Approved for public release; distribution unlimited.
ABSTRACT

During the period covered by this report we continued our research on the development and application of numerical methods for singularly-perturbed (or stiff) boundary value problems for ordinary differential equations and initial-boundary value problems for partial differential equations. Results were obtained for collocation methods for vector systems of two-point boundary value problems and for adaptive grid finite element methods for partial differential equations. We are applying our methods to several interesting physical problems, such as, the deformation of nonlinear elastic beams and a nonlinear Schrödinger equation which exhibits self focusing.

During the period covered by this report we continued our research on the development and application of numerical methods for singularly-perturbed ordinary and partial differential equations.

1.1 Boundary Value Problems for Ordinary Differential Equations

Our work on combined asymptotic and numerical (collocation) techniques for vector systems of boundary value problems is continuing and it will appear in a sequence of two papers [4,5]. A third paper [7] on the subject is being prepared for the proceedings of the Tenth IMACS World Conference, which will be held in Montreal this August, and a fourth paper [8] will be submitted to SIAM Journal of Scientific and Statistical Computing later this year. All of these papers are joint research between Professors J. E. Flaherty and R. E. O'Malley, Jr. Professor O'Malley joined R.P.I. as Chairman of the Department of Mathematical Sciences in June 1981.

We have applied our methods to some interesting and challenging nonlinear singularly-perturbed problems and have found them to be both efficient and accurate. One area where our methods seem to be very successful is in studying the deformation of nonlinear elastic beams (cf. [4]).

Flaherty, O'Malley, and G. M. Heitker, a graduate student under their direction, have recently begun studying collocation and difference methods for vector systems of boundary value problems that have potential for turning point problems. In the spirit of our earlier work on scalar equations**, these methods have the advantage of only needing a fine discretization in

*See the list of Publications and Abstracts at the end of this report.

boundary layer regions for accuracy and not for stability. Thus, we can create an algorithm that starts with a relatively coarse discretization to obtain a stable solution and then adaptively refines the grid within boundary layer regions for greater accuracy.

1.2. Initial-Boundary Value Problems for Partial Differential Equations

A paper [1] describing our adaptive grid finite element procedure for initial-boundary value problems for vector systems of partial differential equations has appeared in the SIAM Journal on Scientific and Statistical Computing. This work was based on the Ph.D. Dissertation of S. F. Davis who was a graduate scholar under the direction of Professor Flaherty and who was supported by this grant.

Flaherty and a graduate student, J. M. Coyle, have added several improvements to our adaptive finite element code. These include time step refinement routines and the ability to add or delete elements. They have also begun work on a two-dimensional version of the code.

Flaherty, Coyle, and A. C. Newell of the University of Arizona have been applying our adaptive finite element code to a focusing problem for a nonlinear Schrodinger equation [9]. This problem describes the focusing of a laser beam in a medium with a nonlinear index of refraction. It is a difficult numerical problem because the amplitude of the solution becomes infinite as focusing occurs; however, our adaptive code seems to be able to cope with this and is providing very good results.

Our work on using splines in tension to construct explicit finite difference and finite element schemes for hyperbolic and parabolic systems of partial differential equations has appeared in the Transactions of the Twenty-Seventh Conference of Army Mathematicians [2]. A second note on this subject

Flaherty and T. Jackson, a graduate student, have recently begun working on constructing implicit discontinuous finite element methods for hyperbolic systems. The discontinuous finite elements appear to be giving very sharp shocks, with no spurious oscillations or diffusion and without the need to explicitly track the shocks.

This grant provides funds for a visitor, and this year we invited David Gottlieb of ICASE, NASA Langley Research Center, to R.P.I. He gave a lecture on pseudo-spectral methods for hyperbolic problems with shock waves. We also held several informal discussions on problems of mutual interest.

2. Interactions

Professor Flaherty was invited to lecture on material pertaining to this grant at the following conferences or organizations:

Twenty-Seventh Conference of Army Mathematicians, USMA, West Point, 10–12 June, 1981.

Courant Institute of Mathematical Sciences, New York University, 11 December, 1981.

