXES and OWNSCALE, UPLT will generate X and Y axes which intersect at the minimum values contained within the X and Y arrays. In addition, the axes will be positioned near the left and bottom edges of the device area. Should the minimum and maximum values of the X and Y arrays constitute an interval which contains zero, the ZEROAXES option may be used to force the intersection of the axes through the given zero point. Should ZEROAXES be specified, and zero is not contained within the defined interval, EDGEAXES will be generated. XZEROYEDGE, YEDGEXZERO, XEDGEYZERO, and YZEROXEDGE options are merely extensions of the EDGEAXES and ZEROAXES options, and are subject to the constraints outlined above.

The user is provided with the ability to control the format under which the X and Y axes are labeled through the use of the following options: 'NOXLABEL', 'XNUMERICLABEL', 'XALPHALABEL', 'XBOTHLABELS', 'NOYLABEL', 'YNUMERICLABEL', 'YALPHALABEL', and 'YBOTHLABELS'. 'NOXLABEL' and 'NOYLABEL' should be used when the labeling of the X and Y axes is to be suppressed. The 'XNUMERICLABEL' and 'YNUMERICLABEL' options indicate that numeric labels are to be created along the X and Y axes at the tic intervals specified by 'TICX' and 'TICY' respectively. The actual values for the numeric labels will be based upon the axes scaling options previously discussed. 'XALPHANUMERIC' and 'YALPHANUMERIC' allow the user to generate alphanumeric labels (or titles) for each axis. The actual information to be displayed is defined through a call to UPSET:

```
CALL UPSET ('XLABEL',XDATA)
CALL UPSET ('YLABEL',YDATA)
```

XDATA and YDATA are strings of up to 40 characters in length, with the standard string termination character inserted at the end of the information. The XBOTHLABELS and YBOTHLABELS options are used when numeric as well as alphabetic labels are desired.

The user is provided with the ability to control the format under which numeric labels will be printed through the use of the 'BESTFORMAT', 'IFORMAT', and 'GFORMAT' options. Under 'IFORMAT', 'EFORMAT', all numeric labels will appear as integers, with truncation occurring for any non-integral values. EFORMAT and GFORMAT will generate labels which will be edited into either standard FORTRAN 'E' or 'G' formats respectively. BESTFORMAT implies that the numeric labels are to be output under the format which is most appropriate for the given label.

**Time Series Axes**

In addition, there is the axes routine, UTAXIS, that permits the user to select, scale and label time series axes. For further information on this routine, see the subroutine description section. It is specified:

```
CALL UTAXIS(BEGPER,PERIOD,YMIN,YMAX)
```

**Curve Fitting Options**

UPLT provides an additional facility for those users desiring to fit linear, least-squares polynomial, and spline curves to their data points. Interested users are directed to the detailed descriptions of UPLT, ULSTSQ, and ULINFT contained within GCS programmer's reference manual.
Extended High-Level Graphics

For data presentation formats extending beyond those available through UPLIT and UPLIT1, a series of generalized histogram, barchart and piechart utility subroutines have been incorporated into GCS. These subroutines are comprehensive enough to permit their utilization as the core of a complete data analysis and display program; without compromising the versatility to be incorporated into a graphics program within which they play a relatively minor role.

Histogram generation facilities are provided through the use of subroutine UHISTO:

```
CALL UHISTO (DATA,XN,CELLS)
```

DATA is a REAL array containing the data values from which the histogram is to be constructed; XN is a single-valued REAL variable which is used to specify the number of elements in the DATA array; and CELLS is a single-valued REAL variable which designates the number of cells (or bars) which are to appear on the histogram. The standard axes existence, labeling and scaling options previously discussed for UPLIT also apply to UHISTO, with the exception of the GRIDAXIS option for the X and Y axes, and 'TICAXIS' for the Y axis.

Subroutine UBAR may be invoked whenever the user desires to generate a barchart.

```
CALL UBAR (DATA,XN,LABELS,SLABEL)
```

DATA and XN are interpreted in the same manner as described above the UHISTO. LABELS is a character array which is used to specify the label for each XN values stored in DATA. SLABEL is a single-valued REAL variable which defines the length (in characters) of each element of the LABELS array. Should UBAR encounter the standard string termination character (;) while processing any of the label items, no additional characters are obtained from the item and the string prior to the terminator is scaled to a string of SLABEL characters in length.

Subroutine UCHART may be invoked whenever the user desires to generate a grouped bar chart for multi-valued data.

```
CALL UCHART(ARRAY,GROUPS,BARS,LABELS,YMAXL)
```

Standard piechart generation facilities are available under GCS through subroutine UPIE which may be called by the following sequence:

```
CALL UPIE (DATA,XN,LABELS,SLABEL)
```

DATA, XN LABELS and SLABEL are interpreted in the same manner as under UBAR.
SAMPLE PROGRAM USED TO ILLUSTRATE APPLICATION OF SUBROUTINE 'UPLOT1'. EIGHT CURVES WILL BE PLOTTED IN POLAR COORDINATES, USING THE SINGLE-CURVE POLAR PLOTTING ROUTINE. THE PURPOSE OF THIS EXAMPLE IS TO ILLUSTRATE THE USE OF THE HIGH-LEVEL SUBROUTINE TO PLOT SINGLE CURVES WITHIN THE USER-DEFINED DEVICE AREA. NO AXES OR AXES LABELING IS REQUESTED. THIS WAS WRITTEN FOR A TEKTRONIX 4010/4013 TERMINAL.

INITIALIZE CONSTANTS AND ANGLES

```c
DIMENSION R(361), THETA(361)
DATA PI, W, YO/3.1415925, 0.0, 4.71/
DO 1 I = 1, 361
   THETA(I) = FLOAT(I) * PI / 180.0
```

ENTER GCS, SET FOR POLAR, RADIUS MEASURE, NO AXES AND NO LABELS.

```c
CALL USTART
CALL USET ('POLAR')
CALL USET ('RADIANS')
CALL USET ('NOAXES')
CALL USET ('NOXLABEL')
```

INCREMENT LOCATION OF DEVICE PLOTTING AREA, AND PLOT THE FIGURES.

```c
DO 2 I = 1, 2
   XO = -1.5
   YO = YO - 1.8
   W = W + 0.5
   XO = XO + 1.8
   CALL UDAREA (XO, (XO + 1.5), YO, (YO + 1.5))
   CALL UOUTLN
   DO 3 K = 1, 361
   2 R(K) = 1.2 - 0.7 * (ABS(COS(W * THETA(K))) - ABS(SIN(W * THETA(K))))
```

PLOT 361 DATA POINTS SPECIFIED BY 'R' AND 'THETA' USING THE STANDARD LINE OPTION WITHIN THE DEVICE AREA WE HAVE DEFINED. NOTE THAT NO AXES OR AXES LABELING WAS SPECIFIED.

```c
CALL UPLLOT1 (R, THETA, 361.0)
```

EXAMPLE VII-1

CHAPTER VIII
COORDINATE SYSTEMS AND TRANSFORMATIONS

An Overview of GCS Coordinate Systems

The GCS coordinate system options have been designed to provide adequate flexibility for the user in order to enable him to work in whatever type of coordinate system environment is most natural and convenient for him to use at a particular point in his program. There are several areas in which basic options exist; however, it is imperative that the user fully understand the basic coordinate system under GCS before attempting to alter any of the default options.

The GCS default coordinate system which is defined at the start of a GCS program (via a CALL USTART) is a simple, pre-defined Cartesian (rectangular) X-Y coordinate system. No special options such as semi-logarithmic or log-log plotting are in effect. Axes are not rotated with respect to the screen or plotbed and no special scaling options are in force. Distances are measured from the origin, not incrementally from the last point plotted. As described in Chapter III, any drawing done in this coordinate system may be viewed through an adjustable size window which can automatically clip off irrelevant or distracting parts of the picture.

A GCS programmer may specify that he wishes to use one of three coordinate systems when working in two dimensions:

- Cartesian (rectangular)
- Log-log or semi-logarithmic rectangular
- Polar coordinates.

Points or lines to be plotted may be identified either by absolute coordinate position or relative to the last plotted point (incremental). The scale at which plotting is to occur may be user-specified in virtual space which can be projected onto the plotting device at any desired scale or it may be directly controlled in terms of dimensions of the plotting device. These dimensions may be specified in inches, centimeters, font-units (alphanumeric character heights and widths) percent-units, or raster units.

In addition to the basic or SYSTEM axis, the user may define any number of secondary USER axis systems which may be rotated, translated, and scaled differently from the SYSTEM axis. Such secondary USER axes may be defined relative to the basic SYSTEM axis or relative to a previously defined USER axis. This feature facilitates the definition of complex coordinate systems where, for example, one moves freely from coordinates based upon a location on a satellite circling the earth. Similarly, the use of simultaneously maintaining a secondary axis whose origin is a point on the curve, oriented controlled independently of one another and defined either with respect to the SYSTEM axis or cumulatively based on successive transformations on a series of different USER axes. Since the rotations and scaling in GCS are accomplished by standard matrix operations one can obtain mathematically accurate visual representations of highly abstract vector spaces such as those common to many linear programming applications.

