**Title:** The Orientation Distribution on Nonspherical Aerosol.

**Author:** Isaiah Gallily

**Performing Organization:** Hebrew University of Jerusalem

**Contract or Grant Number:** DAJA45-83-C-0004

**Program Element, Project, Task Area & Work Unit Numbers:** 61102A-ITT61102-BH57-01

**DISTRIBUTION STATEMENT (of this Report):** Approved for public release; distribution unlimited.

**ABSTRACT:** The orientation distribution function of fibrous and platelet-like aerosol particles was calculated for a general laminar flow by solving the Fokker-Plank equation. It has been found that this function shows maxima and minima, which indicates a preferred orientation. The cases of a point source and a laminar jet are brought out as an example.

**KEY WORDS:** Aerosols; Nonspherical aerosols; Orientation; Distribution; Fibrous aerosols; Platelet aerosols.
General

The orientation distribution function $F$ of nonspherical aerosol particles is very decisive for many cloud properties such as light scattering and radiative transfer (1,2), diffusional transport mechanics (3-5) and average rate of sedimentation (6).

It is also very important in rheology for the constitutive properties of non-Newtonian fluids (7-9).

In general, the orientation function is affected by two opposing physical factors: The randomizing action of the rotational Brownian motion (or micro-turbulent eddies) and the orienting influence of flow gradient.

Up to now, the studied situations were those of the (asymptotic) weak and strong field in which the rotational Peclét number $\alpha$, which indicates the ratio between the above factors, viz. $\alpha = \frac{W^*}{D}$ was $\alpha \ll 1$ or $\alpha \gg 1$. Likewise, the investigations were rather concerned with the simple shear flows.

Aim of Study

Since many cases of significance are characterized by values of $\alpha$ of the order of unity, as occurs in the free atmosphere and with typically-sized particles, it became of interest to study these cases. In addition, the general laminar field where the nine components of the gradient tensor had to be treated once for its own significance and second time for employing it in models for the real, turbulent atmosphere.

Basic equations and assumptions

The basic equation in the reported study was the (source-free) Fokker-Planck equation of conservation in angle-space

$$\frac{\partial F}{\partial t} + \nabla \cdot (F \nabla - D \cdot \nabla F) = 0 \quad [1]$$

For nomenclature see Appendix
We have considered a system of small spheroidal particles immersed in a general laminar flow which is given in their vicinity by the linear relationship.

\[ \mathbf{u}(\mathbf{x},t) = \mathbf{W}(t) \cdot \mathbf{x} \quad [2] \]

The small particles simulate (asymptotically) straight long fibers or flat platelets which are used in many applications. The rotational velocity of the particles \( \omega \) of Eq.[1] was taken to be given by the Jeffery's equation (10)

\[ \omega_i = \frac{1}{2} \left[ \mathbf{V}_{i, j} \mathbf{k}_j + S_{k, j} \mathbf{a}_j \mathbf{a}_k \left( \mathbf{a}_j \cdot \mathbf{a}_k \right) \right] \quad [3] \]

where \( i, j, k \to 1, 2, 3 \) are cyclic permutation indices, \( \mathbf{a}_i, \mathbf{a}_j, \mathbf{a}_k \) are the semi-axes of the ellipsoids, \( \mathbf{V}_{i, j} = \mathbf{W}_{i, j} - \mathbf{W}_{i, j} ; S_{k, j} = \mathbf{W}_{i, j} + \mathbf{W}_{j, i} \); \( \mathbf{W}_{i, j} = \partial \mathbf{u} / \partial x_j \) and \( \mathbf{u}'(\mathbf{x},t), \mathbf{x} \) are respectively the (fluid) velocities and location vector in the body-locked coordinate system \( \mathbf{x}' \) (Fig.1)

Fig. 1. The two coordinate systems, \( \mathbf{x}' \) (body locked) and \( \mathbf{x} \) (external) used in the analysis; \( \varphi, \theta, \psi \) - Euler's angles.
Here, using the usual kinematic relationships between $\theta$, $\varphi$ ($\Psi = 0$) and $\omega_1$, $\omega_2$, $\omega'$, and the similarity transformation between the $x'$ and $x$ systems, we finally obtained that

$$\dot{\psi} = \sqrt{2} + \cotg \left( E_{31} c \varphi - E_{21} S \varphi \right)$$

$$- \lambda \left( S_{32} c \varphi - Q_1 S_2 \varphi \right)$$

and

$$\dot{\theta} = G_{213} \cos^2 \theta - G_{123} \sin^2 \theta + \frac{\lambda}{2} S_2 \theta \left( Q_2 + Q_1 S_2 \varphi + S_{32} S_2 \varphi \right)$$

in which

$$E_{ik} = \frac{1}{2} \left( \nabla_i \varphi + \lambda S_i \varphi \right), \quad G_{ijk} = E_{ij} c \varphi + E_{jk} S \varphi,$$