Program in Applied Mathematics, University of Arizona, Tucson, AZ (gave a series of lectures on adaptive methods for partial differential equations).
Professor Flaherty visited the following laboratories and organizations and conducted or discussed research on the topics noted:

Benet Weapons Laboratory, Watervliet Arsenal, Watervliet, New York, one day per week. Conducted research on adaptive grid and exponentially weighted finite element methods. Applied these methods to wave propagation, impact, and penetration problems.

Organized with Jagdish Chandra of the U. S. Army Research Office the "ARO Workshop on Computational Aspects of Penetration Mechanics", held 27-29 April, 1982 at Aberdeen Proving Ground, MD.

AN ADAPTIVE FINITE ELEMENT METHOD FOR INITIAL-BOUNDARY VALUE PROBLEMS FOR PARTIAL DIFFERENTIAL EQUATIONS

Stephen F. Davis
Rensselaer Polytechnic Institute

and

Joseph E. Flaherty

Institute for Computer Applications
in Science and Engineering

ABSTRACT

A finite element method is developed to solve initial-boundary value problems for vector systems of partial differential equations in one space dimension and time. The method automatically adapts the computational mesh as the solution progresses in time and is thus able to follow and resolve relatively sharp transitions such as mild boundary layers, shock layers, or wave fronts. This permits an accurate solution to be calculated with fewer mesh points than would be necessary with a uniform mesh.

The overall method contains two parts, a solution algorithm and a mesh selection algorithm. The solution algorithm is a finite element-Galerkin method on trapezoidal space-time elements, using either piecewise linear or cubic polynomial approximations and the mesh selection algorithm builds upon similar work for variable knot spline interpolation.

A computer code implementing these algorithms has been written and applied to a number of problems. These computations confirm that the theoretical error estimates are attained and demonstrate the utility of variable mesh methods for partial differential equations.

Explicit Difference Schemes for Wave Propagation and Impact Problems

Joseph E. Flaherty

Rensselaer Polytechnic Institute
Troy, New York 12181

and

U.S. Army Armament Research and Development Command
Large Caliber Weapons Systems Laboratory
Benet Weapons Laboratory
Watervliet, New York 12189

Abstract

Explicit finite difference and finite element schemes are constructed to solve propagation, shock, and impact problems. The schemes are of upwind difference type, but suffer less from the effects of numerical dispersion and diffusion than classical upwind schemes. The relationship of the new schemes to existing explicit schemes is analyzed and numerical results and comparisons are presented for several examples.

ABSTRACT

A rational function is presented for approximating the function $f(z) = \coth z - 1/z$ that appears in several exponentially fitted or weighted finite difference and finite element methods for convection-diffusion problems. The approximation is less expensive to evaluate than $f(z)$ and provides greater accuracy than the doubly asymptotic approximation when $z = O(1)$.

SINGULARLY PERTURBED BOUNDARY VALUE PROBLEMS
FOR NONLINEAR SYSTEMS, INCLUDING A CHALLENGING PROBLEM
FOR A NONLINEAR BEAM

by

Joseph E. Flaherty

and

Robert E. O'Malley, Jr.
Department of Mathematical Sciences
Rensselaer Polytechnic Institute
Troy, New York 12181 USA

ABSTRACT

We consider certain singularly perturbed two-point boundary value problems involving nonlinear vector systems

\[ \dot{x} = f(x,y,t,\varepsilon), \quad \varepsilon y = g(x,y,t,\varepsilon) \]

of \( m + n \) ordinary differential equations on a finite interval \( 0 < t < 1 \) subject to \( q \) initial conditions and \( r \) terminal conditions of the form

\[ A(x(0),y(0),\varepsilon) = 0, \quad B(x(1),y(1),\varepsilon) = 0, \]

with \( q + r = m + n \). Most critically, in addition to natural smoothness assumptions, we assume that the \( n \times n \) Jacobian matrix \( g_y(x,y,t,0) \) has a hyperbolic splitting with \( k > 0 \) stable eigenvalues (i.e., eigenvalues having strictly negative real parts) and \( n - k > 0 \) (strictly) unstable eigenvalues for all \( x \) and \( y \) and \( 0 < t < 1 \). We suppose that \( q > k \) and \( r > n - k \) and we find limiting solutions as the small positive parameter \( \varepsilon \) tends to zero.