Coordinate System Definition

In order to provide the capabilities discussed above, GCS has incorporated a very powerful secondary axis system which allows the user to define a new axis origin. The new origin can be displaced from the current origin, oriented about the new center point, and/or have a different unit length for the X and for the Y axis. The new axis is defined through subroutine UCOSYS which is called by the following sequence:
CALL UCOSYS (DX,DY,SCLX,SCLY,ANGLE)

DX and DY are used to specify (in current units of the current coordinate system) the position of the origin for the new axis. SCLX and SCLY define the scale of the new axis unit lengths with respect to their sizes in the current axis system. ANGLE is used to specify the rotation (in current angular units) of the new axis about its origin.

The key rule to be remembered is that every axis system has an origin which is coordinate location (0.,0.); all rotation occurs about this center point. The SYSTEM origin is the primary origin for the default axis system. In virtual space, the SYSTEM origin is at virtual location (0.,0.); this location may or may not be within the window defined by the user. In device space, it is a point on the display surface (usually at the lower left corner) which is at raster position (0.,0.). At any time, the user can insure that his coordinate addressing is interpreted with respect to the primary origin by making the following call to USET prior to addressing:

CALL USET ('SYSTEMAXIS')

To request that coordinate specifications be interpreted with respect to the user's current axis system, the following option is used:

CALL USET ('USERAXIS')

The default user axis coincides with the system axis. When a new user axis is created by subroutine UCOSYS, the GCS status is automatically switched to 'USERAXIS'. When UCOSYS is invoked, there are actually two USER axes created. They are either identical to each other, or one 'lags' (in a mathematical sense) behind the other by one USER axis definition. One of these USER axes is called the WORKING axis and the other is called the REFERENCE axis. The REFERENCE axis is identical to, or 'behind' the WORKING axis. Under default conditions, the REFERENCE and WORKING axes are identical to each other; furthermore, these axes initially coincide with the SYSTEM axis. When a new USER axis is defined, it is created from the REFERENCE axis and entered as the WORKING axis transform. If UCOSYS is in the cumulative mode, then the new WORKING axis definition is placed back into the REFERENCE axis transform. Thus, the REFERENCE axis may be viewed as a permanent axis, while the WORKING axis may be considered as only temporary in nature.

When multiple coordinate systems are specified by the user, the new axis is computed independently of the previous USER axis. This is the new axis which is computed from the last permanent axis (usually the SYSTEM axis) and replaces any previously defined USER axis. This feature, which is the default condition under GCS, is selected by the following call:

CALL USET ('WORKINGAXIS')

For advanced problems, the user may wish to define multiple coordinate systems that are computed on a cumulative basis. That is, the new axis is computed from the last permanent axis, and becomes the new permanent axis. This option may be specified through the following call:

CALL USET ('REFERENCEAXIS')

There exist several useful subroutines within GCS which are subsets of subroutine UCOSYS, and facilitate the definition of a secondary axis at the current beam position. Subroutine UROTAT creates a new axis rotated about an origin defined by the current beam position. Subroutine USCALE defines an axis at the current beam position having a specified X axis and Y axis scaling. Subroutine UORIGN defines a new axis at the current beam position with no change of scale or orientation. These subroutines may be invoked by the calling sequences:
CALL UROTAT (ANGLE)  
CALL USCALE (SCLX,SCLY)  
CALL UORIGN  

ANGLE, SCLX, and SCLY are interpreted in the same manner described for subroutine UCOSYS. After the subroutines are invoked, the current beam position is associated with coordinate location (0.,0.).

In certain situations, such as the display of unrelated objects, multiple independent secondary axis transformations must be created simultaneously. In order to operate upon and modify one system, it is necessary to save the previous system and later restore it as needed. This facility is available under GCS through the use of the following subroutines:

CALL USVTR (ARRAY)

which is used to save the current transform, and

CALL UNSVTR (ARRAY)

which is called in order to restore a transformation from the array ARRAY, where ARRAY is a 21 word dimensioned variable. Note that a call to USVTR does not affect the status of the Graphics Compatibility System, but that a call to UNSVTR causes the restoration of all variables and switches to the values that they held when the companion USVTR was invoked. The user should not attempt to invoke UNSVTR for an array without previously saving a transform into that array by use of USVTR.

The secondary axis transformation feature of GCS is a very powerful mathematical system which is quite useful to the beginning as well as advanced graphics programmer. However, certain combinations of axis composition and specification will produce results which are mathematically correct but not easily understood. For example, the composition of a cumulative axis from an axis with non-uniform X and Y scaling will introduce a skew factor. For additional information on the secondary axis implementation under GCS, interested users are directed to the subroutine description section.
SAMPLE PROGRAM USED TO ILLUSTRATE THE USE OF GCS SUBROUTINE 'UCOSYS'. TWO DISPLAYS WILL BE DEFINED: A TRIANGLE WILL BE PLOTTED IN THE DEFAULT COORDINATE SYSTEM; AND A SQUARE WILL BE DRAWN IN A USER-DEFINED SECONDARY AXIS SYSTEM.

ENTER GCS, DEFINE A NEW VIRTUAL WINDOW, AND OUTLINE WINDOW.

CALL USTART
CALL USET ('WORKINGAXIS')
CALL UWINDO (-10.,10.,-10.,0.)
CALL UOUTLN

PROVIDE PEN COMMANDS TO DRAW A TRIANGLE IN THE DEFAULT GCS COORDINATE SYSTEM.

CALL UMOVE (0.,0.)
CALL UPEN (2.,0.)
CALL UPEN (0.,2.)
CALL UPEN (0.,0.)

DEFINE A SECONDARY AXIS WITH AN ORIGIN AT (5.,4.), HAVING THE SAME X AND Y SCALE FACTORS AS THE DEFAULT SYSTEM, AND ROTATED BY 45 DEGREES.

CALL UCOSYS (5.,4.,1.,1.,45.)

PROVIDE PEN COMMANDS TO DRAW A SQUARE WITHIN THE SECONDARY AXIS THAT WE HAVE JUST DEFINED.

CALL UMOVE (0.,0.)
CALL URECT (3.,3.)

WRAP-UP GRAPHICS ACTIVITY AND TERMINATE THE FORTRAN PROGRAM.

CALL UEND
STOP
END

CHAPTER IX
THREE DIMENSIONAL GRAPHICS

The three dimensional version of GCS gives to the user the ability to describing his environment in three dimensions. Each of the primary two dimensional GCS routines have a three dimensional counterpart: U3PEN, U3MOVE, U3DRAW, U3PRNT, U3WRIT, U3CSYS, and U3WHER. The coordinates used by each of these routines may be specified as (X,Y,Z) rectangular coordinates, (R,0,Z) cylindrical coordinates, or (R,0,t) spherical coordinates. Use of the 3-D routines does not preclude use of the 2-D routines; the 2-D routines are defined so as to draw parallel to the current X-Y plane on a plane specified by a default Z coordinate, contained in the Graphics Status Area (GSA). This Z value may be set by the user with an UPSET ('ZVALUE', value) call. The default ZVALUE is zero. By using both 2-D and 3-D routines an image may be described in 3-space.

In order to specify the appearance of the object being drawn, the location of the viewer and the direction in which he is looking must be specified. By calling UVIEW (XVIEW,YVIEW,ZVIEW,XSITE,YSITE,ZSITE), the user can specify where the view point is located and at what point in the environment he is looking (view site). The environment will then be displayed from this viewpoint with the view site located on a line which passes through the center of the viewport. The viewport indicates the boundaries of the user's field of view and also how far the viewport is from the view point or the viewsite. The X-coordinates of the viewport will range in the interval (-A/2,A/2) and the Y-coordinates in the interval (-B/2,B/2). Default values for UVIEW are (0.,0.,150.,0.,0.,0.) and for UVWPRT are (200.,200.,0.). GCS will also automatically clip points outside of the viewing pyramid (behind the view point or outside the viewport). The user can select whether the resulting image will be mapped to the screen with a PERSPECTIVE (default) or ORTHOGONAL projection.

The user may specify which portion of this viewport will be displayed on the screen by setting his UWINDO. The UWINDO boundaries may or may not overlap the viewport. If no portion of the UWINDO corresponds to the viewport, the viewport will be expanded to encompass the UWINDO if the UWINDO changes. If the viewport is specified smaller than the UWINDO, the UWINDO will contract to encompass the viewport.

As in 2-D GCS, the user may construct arbitrary user coordinate systems using the calls U3CSYS, U3SCAL, and U3ROTA. These work similar to the 2-D case with one exception. Since 3-D rotations are not commutative, the order of rotation must be specified with a suitable USET call: 'XYZ', 'XZY', 'YXZ', 'ZXY', or 'ZYX'. The default sequence is 'ZYX'.

A call to the 2-D routine UCOSYS will cause a rotation about the Z axis. Any rotation around other than the system Z axis will cause the XY plane to cease being parallel to the screen and will effect the output of symbols and curves (see below).

Curve generation using the UARC, UCRCLE, UCONIC, UPLYGN, and URECT routines function as they did before. However, since they are 2-D routines, their output will be created in the XY plane specified by the current ZVALUE parameter as indicated above. In addition, software characters generated by U3PRNT, U3WRIT, and UAOUT will also appear in the XY plane. Hardware characters still appear on the plane of the display surface. Line terminators (arrowheads and software characters) and tic marks appear on a plane specified by the two end points of the line and a third point which the user can specify via the UPOINT(X,Y,Z) subroutine. The default UPOINT is a point on the default XY-plane outside the default UWINDO boundaries. This point is (-6931471806, -1.096122887, 0.).

Textual output for three dimensions has been expanded slightly to allow another text output mode. This mode is 'XYZCOORDINATES' which will print the three components
of a set of 3-D coordinates. 'XYCOORDINATES' are still available for 2-D coordinates. All other text functions of 2-D GCS are processed as before. Since the text created by U3PRNT and U3WRIT is displayed in the current user X-Y plane, specified by the Z-coordinate of the specified location, suitable choices of UVIEW will result in text which when displayed will be backwards. This is a result of viewing the text from behind it.

Drawing 3-D images is primarily intended for use in VIRTUAL space. However, a user who wishes to do so can directly address the face of the display surface in DEVICE space. If this is done, no clipping against viewport boundaries takes place. The requested graphical data is displayed projected orthogonally onto the device screen. For most devices, the Z-value will be ignored and the X,Y components will be used as screen addresses after conversion to device units.

To facilitate displaying different sections of the viewport, an additional window and display area routine has been implemented. ULOOK lets the user specify a portion of the display surface (UDAREA) in device units. The window (UWINDO) dimensions are then adjusted to move the UWINDO to display the equivalent portion of virtual space (viewport). The effect is that of moving a template around on the viewport.
THIS PROGRAM DEMONSTRATES THE USE OF SEVERAL 3-D SUBROUTINES AND THE DIFFERENCE BETWEEN ORTHOGONAL AND PERSEPECTIVE PLOTTING.

CHAPTER X

GRAPHICAL DATA STRUCTURE PROCESSING

A feature which is contained within 3D GCS is the ability to create, save, and later recreate pictures as they are drawn. It permits the user to specify the description of a commonly used graphic image once, store it, and then invoke this description whenever necessary. This facility is the implementation of an internal high-level GCS data structure.

Before the user can define or use a data structure, he must first provide a work file for GCS to use. This work file can be specified by an UPSET ('LIBRARYFILE', file number) call. The file will then be used to maintain the user's currently active library of GCS graphics data structures.

To build a data structure, the user must first call a routine USTRCT (NAME) which initiates construction of a data structure under the specified name. From then on all calls to the GCS routines listed in Table X-1 will be saved as elements of the data structure. Whenever the specification of the object has been completed, a call is made to UTERM (NAME) to terminate the building process. The resulting data structure is then stored on the library file. During the building process, the build mode may be turned off by specifying 'NOBUILD'. Construction may be resumed by then specifying 'BUILD'. 'BUILD' is automatically specified when USTRCT is called and 'NOBUILD' is set when UTERM is called. Normally, the structure being built will be displayed during the construction process. If the user does not wish to view the structure he may specify 'NOEXECUTE'. If this is done, the structure element will be saved but no visible output will appear. The user may return to viewing his construction process by setting 'EXECUTE' which is the default mode.

To invoke an already created structure, the user uses the U3CALL or UCALL routines specifying the name, position, and orientation of the data structure. The data structure specified will be displayed as indicated. If another structure is currently being built when this call takes place, a U3CALL structure element for the invoked structure will be inserted in the active structure.

When the user terminates the GCS program, he may wish to save his library file so it can be restored at a later time. A routine called UTILITY is used to perform several utility functions concerned with maintaining the library file. To save the current library file, the user simply invokes UTILITY ('SAVE', file number). This file number must be different from the library file. All data structure contained in the library will be reformatted into a standard Hollerith card format and written to the save file. To restore a saved file to the library file, the UTILITY ('LOAD', file number) function would be used. Other UTILITY functions exist to MERGE a save file into the existing library file, PURGE the existing library file, and DELETE or RENAME structures in the library file.

CHAPTER XI
PICTURE SEGMENTATION AND NAMING

Refresh Graphic Facilities

Many computer graphics display applications require only a static display in order to convey information. That is, the complete picture provides all of the relevant information that can be derived from the data used to produce the display. In some situations, however, a static display provides incomplete information. For example, the plot of a missile trajectory does not reveal the relative speed of the projectile while in flight. In such situations, a dynamic display which portrays motion provides more information to the user than does a static display. GCS provides a facility for the dynamic display of information and for selective erase of information on refresh graphic display devices if available. The facility allows the user to identify and bracket a portion or portions of his display, assign a name to the section, turn the named section on or off, and replace a named section with a new definition of the section.

The basic unit of information of a dynamic display is the 'frame'. A frame represents a portion of a display having a known origin and a known termination. The GCS subroutines which delimit the start and the end of a frame are UFRAME and UFREND. They are invoked as follows:

CALL UFRAME (NAME)
CALL UFREND (NAME)

where NAME is an eight character alphanumeric variable or constant. The subroutine UFRAME indicates the starting point of the framed information and subroutine UFREND denotes the ending point. Note that multiple frames may be defined, but nesting of frames is not permitted; that is, subroutine UFREND must be called to 'close' the current frame before the subroutine UFRAME is invoked to 'open' another frame.

Whenever a UFRAME/UFREND pair are invoked to replace the previous occurrence of the named frame, the previous occurrence is deleted upon completion of the new version of the frame, as signalled by the call to UFREND for that frame. Thus the complete frame will replace the previous complete frame. This is the default condition in GCS and is known as 'invisible' building of a frame. It can be specified by the following invocation to USET:

CALL USET ('INVISIBLE')

For some dynamic graphic applications, it is preferable to see the frame being built line-by-line. In this case, the previous frame must be deleted when the call to UFRAME is made for frame redefinition. The user can request the visible building of a frame by the following call:

CALL USET ('VISIBLE')

After a frame is completely built, and terminated by a call to UFREND, it may be selectively 'turned on' and 'turned off' by the use of the following GCS subroutines:

CALL USHOW (NAME)
CALL UNSHOW (NAME)

where NAME is the eight character alphanumeric variable or constant which is the name assigned to the frame upon which the operation is to be performed. When USHOW is invoked for an invisible frame, the frame is made visible; if UNSHOW is invoked for a visible frame, the frame is made invisible.
Note that the GCS subroutine UERASE affects the status of frames by completely removing all frames and frame names from GCS. Thus if USHOW or UNSHOW are invoked after a call to UERASE, an error will be indicated. In addition, it is improper to call UERASE while a frame is 'open', i.e., after a call to UFRAME and before a call to UFREND.
SAMPLE PROGRAM USED TO ILLUSTRATE MULTIPLE ENTITY FRAMING.

INITIALIZE VARIABLES, ENTER GCS, OUTLINE VIRTUAL WINDOW.

X = -10.0
Y = 80.0
CALL USTART

3 CALL UEND
STOP
END
SAMPLE PROGRAM USED TO ILLUSTRATE ELEMENTARY FRAMING AND ROTATION. THE ROTATIONAL TECHNIQUE EMPLOYED IN THE PROGRAM IS QUITE LIMITED, HENCE THE USER IS DIRECTED TO USE THE GCS SUBROUTINE 'UCOSYS' FOR APPLICATIONS REQUIRING MORE ROTATIONAL CAPABILITIES.

INITIALIZE VARIABLES, ENTER GCS, DEFINE NEW VIRTUAL WINDOW, AND OUTLINE IT.

DATA DEGREE/0.0/
CALL USTART
CALL UWINDO (-50.,50.,-50.,50.)
CALL UOUTLN
CALL UPSET ('LIBRARY', 1.)

SPECIFY THAT POLAR COORDINATES ARE TO BE USED TO SIMPLIFY THE PROGRAM, AND DEFINE LOOP TO DRAW A SQUARE DYNAMICALLY.

CALL USET ('POLAR')
DO 11 = 1,12
DEGREE = DEGREE = 30.0

INDICATE THE BEGINNING OF FRAME DEFINITION FOR THE SQUARE, AND PROVIDE THE NECESSARY COMMANDS TO ROTATE AND DRAW IT.

CALL UFRAME ('SQUARE')
CALL UMOVE (25.,DEGREE)
CALL UPSET ('ROTATE',DEGREE)
CALL USET ('RELATIVE')
CALL UPLYGN (0.,0.,4.,5.)
CALL USET ('ABSOLUTE')

INDICATE THE TERMINATION OF THE SQUARE FRAME, AND THE LOOP.

CALL UFREND ('SQUARE')
1 CONTINUE
CALL UEEND
STOP
END

EXAMPLE XI-3
DATA DEGREE/0.2/
CALL USTART
CALL UPSET ('LIBRARY', 1.)
CALL UWINO (-60., 60., -60., 60.)
CALL UOUTLN
CALL USET ('POLAR')
DO 1 I = 1, 12
   DEGREE = DEGREE + 30.0
   CALL UFRAME ('SQUARE')
   CALL UMOVE (25., DEGREE)

   CALL UFRND ('SQUARE')
1 CONTINUE
CALL UEND
STOP
END
SAMPLE PROGRAM ILLUSTRATING APPLICATIONS OF GCS SUBROUTINES 'USHOW' AND 'UNSHOW'. A SQUARE WILL BE SIMULTANEOUSLY SCALED, ROTATED (ORIENTED), AND TRANSLATED IN NINE DISCRETE PHASES, WITH A SEPARATE FRAME REPRESENTING EACH PHASE.