We apply our asymptotic methods to study the deformation and stresses in a thin nonlinear elastic beam resting on a nonlinear elastic foundation. Results are presented for simple, clamped, and elastic support conditions.

ASYMPTOTIC AND NUMERICAL METHODS FOR VECTOR SYSTEMS

OF SINGULARLY-PERTURBED BOUNDARY VALUE PROBLEMS

ABSTRACT

Procedures are developed for constructing asymptotic solutions for certain nonlinear singularly-perturbed vector two-point boundary value problems having boundary layers at one or both end points. The asymptotic approximations are generated numerically and can either be used as is or to furnish a two-point boundary value code (e.g. COLSYS) with an initial approximation and a nonuniform computational mesh. The procedures are applied to several examples involving the deformation of nonlinear elastic beams.

NEW HIGHER-ORDER BOUNDARY-LAYER EQUATIONS
FOR LAMINAR AND TURBULENT FLOW PAST AXISYMMETRIC BODIES

C. KLEINSTREUER, A. EGHIMA AND J. E. FLAHERTY
Rensselaer Polytechnic Institute
Troy, New York 2181

ABSTRACT

New sets of boundary-layer equations accounting for flow field non-uniformities such as curvature effects, normal stress and pressure variations as well as separation, are derived. The boundary-layer flow domain is subdivided into (1) a parabolic region where the fluid flow is approximately parallel to the submerged body, i.e. \( v \ll u \) and (2) an elliptic region which includes the line of separation where significant interactions between the boundary-layer and the outer potential flow occur, i.e. \( v = u \). Closure for the turbulent flow equations has to be obtained with submodels for the Reynolds stresses which reflect the effects of boundary-layer thickening as well as separation. The accuracy of the parabolic equations was compared with Van Dyke's higher-order boundary-layer equations for laminar flow past a body with longitudinal curvature. The results demonstrate that the new modeling equations make a measurable difference as expected from observations made by Bradshaw and others.

ON THE NUMERICAL SOLUTION OF SINGULARLY-PERTURBED VECTOR
BOUNDARY VALUE PROBLEMS

by
Robert E. O'Malley, Jr.

and

Joseph E. Flaherty
Department of Mathematical Sciences
Rensselaer Polytechnic Institute
Troy, New York 12181 USA

ABSTRACT

Numerical procedures are developed for constructing asymptotic solutions
of certain nonlinear singularly-perturbed vector two-point boundary value
problems having boundary layers at one or both end points. The asymptotic
approximations are generated numerically and can either be used as is or to
furnish a two-point boundary value code (e.g. COLSYS) with an initial approx-
imation and a nonuniform computational mesh. The procedures are applied to a
model problem that indicates the possibility of multiple solutions and
problems involving the deformation of a thin nonlinear elastic beam resting on
a nonlinear elastic foundation.

NUMERICAL METHODS FOR STIFF SYSTEMS OF
TWO-POINT BOUNDARY VALUE PROBLEMS

Robert E. O'Malley, Jr.

and

Joseph E. Flaherty
Department of Mathematical Sciences
Rensselaer Polytechnic Institute
Troy, New York 12181 USA

ABSTRACT

We develop collocation methods for a class of singularly-perturbed two-point boundary value problems where the critical Jacobian has a hyperbolic splitting with a fixed number of stable and unstable eigenvalues. We use the asymptotic representation of the solution and a collocation method to construct an approximate solution. This solution can either be accepted or supplied as an initial guess to a two-point boundary value code, such as COLSYS, for further refinement. Our methods are applied to several nonlinear problems.

FOCUSING PROBLEMS FOR A NONLINEAR SCHRODINGER EQUATION

J. M. Coyle
and
Joseph E. Flaherty
Department of Mathematical Sciences
Rensselaer Polytechnic Institute
Troy, New York 12181 USA

and
Alan C. Newell
Program in Applied Mathematics
University of Arizona
Tucson, AZ 85721

ABSTRACT

We consider a cylindrically symmetric Schrodinger equation with a cubic nonlinearity. It is known that this equation has solutions that self-focus if the initial data is strong enough. We study this problem numerically using a self-adaptive finite element code and seek to determine (i) the quantitative nature of the solution as it focuses and (ii) whether the solution will still focus in the presence of a small amount of dissipation.