INITIALIZE VARIABLES, ENTER GCS, AND OUTLINE VIRTUAL WINDOW.

CHARACTER FRAME*8(9)
DATA FRAME/'A', 'B', 'C', 'D', 'E', 'F', 'G', 'H', 'I'/
CALL USTART
CALL UOUTLN
CALL UPSET ('LIBRARY', 1.)

SETUP LOOP TO DEFINE EACH OF THE NINE FRAMES FOR THE SQUARE.

DO 1 I=1,9
   X=10.0*FLOAT(I)

INDICATE THE BEGINNING OF FRAME DEFINITION FOR THE SQUARE, AND PROVIDE COMMANDS TO SCALE, ROTATE, AND TRANSLATE IT.

CALL UFRAME (FRAME(I))
CALL UMOVE X,X)
CALL UPSET ('ROTATE', X)
CALL USET ('RELATIVE')
CALL UPLYGN (0.,0.,4.,FLOAT(I))
CALL USET ('ABSOLUTE')

INDICATE THE TERMINATION OF EACH FRAME, AND CALL UNSHOW TO MAKE THE NEWLY DEFINED FRAME INVISIBLE.

CALL UFREND (FRAME(I))
CALL UNSHOW (FRAME(I))
CONTINUE

AT THIS POINT, ALL OF THE FRAMES HAVE BEEN DEFINED, NOW WE WILL DISPLAY EACH OF THE FRAMES IN SUCCESSION, FOR A TOTAL NUMBER OF 90 CYCLES = 10 OCCURRENCES OF EACH FRAME.

DO 2 I=1,90
   J=MOD((I-1),9)+1

CALL UNSHOW TO DISPLAY THE 'J' TH FRAME (MAKE IT VISIBLE), AND THEN CALL UNSHOW TO MAKE IT INVISIBLE. SINCE THIS IS DONE AT RAPID RATE, THE SQUARE WILL APPEAR TO BE DYNAMICALLY SCALED, ROTATED, AND TRANSLATED.

CALL UNSHOW (FRAME(J))
CALL UNSHOW (FRAME(J))
CONTINUE

INDICATE END OF ALL GRAPHIC ACTIVITY AND TERMINATE PROGRAM.

CALL UEND
STOP
END

APPENDIX A
ALPHABETICAL LISTING OF GCS SUBROUTINES

UAIN  Accepts one character from the terminal
       CALL UAIN (ICHAR)

UALPHA  Insures that terminal is in alphanumeric mode
        CALL UALPHA

UAOUT  Outputs a character at current pen position subject to margining
        CALL UAOUT (ICHAR)

UAPEND  Adds GCS string terminator to character string
        CALL UAPEND (COUNT,DATAIN,DATOUT)

UARC  Draws an arc from current pen position
       CALL UARC (X,Y,ANGLE)

UASPCT  Forces the display dimensions to satisfy the specified aspect ratio
        CALL UASPCT (RATIO)

UAVERG  Fits a moving average curve to time series data
        CALL UAVERG (ARRAY,POINTS,FCST,PERIOD)

UAXIS  Draws axes with appropriate numeric and alphanumeric labeling
        CALL UAXIS (XMIN,XMAX,YMIN,YMAX)

UBAR  Draws a bar chart with appropriate numeric and alphameric labels
       CALL UBAR (ARRAY,PTS,LABELS,SIZE)

UBELL  Sounds the audible alarm at the terminal
       CALL UBELL

UCALL  Invokes a graphic data structure in two dimensions
       CALL UCALL (NAME,DX,DY,SX,SY,ANGLE)

UCHART  Draws a grouped bar chart for multi-valued data
        CALL UCHART (ARRAY,GROUPS,BARS,LABELS,YMAXL)

UCLOSE  Closes the current open frame/segment
        CALL UCLOSE (SEGNAM)

UCOLOR  Defines entries in a program modifiable table of colors
CALL UCOLOR (CLRIDX, CLRCNT, CLRNAM, CLRVAL)

UCONIC  Draws generalized conic sections
        CALL UCONIC (X,Y,P,E,THETA1,THETA2)

UCONTR  Draws contours on regular array of data
        CALL UCONTR (Z,X,Y,A,FX,FY,CURVE,FN)

UCOSYS  Creates a user coordinate plotting system
        CALL UCOSYS (DX,DY,SX,SY,ANGLE)

UCOUNT  Counts number of characters in character string
        CALL UCOUNT (DATA,COUNT)

UCRCLE  Draws a circle whose center location and radius are specified
        CALL UCRCLE (X,Y,RADIUS)

UDAREA  Sets the device display area associated with user window
        CALL UDAREA (XMIN,XMAX,YMIN,YMAX)

UDELAL  Deletes all currently defined frame/segments
        CALL UDELAL

UDELET  Deletes a currently-defined frame/segment
        CALL UDELET (SEGNAM)

UDIMEN  Adjusts physical boundaries of output device (alters aspect ratio)
        CALL UDIMEN (XMAX,YMAX)

UDOIT   Perform various page layout functions
        CALL UDOIT (ACTION)

UDRAW   Draws solid line vector
        CALL UDRAW (X,Y)

UDRIN   Performs the input requested graphic operation and returns request
        CALL UDRIN (X,Y,ICHAR)

UEND    Terminates graphic operations and positions pen in home position
        CALL UEND

UERASE  Erases the screen or requests a clean plotting surface
        CALL UERASE
UERROR  Returns listing of source records with GCS error commentary
         CALL UERROR (ERLAST,TOTAL)

UFLUSH  Insures that visual display reflects all net program graphical output
         CALL UFLUSH

UFONT   Changes the text font
         CALL UFONT (NAMFNT)

UFORMT  Configures the display surface to the requested format
         CALL UFORMT (FORMAT)

UFRAME  Defines the start of a named set of graphical commands
         CALL UFRAME (NAME)

UFREND  Defines the end of a named set of graphical commands
         CALL UFREND (NAME)

UGRIN   Gets coordinates and a character from terminal and returns them
         CALL UGRIN (X,Y,ICHAR)

UHDCPY  Generate a hardcopy
         CALL UHDCPY

UHISTO  Draws a histogram with appropriate numeric and alphanumeric labels
         CALL UHISTO (ARRAY,PTS,BARS)

UHOME   Moves beam to home position
         CALL UHOME

UIMAGE  Applies general 2-D image transformations to 'retained' frames/segments
         CALL UIMAGE (X,Y,SX,SY,R,SEGNAME)

UINPUT  Inputs alphanumeric information from the current position
         CALL INPUT (DATA,COUNT,FLAG,OPTION)

UINVOK  Invokes a GCS structure at the current position
         CALL UINVOK (NAME)

ULINE   Connects two arrays of points with current line option
         CALL ULINE (X,Y,PTS)

ULINFT  Determines linear least squares fit to points provided
         CALL ULINFT (X,Y,XN,S,YI)
ULOOK  Establish portion display area onto which corresponding portion of current virtual space viewport will be mapped
        CALL ULOOK (XMIN,XMAX,YMIN,YMAX)
ULSTSTQ  Calculates least squares polynomial fit to points provided
        CALL ULSTSQ (X,Y,XN,COEFF)
UMARGN  Sets the left and right, top and bottom alphanumeric window boundaries
        CALL UMARGN (XLEFT,XRIGHT,YBOTTM,YTOP)
UMENU   Menu board generating routine
        CALL UMENU (POINTS,LABELS,CHOICE)
UMODFY  Modifies setting of frame/segment attributes
        CALL UMODFY (SEGNAM,NAMAT,ATVALU)
UMOVE   Moves the pen to position specified by input arguments
        CALL UMOVE (X,Y)
UNSSAVE  Renders all variables of the graphic status area
        CALL UNSSAVE (ARRAY)
UNSHOW  Causes the named frame/segment of graphical information to be made invisible
        CALL UNSHOW (NAME)
UNSVPN  Restores all pen related variables in the graphics status area
        CALL UNSVPN (ARRAY)
UNSVTR  Restores coordinate system related variables in the graphics status area
        CALL UNSVTR (ARRAY)
UOPEN    Opens a frame/segment
        CALL UOPEN (SEGNAM,SEGTYP)
UORIGN  Creates a user coordinate system at the current beam/pen position
        CALL UORIGN
UOUTLN  Draws a box around the user's display area
        CALL UOUTLN
UPAUSE  Suspends execution until one character is entered from keyboard
        CALL UPAUSE
UPEN       Draws a line from current pen position to given coordinates
            CALL UPEN (X,Y)

UPEN1      Sets one 'USET' option for this call only before executing pen movement
            CALL UPEN1 (X,Y,OPTION)

UPIE       Draws a pie chart with appropriate numeric and alphabetic labels
            CALL UPIE (ARRAY,PTS,LABELS,SIZE)

UPLACE     Applies 2-D translation image transformation to 'retained' frames/segments
            CALL UPLACE (X,Y,SEGNAME)

UPLLOT     General purpose multi-curve plotting routine
            CALL UPLLOT (X,Y,CURVES,PARRAY,OPTION)

UPLLOT1    Plots a single curve
            CALL UPLLOT1 (X,Y,PTS)

UPLYGN     Draws a regular polygon
            CALL UPLYGN (X,Y,PTSIN,RADIUS)

UPOINT     Defines point which, together with two end points of a given line, defines
            the plane for the terminator and tic line
            CALL UPOINT (X,Y,Z)

UPOST      Insures that only defined, visible frame/segments are displayed
            CALL UPOST

UPRINT     Prints information in hardware or software characters
            CALL UPRINT (X,Y,INPUT)

UPRNT1     Allows alphanumeric output at current position with specified option
            CALL UPRNT1 (DATA,OPTION)

UPSET      Changes setting in the GSA which requires a parameter value to be set
            CALL UPSET (OPTION,VALUE)

UQUERY     Obtains current value of specified variable in GSA
            CALL UQUERY (OPTION,VALUE)

UREAD      Allows alphanumeric input from the graphic terminal
            CALL UREAD (X,Y,DATA,COUNT,FLAG)
URECT  Draws a rectangle
        CALL URECT (X,Y)

UREPRO  Reproduce contents of pseudo-display file on current display device
        CALL UREPRO (FILENR, STATUS)

URESET  Resets GSA variables to default conditions
        CALL URESET

UROTAT  Creates a user coordinate system at current position rotated as specified
        CALL ROTAT (ANGLE)

USAREA  Changes device boundaries to maintain a one to one aspect ratio with the current window boundaries
        CALL USAREA

USAIVE  Saves all the variables of the Graphics Status Area
        CALL USAIVE (ARRAY)

USAXIS  Draws a single axis in any of three coordinates
        CALL USAXIS (AXIS,XSTART,YSTART,ZSTART,DIST)

USCALE  Creates a user coordinate system at current position with specified scale
        CALL USCALE (SX,SY)

USCATR  Draws a scatter plot
        CALL USCATR (X,Y,PTS)

USET    Sets a graphics status area variable to a given value
        CALL USET (OPTION)

USHOW   Causes the named frame/segment of graphical information to be made visible
        CALL USHOW (NAME)

USPLIN  Fits a cubic spline interpolatory curve to the input data
        CALL USPLIN (X,Y,PTS,RETX,RETY,RETPTS)

USTART  Initializes the graphics status area
        CALL USTART

USTRUCT Defines the start of a graphic data structure
        CALL USTRUCT (NAME)
USTUD  Returns limits of two dimensional virtual and display surfaces
       CALL USTUD (ARRAY)

USVPN  Saves all pen-related variables of the graphics status area
       CALL USVPN (ARRAY)

USVTR  Saves coordinate system related variables in the graphics status area
       CALL USVTR (ARRAY)

UTAXIS Draws a time series axis with appropriate alphanemic and numeric labels
       CALL UTAXIS (BEGIN,PERIOD,YMIN,YMAX)

UTERM  Defines the end of a graphic data structure
       CALL UTERM (NAME)

UTILITY Performs data structure utility functions
       CALL UTILITY (OPTION,VALUE)

UTSFIT Fits an exponentially smoothed curve to time series data
       CALL UTSFIT (ARRAY,POINTS,FCST,ALPHA)

UVIEW Defines position of viewer in relation to environment, and the direction of
       view.
       CALL UVIEW (XVIEW,YVIEW,ZVIEW,XSITE,YSITE,ZSITE)

UVWPLN Defines the location of the view (projection) plane
       CALL UVWPLN (DISTAN)

UWAIT  Waits a given number of seconds
       CALL UWAIT (SECONDS)

UWHERE Returns the coordinates of the current pen position in user units
       CALL UWHERE (X,Y)

UWINDO Sets the virtual window boundaries
       CALL UWINDO (XMIN,XMAX,YMIN,YMAX)

UWLOOK Adjusts both virtual window, and user display area to cover given portion
       of virtual space
       CALL UWLOOK (XMIN,YMAX,YMIN,YMAX)

UWRITE Prints information, then restores pen to location on input
       CALL UWRITE (X,Y,DATA)
UWRIT1    Allows alphanumeric output at current position under one option
          CALL UWRIT1 (DATA,OPTION)

UZWNDO    Sets the hither/yon window boundaries for Z-clipping
          CALL UZWNDO (ZMIN,ZMAX)

U3AXIS     Creates a set of axes in 3 space
          CALL U3AXIS (XMIN,XMAX,YMIN,YMAX,ZMIN,ZMAX)

U3CALL     Invokes an existing graphics data structure in 3 space.
          CALL U3CALL (X,Y,Z,SX,SY,SZ,RX,RY,RZ,NAME)

U3CSYS     Creates a new coordinate system in 3 space
          CALL U3CSYS (X,Y,Z,SX,SY,SZ,RX,RY,RZ)

U3DRAW     Draws a solid line in 3-D space
          CALL U3DRAW(X,Y,Z)

U3GRIN     Gets 3-D coordinates and a character from terminal and returns them
          CALL U3GRIN (X,Y,Z,ICHAR)

U3IMAG     Applies general 3-D image transformations to 'retained' frames/segments
          CALL U3IMAG (X,Y,Z,SX,SY,SZ,RX,RY,RZ,SEGNAM)

U3LINE     Connects 3-D arrays of points (X,Y,Z) with current line option
          CALL U3LINE (X,Y,Z,PTS)

U3MOVE     Moves pen invisibly in 3-D space
          CALL U3MOVE (X,Y,Z)

U3PEN      Draws a line from current pen position to given 3-D coordinates
          CALL U3PEN (X,Y,Z)

U3PEN1     Sets one 'USET' option for this call only before executing 3-D pen movement
          CALL U3PEN1(X,Y,Z,OPTION)

U3PLACE    Applies 3-D translation image transformation to 'retained' frames/segments
          CALL U3PLAC(X,Y,Z,SEGNAM)

U3PLOT     Draws a general purpose graph in 3-D space
          CALL U3PLOT (X,Y,Z,CURVES,PTS,OPTS)
U3PRNT Displays textual data at pen position in 3-D space
CALL U3PRNT (X,Y,Z,DATA)

U3ROTA Creates a user coordinate system in three space at current pen position, rotated as specified
CALL U3ROTA (RX,RY,RZ)

U3SCAL Creates a user coordinate system in three space at current pen position, scaled as specified
CALL U3SCAL (SX,SY,SZ)

U3STUD Gives current setting of the 3-D user display area and windows
CALL U3STUD (ARRAY)

U3WHER Returns current pen position in current units in 3-D space
CALL U3WHER (X,Y,Z)

U3WND0 Sets the virtual 3-D window boundaries
CALL U3WND0 (XMIN,XMAX,YMIN,YMAX,ZMIN,ZMAX)

U3WRIT Displays textual information in 3-D space, returns pen to original position
CALL U3WRIT (X,Y,Z,DATA)
APPENDIX B

USET OPTIONS

TABLE 1

USET OPTIONS MOST FREQUENTLY USED

TO REQUEST ABSOLUTE COORDINATE PLOTTING (DEFAULT):

USET ('ABSOLUTE')
USET ('ABSO')
USET ('ABSb')

TO REQUEST RELATIVE OR INCREMENTAL COORDINATE PLOTTING:

USET ('RELATIVE')
USET ('RELA')

TO REQUEST RECTANGULAR COORDINATES (DEFAULT):

USET ('RECTANGULAR')
USET ('RECT')

TO REQUEST POLAR COORDINATES:

USET ('POLAR')
USET ('POLA')

TO REQUEST ANGULAR VALUES IN DEGREES (DEFAULT):

USET ('DEGREES')
USET ('DEGR')

TO REQUEST ANGULAR VALUES IN RADIANS:

USET ('RADIANS')
USET ('RADI')

TO REQUEST PLOTTING IN VIRTUAL SPACE (DEFAULT):

USET ('VIRTUAL')
USET ('VIRT')

TO REQUEST PLOTTING IN DEVICE SPACE:

USET ('DEVICE')
USET ('DEVI')

TO REQUEST DEVICE SPACE PLOTTING UNITS IN INCHES (DEFAULT):

USET ('INCHES')
USET ('INCH')

TO REQUEST DEVICE SPACE PLOTTING IN RASTER UNITS:

USET ('RASTERUNITS')
USET ('RAST')
TO REQUEST DEVICE SPACE PLOTTING IN FONT (CHARACTER SPACE) UNITS:
  USET ('FONTUNITS') USET ('FONT')

TO REQUEST DEVICE SPACE PLOTTING IN PERCENT UNITS:
  USET ('PERCENTUNITS') USET ('PERC')

TO REQUEST PLOTTING OF A VISIBLE LINE (DEFAULT):
  USET ('LINE')

TO REQUEST PLOTTING OF INVISIBLE LINES:
  USET ('MOVE')
  USET ('NOLINE') USET ('NOLI')
  USET ('NOBLINE') USET ('NOBL')

TO REQUEST PLOTTING OF LINES WITH ARROW TERMINATORS:
  USET ('ARROW') USET ('ARRO')

TO REQUEST PLOTTING OF DASHED LINES:
  USET ('DASH')

TO REQUEST PLOTTING OF TIC LINES:
  USET ('TICLINE') USET ('TICL')

TO REQUEST PLOTTING OF LINES WITH ONLY ENDPOINTS VISIBLE:
  USET ('POINT') USET ('POIN')

TO REQUEST PLOTTING OF LINES COMPOSED OF CHARACTERS:
  USET ('ALPHANUMERICLINES') USET ('ALPH')

TO REQUEST PLOTTING OF INVISIBLE LINES WITH CHARACTERS AT THEIR END-POINTS:
  USET ('CHARACTER') USET ('CHAR')

TO REQUEST CHARACTER OUTPUT IN THE FORM OF HARDWARE CHARACTERS (DEFAULT):
  USET ('HARDWARE') USET ('HARD')
TO REQUEST CHARACTER OUTPUT IN THE FORM OF SOFTWARE CHARACTERS:
  \texttt{USET ('SOFTWARE')} \quad \texttt{USET ('SOFT')}

TO REQUEST UPRINT/UWRITE OUTPUT IN TEXT FORMAT (DEFAULT):
  \texttt{USET ('TEXT')}

TO REQUEST UPRINT/UWRITE OUTPUT IN INTEGER FORMAT:
  \texttt{USET ('INTEGER')} \quad \texttt{USET ('INTE')}

TO REQUEST UPRINT/UWRITE OUTPUT IN REAL FORMAT:
  \texttt{USET ('REALNUMBER')} \quad \texttt{USET ('REAL')}

TO REQUEST PLOTTING WITH RESPECT TO THE SYSTEM AXIS (DEFAULT):
  \texttt{USET ('SYSTEM')} \quad \texttt{USET ('SYST')}

TO REQUEST PLOTTING WITH RESPECT TO THE USER AXIS:
  \texttt{USET ('USERAXIS')} \quad \texttt{USET ('USER')}

TO REQUEST A LINE TYPE/CHARACTER TERMINATOR COMBINATION:
  \texttt{USET ('X$bb')} \quad \texttt{USET ('X$')}

Where

$ \text{IS THE DESIRED CHARACTER TERMINATOR}$

\textbf{AND}

$X, \text{ THE LINE TYPE SPECIFICATION, IS AS FOLLOWS:}$

\begin{itemize}
  \item \texttt{A} \enspace \text{ALPHANUMERIC LINE}
  \item \texttt{D} \enspace \text{DASHED LINE}
  \item \texttt{L} \enspace \text{SOLID LINE}
  \item \texttt{N} \enspace \text{NULL OR INVISIBLE LINE}
  \item \texttt{T} \enspace \text{TIC LINE}
  \item \texttt{b} \enspace \text{denotes blank}
\end{itemize}

Dashed lines with character terminators
To select dump option
Echo alphanumeric input option
Immediate error output
Execution of data structure commands as they are built
Data structure editing option
Extended menuing option
Extra large character size
Fast blink rate
Fit linear function to plotted lines
Fit least squares polynomial to plotted points
Fit cubic spline curve to plotted points
Frame identifiers provided as numbers
To indicate device space plotting in font units
Full scaling for higher level graphing
Function key is graphics input device
Alternate light and dark line output
Numeric label output in FORTRAN real (E or F) format
Gothic character font (standard GCS font)
Angular units to be measured in grads
Switch to pen color green
Grid axes for higher level graphing
Output of hardware generated characters
Highlighted segments
Z axis clipping
Alphanumeric output to be printed horizontally
Time series axis scale in twenty-four hourly intervals
Numeric label output in integer format
Ignore duplicate studies on merge file

Coordinates are of the form (R,THETA,PHI) where R is the number of units of radius, THETA is the number of angular units around the Z axis, and PHI is the number of angular units around the X axis.

Menuing option

To specify that the output will be lowered from the specified line of text.

To specify that the output will be raised from the specified line of text.

Error output be suppressed

Invisible lines with character terminators

Plotting on the system axis

Analog tablet as graphic input device

Tic lines with arrow terminators

Tic lines with back arrow terminators

Tic lines with character terminators

Tic lines with endpoint coordinates indicated

Tic lines with double arrow terminators

UPRINT/UWRITE output in text format

Subtractive color blending mode

Tic axes to be drawn for higher level graphing

Tic lines with null terminators

Line width to be thin

Security Classification Top Secret

Tic lines with point terminators

To indicate by an identification number which GCS routine is involved.

Tic lines with character terminators

Time series axis scale in twelve hour intervals

Time series axis scale in twenty four-hour intervals

Security classification unclassified

Disabling pick sensitivity

High level graphing system

Non-gapped line output

Upper case to be 'TEXT' case

Plotting on a user defined axis system

Alphanumeric output to be spaced vertically

View port distance to be measured from the view point

Plotting in virtual space

Visible framed output

Time series axis scale in weekly intervals

Switch to pen color white

Line width to be wide

Plotting on the user's working (temporary axis)

Coordinate system to be the default axis system

To specify the X coordinates with respect to the origin of the current coordinate system for indicated components. Y and Z components are to be specified with respect to the current beam/pen position

The X axis will have an alphanumeric label

The X axis will be drawn for high level graphing

The X axis will have both alphanumeric and numeric labels

**NOTE:** * is a blank or space

* - means not implemented
To indicate that the X component does not vary during the drawing of any curve in higher level graphics.

The X axis at edge of graph.

Logarithmic X and linear Y plotting.

Negative X axis represents up in 3D graphics.

An X axis numeric label.

Positive X axis represents up in 3D graphics.

To specify the X coordinates with respect to the current beam/pen position. Y and Z components are to be specified with respect to the origin of the current coordinate system.

To specify the X coordinates with respect to the current beam/pen position. Y and Z components are to be specified with respect to the origin of the current coordinate system.

To specify the X and Y coordinates with respect to the origin of the current coordinate system for the indicated components. Z components are to be specified with respect to the current beam/pen position.

To specify the X and Y coordinates with respect to the origin of the current coordinate system for the indicated components. Z components are to be specified with respect to the current beam/pen position.

To view the plane formed by the X and Z axes.

To set the rotation application order as indicated.

### APPENDIX C

### UPSET OPTIONS

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'ANGLE OF TEXT'</td>
<td>Is an angular value which specifies the angle of the text string in relation of the current X axis. Default value is 0.</td>
</tr>
<tr>
<td>'ATTENTION QUEUE SIZE'</td>
<td>An integer indicating the number of words provided in the attention queue. Default is 0.</td>
</tr>
<tr>
<td>'ATTITUDE'</td>
<td>Is an angular value which specifies the orientation of the up direction axis with the sides of the window. Default value is 0. Meaning that the up direction is parallel with the left and right window boundaries and pointing towards the top of the window.</td>
</tr>
<tr>
<td>'BACKGROUND COLOR'</td>
<td>Is an integer which specifies the color index within the color table for colored backgrounds. Values 0-7 are predefined to represent black, white, red, green, yellow, blue, magenta, and cyan, respectively. Default color is black or none.</td>
</tr>
<tr>
<td>'BASE OF LOGARITHMS'</td>
<td>Is a positive value which specifies the base of the logarithms used to perform logarithmic scaling or the character string 1HE, denoting the base of the Naperean logarithms. Default base is 10. This option sets the specified base along each coordinate component.</td>
</tr>
<tr>
<td>'BRIGHTNESS'</td>
<td>Is a value between 0 and 100 percent indicating the position in the range of possible line intensity settings from dimmest to brightest. Default brightness is 60%.</td>
</tr>
<tr>
<td>'CHARACTER'</td>
<td>Is a Hollerith character which becomes the current system character. The default system character is a star or asterisk (*).</td>
</tr>
<tr>
<td>'COLOR'</td>
<td>Is an integer which specifies the color index within the color table. Values 0-7 are predefined to represent black, white, red, green, yellow, blue, magenta, and cyan, respectively. Default color is device-dependent.</td>
</tr>
<tr>
<td>'COPY DELAY'</td>
<td>Is a value which indicates the number of seconds of delay required during generation of a hard copy. Default value is device-dependent and is preset to the value required by the selected device.</td>
</tr>
<tr>
<td>'DISTANCE'</td>
<td>Is a value measured from the current view plane distance base specifying the position of the view (projection) plane. The default is 0. measured from the view site.</td>
</tr>
</tbody>
</table>

*means not implemented
'FNT FILE' is a Fortran file number representing the file containing the font descriptors. Default is zero indicating no font file specified.

'FONT NAME' is a Hollerith string indicating the desired character font. Default is 'GCS' which is the most efficient font.

'GREYSCALE' is a value indicating a particular grey level for terminals which support multiple grey scales rather than colors.

'GRID SPECIFICATION' is a value containing a dash specification to be used when generating grid axes. Default is 0, which indicates a solid line should be used.

'HORIZONTAL SIZE' indicates the width of a software character position in current user units. Default is 5 virtual units.

'INPUT FILE' is a Fortran file number indicating which file will be used to obtain graphics input. The default is set to the appropriate computer-system dependent file.

'LABELbROTATION' is the number of angular units the axes labels are to be rotated around the axes.

'LIBRARY FILE' is a Fortran file number indicating which file should be used by the GCS structure and segmentation facilities as a random work file. Default is 0, indicating no file has been provided.

'LOWER' is a Hollerith character which will be used by GCS as the indication to shift to lower case. Default character is '>'.

'MARKER INDEX' is an integer value selecting a marker/symbol. Default marker symbol is 0, indicating a point.

'ORIENTATION' is an angular value indicating the display orientation of GCS created software symbols and figures such as software characters, polygons, and rectangles. Default orientation is 0.

'OUTPUT FILE' is a Fortran file number indicating which file will be used for sending graphics output to the display device. The default is set to the appropriate computer-system dependent file.

'POLYNOMIAL DEGREE' specifies the degree of the polynomial to be created in calculating a least squares fit through a collection of points. Default value is 5.

'PRECISION' specifies the number of significant digits to appear when displaying real numbers. Default value is 4.

*means not implemented
'READFILE'  
Is a Fortran file number indicating which file will be used to obtain non-graphic input. The default is set to the appropriate computer system dependent file.

'ROTATION'  
Same as 'ORIENTATION'.

'SCALEFACTOR'  
Specifies a scale to be applied to GCS-created geometric figures such as polygons and rectangles.

'SCRIPTLEVEL'  
Is an integer value indicating the scripting level to be set for textual output. Default value is 1.

'SETDASH'  
Specifies the characteristics of the dashed lines to be plotted by UPEN. Default value is 56.

'SIZE'  
Is a positive integer value which sets hardware character sizes. Values of 1 through 4 correspond to USET options 'SMALL', 'MEDIUM', 'LARGE', and 'EXTRA LARGE' respectively. Default value is 1 for 'SMALL' characters.

'SLANTANGLE'  
Is an angular value indicating the amount of slant from the vertical for italicized software characters. Default value is approximately 18 degrees.

'SPAN ANGLE'  
Is an angular value indicating the portion of a circle to be occupied by the pie chart. Default value is 360 degrees.

'SPECIFICATION UNITS'  
Is a positive value indicating the number of specification units contained in device space for all directions. Default value is 1000.

'SPEED'  
Specifies the speed of the communication line in characters per second. Default value is system dependent.

'START ANGLE'  
Is an angular value indicating the starting position of the first wedge of the pie chart. Default value is 0.

'STRUCTURE TABLE SIZE'  
Is an integer value indicating the number of words in the user provided structure table. Default value is 100.

'SUBSCRIPT CHARACTER'  
Is a Hollerith character which will be used to decrease the scripting level by 1. Default subscript character is 'the display code is a pound sign'.

'SUPERSCRIPT CHARACTER'  
Is a Hollerith character which will be used to increase the scripting level by 1. Default superscript character is 'the display code is an underline sign'.

'*' means not implemented
'SZMARKER'

Is a value in current device units which specifies the size of software generated markers. Default value is device-dependent.

'TABHORIZONTAL'

Is an array of 10 elements containing 10 tab positions in current device units. Default value has all tab stops set to zero.

'TABVERTICAL'

Is an array of 10 elements containing 10 vertical tab positions in current device units. Default value has all tab stops set to zero.

'TERMINATOR'

Is a Hollerith character which will be used as the GCS string terminator character. Default character is a backslash.

'TICINTERVAL'

Specifies the distance in current user units between tic marks of a UPEN created tic line. Default value is 10.

'TICLENGTH'

Specifies in current units the size of that portion of a tic mark which lies on the clockwise side of the tic line. Default value is .05 inches.

'TICPLUS'

Specifies in current units the size of that portion of a tic mark which lies on the clockwise side of the tic line. Default value is .05 inches.

'TICX'

Specifies the distance between tic marks or grid lines along X axes. Default value is 0, indicating that a 'nice' number should be chosen.

'TICY'

Is the same as 'TICX' for Y axes.

'TICZ'

Is the same as 'TICX' for Z axes.

'UPPER'

Is a Hollerith character which will be used by GCS as the indication to shift to upper case. Default character is '<'.

'VERTICAL SIZE'

Indicate the height of a software character position in current user units. Default value is seven virtual units.

'WIDTH'

Is a value in current units of the width of a line. Default value is 0, indicating a thin line.

'WRITE FILE'

Is a Fortran file number indicating which file will be used to generate non-graphic output. The default is set to the appropriate computer system dependent file.

'XBASE OF LOGS'

Is a positive value which specifies the base for logarithmic scaling along the X component. Default value is 10.

'XLABEL'

Specifies the alphanumeric label to be displayed along X axes. Default value is 'X'.

* means not implemented
'XPERCENT'

Is a value specifying the portion of the width of a software character position to be occupied by a character. Default value is .65 indicating 65% of the width.

'XROTATION'

Is an angular value indicating the amount of rotation around the X axis for UNIVOK structure invocations. Default value is 0.

'XSCLAE'

Is the scale factor to be applied along the X axis for UNIVOK structure invocations. Default value is 1.

'XSIZE'

Is the size of hardware or simulated hardware character positions in current device units. Default value is device-dependent and corresponds to 'SMALL' hardware character size.

'XSPECIFICATION UNITS'

Is a positive value indicating the number of X specification units in device space. Default value is 1000.

'YBASE OF LOGS'

Is a positive value indicating the number of X specification units in device space. Default value is 1000.

'YBASE OF LOGS'

Is a positive value which specifies the base for logarithmic scaling along the Y component. Default value is 10.

'YLABEL'

Specifies the alphanumeric label to be displayed along the Y axis. Default value is 'Y'.

'YPERCENT'

Is a value specifying the portion of the height of a software character position to be occupied by a character. Default value is .65 indicating 65% of the height.

'YROTATION'

Is an angular value indicating the amount of rotation around the Y axis for UNIVOK structure invocations. Default value is 0.

'YSCALE'

Is the scale factor to be applied along the Y axis for UNIVOK structure invocations. Default value is 1.

'YSIZE'

Is the size of hardware or simulated hardware character positions in current device units. Default value is device-dependent and corresponds to 'SMALL' hardware character size.

'YSPECIFICATION UNITS'

Is a positive value indicating the number of Y specification units in device space. Default value is 1000.

'ZBASE OF LOGS'

Is a positive value which specifies the base for logarithmic scaling along the Z component. Default value is 10.

*means not implemented
'ZLABEL'

Specifies the alphanumeric label to be displayed along the Z axis. Default value is 'Z '.

'ZROTATION'

Is an angular value indicating the amount of rotation around the Z axis for UINVOK structure invocations. Default value is 0.

'ZSCALE'

Is the scale factor to be applied along the Z axis for UINVOK structure invocations. Default value is 1.

*means not implemented
This appendix addresses those options which are present in the Graphics Status Area as default options. After a call to Subroutine USTART, the Graphics Compatibility System is set to the default conditions, as indicated. The default options can be divided into two groups: Basic Plotting Options and High Level Plotting Options.

I. Default Basic Plotting Options

Plotting is done in ‘RECTANGULAR’ and ‘ABSOLUTE’ coordinates on the ‘SYSTEM’ coordinate axis. The ‘USER’ coordinate axes are identical to the system axis. Plotting is done in ‘VIRTUAL’ space with a virtual window whose limits are from 0.0 to 100.0 in the X direction, and from 0.0 to 100.0 in the Y direction. The virtual window is mapped into a display area which is the largest square area on the device display surface. The right hand edge of the square corresponds to the right edge of the display surface, and the top edge of the square corresponds to the top edge of the display surface.

Character output in GCS will be, by default, in ‘HARDWARE’ character format, of type ‘GOTHIC’ and of ‘MEDIUM’ size. If ‘SOFTWARE’ characters are requested via USET then the default horizontal size is five (5.0) virtual units, and the default vertical size is seven (7.0) virtual units.

By default, angular units for angular specifications are in ‘DEGREES’. If the user switches to ‘DEVICE’ space, then all length or distance units (i.e. rectangular coordinates) are in terms of ‘INCHES’. The default alphanumeric margins are the boundaries of the plotting surface. For alphanumeric I/O through GCS (i.e. from UPRINT or UREAD), the data will be assumed to be in ‘TEXT’ mode. The alphanumeric output defaults to the ‘PLOT’ device if possible, and any graphic output will go to all devices in a cluster. Graphic input is from the primary input device; the number of digits of precision for numeric output is four (4); and GCS detected errors are signalled as they occur.

A line which is drawn by a subroutine in GCS is considered to consist of two parts; a line type and a line terminator. The line type may be solid (visible), ticked, null (invisible), dashed, or alphanumeric. The line may be terminated by an arrow, a back arrow, double arrows, a character, a point, a symbol, a set of coordinate values, or nothing at all. The default line type in GCS is ‘SOLID’ with ‘NULL’ terminators (‘LNULL’). If ‘TICLINES’ are requested via USET option, then the default tic interval is ten (10.0) virtual units. It is the user’s responsibility to insure that the tic interval is appropriate if he switches to ‘DEVICE’ space or alters the default virtual window setting or the default display area setting. If ‘DASHLINES’ are requested, then the default dash specification (56.) will result in a dashed line which is alternately light and dark, in increments of approximately 0.075 inches. If a ‘CHARACTER’ line terminator is requested but no character is specified by way of Subroutine UPSET, then the character asterisk (*) is used. Similarly, the asterisk is used to compose the line type if ‘ALPHANUMERIC’ lines are requested.

For 3D operations, the viewing environment is set up to simulate a 2D only environment. The view point is located at (0.,0.,150.), the view site is at (0.,0.,0.) and the view plane is located at the view site. The system coordinate system is considered to be ‘RIGHT-HANDED’ with the ‘ZPOSITIVEAXIS’ representing up. Note that since the view is down the Z axis, the up direction degenerates to ‘YPOSITIVE’. The Z axis clipping planes are 150. (hither plane) and 1.0E+30 (yon plane) with ‘NOZCLIPPING’.
II. Default High Level Plotting Options

For each call to UPL0T or UPL0T1, the data values which represent the curves are examined, and a 'NEWSCALE' is created. UAXIS will be invoked to create 'XYAXES'. The data values will be examined, appropriate limits for the established. Numeric labels only will be output for the X axis and the Y axis. The axes will be positioned at the 'EDGE' of the plot. Both the X axis and the Y axis will be drawn in a linear coordinate space. The axis lines will be ticked. If a time series axis is plotted by invoking Subroutine UTAXIS, the default interval for the X axis will be 'DATE'. No curves will be fit to the data values, but if 'FITPOLYNOMIAL' is requested, then subroutine UPL0T will attempt to fit a fifth degree polynomial to the data.

III. Summary

COORDINATE SPACE: 'VIRTUAL'
COORDINATE TYPE: 'ABSOLUTE'
COORDINATE SYSTEM: 'RECTANGULAR'
COORDINATE AXIS: 'SYSTEM'

VIRTUAL WINDOW: 0.0 TO 100.0 X DIRECTION
                 0.0 TO 100.0 Y DIRECTION

DISPLAY AREA: Largest square area which is right-up on the display surface of the device.

DEVICE SPACE UNITS: 'INCHES'
ANGULAR UNITS: 'DEGREES'

LINE TYPE: 'LINE' or 'LNULL'
SYSTEM CHARACTER: asterisk (*)
TIC INTERVAL: 10.0 virtual units
DASH SPECIFICATION: 56.

CHARACTER TYPE: 'HARDWARE'
CHARACTER FONT: 'GOTHIC'
CHARACTER SIZE: 5.0 virtual units horizontal
                7.0 virtual units vertical

SOFTWARE CHARACTER SIZE:
INPUT/OUTPUT FORMAT: 'TEXT'
ALPHANUMERIC MARGINS: Device display surface boundaries.
OUTPUT ROUTE: 'PLOTDEVICE'
OUTPUT DISTRIBUTION: 'ALLDEVICES'
GRAPHIC INPUT: Primary input device

DIGITS OF PRECISION: 4
ERROR HANDLING: 'IMMEDIATE OUTPUT'

AXIS SCALING: 'AUTOSCALE'
AXIS LABELING: 'XNUMERICLABEL'
              'YNUMERICLABEL'
AXIS POSITIONING: 'EDGEAXIS'
AXIS TYPE: 'TICAXIS'
AXIS EXISTENCE: 'XYAXES'
AXIS COORDINATES: 'NOLOGARITHMS'

TIME SERIES AXIS SCALE: 'DATE'
Lines that are drawn by GCS are composed on a line type and a line terminator. A large number of line types and terminators are possible. The specification is composed by
combining the first letter of the line type with the name of the terminator. The following tables illustrate the possible linetypes and terminators:

<table>
<thead>
<tr>
<th>LINE TYPE</th>
<th>FIRST LETTER</th>
</tr>
</thead>
<tbody>
<tr>

APPENDIX G

GCS ERROR CODES

The following is a list of the currently defined error codes in GCS:

01 — Invalid key word specification to USET.
02 — Invalid key word specification to UPSET.
03 — No plot files found.
04 — Invalid option for UPRNT1.
05 — Invalid UDOIT system.
06 — Invalid view port boundaries.
07 — UFORMT — Invalid Display Surface Format.
08 — Invoke font specification.
09 — Invalid UINPUT option.
10 — UMARGN argument list out of order/Boundary specification invalid.
11 — UMARGN boundary outside of physical device boundary.
12 — UWINDO argument list out of order/Boundary specifications invalid.
13 — UDAREA argument list out of order/Boundary specifications invalid.
14 — UDAREA boundary outside of physical device boundary.
15 — UCLIP invalid argument list.
16 — UCLIP boundary overlap error.
17 — UDIMEN maximum boundary specification invalid.
18 — UAXIS argument list XMIN.GT.XMAX and/or YMIN.GT.YMAX.
19 — UDAREA provided to UAXIS too small for requested options.
20 — UPSET — invalid tic interval. Value LE.zero specified.
21 — UPSET — invalid scale factor. Value must not be equal to zero.
22 — UPSET — invalid software character size. Value must not be equal to zero.
23 — UPSET — invalid digits of precision. Precision must be greater than zero.
24 — UPSET — attempt to set zero or negative scripting — level.
25 — UPSET — invalid light pen correlation value. Value must be GT.zero.
26 — UPSET — invalid transmission speed. Value must be .GT.zero.
27 — UPSET — Invalid Library file code. File codes must be in range 1 to 99.
28 — UPSET — Invalid error limit. Value must be greater than zero.
29 — UPSET — Invalid error limit. Value must be greater than zero.
30 — UFRAME/UFREND frame table full.
31 — Failure to call UFREND for previous occurrence of same frame.
32 — Failure to call UFREND for another named frame.
33 — UFREND called without any frame active.
34 — UFREND call not for currently active frame.
35 — USHOW/UNSHOW called for undefined frame.
36 — USHOW/UNSHOW called while in frame build status.
50 — PLOT — Constant or delta X or Y values illegal for automatic curve fitting.
51 — Insufficient data points for desired fit.
52 — Input data points exceed fit capacity.
53 — Input data out of order or non functional relationship.
54 — Insufficient array space to return fitted results.
55 — Invalid trend adjustment factor.
56 — Invalid polynomial degree for polynomial fit.
57 — Invalid number of previous periods for moving average fit.
60 — Attempt to build a structure in frame mode.
61 — Nested structure call stack overflow.
64 — Attempt to redefine existing structure.
65 — Structure table overflow.
66 — Attempt to activate a structure while another is still active.
67 — Structure termination without active structure.
68 — Structure termination not for current structure.
69 — Attempt to execute an undefined structure.
70 — Recursive structure build call.
71 — Invalid number of items for UREAD/UIINPUT.
72 — Attempted input operation from batch device.
80 — Attempt to create a secondary axis scale of zero.
81 — UAXIS — pen position outside of UDAREA in ‘PENAXES’.
82 — Attempt to plot log with window bound .LE. 0.0
83 — Attempt to move to apply log scaling to coordinate whose value is zero.
84 — Log plotting in device space not allowed.
85 — UAXIS — AXIS choice requires 0 to 1 within range of X and/or Y AXIS.
86 — ULINE/U3LINE — Invalid number of points.
91 — UAPEND found zero length string. Terminator placed in first character position.
92 — UWAIT — Negative time period specified.
93 — UQUERY — Invalid option specification.
94 — UCOLOR — Invalid color index.
95 — UCOLOR — Duplicate color component.
96 — UCOLOR — Duplicate color component.
97 — UCOLOR — Invalid color name.
98 — UCOLOR — Invalid color component value.
99 — UCOLOR — Colinear with line.
101 — UHISTO — Insufficient points.
102 — UHISTO — Invalid number of bars.
103 — UHISTO — Unreasonable window for OWNSCALE.
104 — UHISTO — Insufficient UDAREA for options specified.
110 — Invalid number of points for UPIE.
111 — Invalid data value for UPIE.
112 — Invalid max label size for UPIE.
113 — Insufficient room for UPIE display.
114 — UPIE — ABS(Starting Angle > = ABS(Ending Angle).
115 — UPIE — Too many labels outside of pie.
120 — USCATR — Insufficient points specified.
121 — USCATR — Invalid limits for logarithmic scatter diagram.
122 — USCATR — UDAREA too small for specified options.
130 — UBAR — Invalid number of points.
131 — UBAR — Invalid label size.
132 — UBAR — Invalid data value.
133 — UBAR — Insufficient UDAREA for options specified.
140 — UCHART — Invalid number of points.
141 — UCHART — Invalid label size.
142 — UCHART — Invalid number of bars.
143 — UCHART — UDAREA too small for specified options.
150 — UTAXIS — UDAREA too small for specified options.
160 — UTILITY — Invalid action.
161 — UTILITY — Save structure not found.
162 — UTILITY — Utility operation on structure work file.
164 — UREPRO — Invalid pseudo-device file number.
165 — UREPRO — Invalid pseudo-device file format.
166 — UREPRO — Read error on pseudo-device file.
167 — UREPRO — Invalid pseudo-device command.
168 — UREPRO — End-of-file within pseudo-device command.
169 — UREPRO — Open segment of UREPRO invocation.
190 — UVIEW — Viewpoint specified same as view site.
191 — UVWPRT — Aperature specified negative or zero in some dimension.
192 — UVWPRT — Viewport behind viewer.
193 — Attempt to draw through viewpoint.
194 — Hither plane behind or at viewpoint.
In accordance with letter from DAEN-RDC, DAEN-ASI dated 22 July 1977, Subject: Facsimile Catalog Cards for Laboratory Technical Publications, a facsimile catalog card in Library of Congress MARC format is reproduced below.

Westinghouse Word Processing Center, Pittsburgh.
Primer on computer graphics programming / by Westinghouse Word Processing Center, Pittsburgh, Pa. Vicksburg, Miss.: U. S. Waterways Experiment Station; Springfield, Va.: available from National Technical Information Service, 1979. v, [201] p. : ill. ; 27 cm. (Miscellaneous paper - U. S. Army Engineer Waterways Experiment Station ; 0-79-4)