$$Q_1 = \frac{1}{2} \left( W_{22} - W_{33} \right), \quad Q_2 = \frac{1}{2} \left( W_{22} + W_{33} - 2 W_{11} \right), \quad V_{ik} = W_{ik} - W_{ki},$$

$$S_{ik} = W_{ik} - W_{ki}, \quad W_{ik} = \partial u_i / \partial x_k, \quad C_m \varphi = \cos m \varphi, \quad C^m \varphi = \cos^m \varphi,$$

$$S_m \varphi = \sin m \varphi, \quad S^m \varphi = \sin^m \varphi \quad \text{etc.}, \quad \lambda = ( R^2 - 1 ) / ( R^2 + 1 ), \quad R = a_1 / a_2.$$

Now, after non-dimensionalization by designating $\tilde{W}_{ik} = W_{ik} / W_0$ and $\tilde{t} = t W_0$ ($W_0$ - a typical gradient component), we could convert the Fokker-Planck equation to the form*

*The $\sim$ sign is dropped out for simplicity sake.
where \(D\) is the mid-diameter rotational diffusion coefficient of the axially symmetric particles. The normalization condition was taken, as usual, to be

\[
\int_0^{2\pi} \int_0^\pi F \sin \theta \, d\theta \, d\varphi = 1 .
\]

Solution of the Fokker-Planck Equation

According to the theory of Fourier series, we wrote down the solution to Eq. [5] as a series of spherical harmonics

\[
F = \sum_{n=0}^{\infty} \sum_{m=0}^{n} \left(1 - \frac{1}{2} \delta_{m0}\right) \left[A_{nm}^m(t) \cos \varphi + A_{-nm}^m(t) \sin \varphi \right] P_n^m(\cos \theta) .
\]

Thus, inserting [7] into [5] and taking account of the symmetry properties of the physical problem, we obtained for the \(A\)-coefficients the set of the simultaneous equations

\[
\frac{d A_{nm}^m}{dt} = -\frac{n(n+1)}{\lambda} A_{nm}^m - \sum_{j=1-n}^{n+1} \sum_{p=-n-2}^{m+2} \sum_{\ell=1}^2 (1 + \delta_{m0})
\]

\[
\times \left[D_{\ell,j}^\rho \rho_{nm}^\rho + (-1)^k C_{\ell,j}^\rho \rho_{mn}^\rho A_{1-k,j}^\rho \right] .
\]

in which \(D_{\ell,j}^\rho \rho_{nm}^\rho\), \(C_{\ell,j}^\rho \rho_{mn}^\rho\) are functions of \(S_{nk}, V_{nk}, Q_{nk}, Q_{n}\) and the size parameter \(\lambda\) defined above.

The latter were numerically solved by the employment of a fast differential equations-solver based on an extrapolation method of Burlish and Stoer.(11) It turned out that our general solution included previous work as special cases.

Numerical Results

Considering realistic situations of particles with a characteristic size of $r \sim 10^{-5} - 10^{-3}$ cm. (whose computed $D$ is $D \sim 1$ m.c. sec$^{-1}$), typical flow velocities and gradients of 1-10 m.sec$^{-1}$ and 1-10 sec$^{-1}$, respectively, we came out with Peclet number values of $\alpha \sim 1-10$.

As indicative examples, we bring out here the cases of:

i. A point source flow whose velocity is given by

$$u = \dfrac{q_0}{r^3}$$  \hspace{1cm} [9]

and whose gradient is

$$\nabla = \dfrac{6m}{r^3} - \dfrac{3x_i x_j}{r^5}$$  \hspace{1cm} [10]

where $x_i$ is normalized by a typical length $r_o$, $r(x_i)$ is the radius vector, $W = q_0/4\pi r_o^3$ and $q_0$ a constant.

ii. A round laminar jet whose axial ($u_z$) and radial ($u_r$) velocity components are (12)

$$u_z = \dfrac{2}{x_i} \gamma^2 x_i \gamma (\delta)$$  \hspace{1cm} [11]

and

$$u_r = \dfrac{\delta^2 \gamma}{x_i} (1 - \delta^2/4) \gamma (\delta)$$  \hspace{1cm} [12]

and the gradient components are
\[ W_{ii} = -\eta \left( 1 - \frac{3}{2} \frac{\lambda^2}{4} \right), \quad W_{ir} = -\delta \cdot \eta \cdot \frac{3}{8}, \quad W_{rr} = W_{ii} \frac{3}{8} / \delta, \]

\[ W_{rr} = \frac{1}{2} \eta \left( 1 - \frac{3}{2} \frac{\lambda^2}{4} + \frac{3^4}{16} \right) + \frac{U_r}{r}, \]

where \( \lambda = \delta \cdot r \cdot x, \quad \lambda (\delta) = \left( 1 + \frac{\lambda^2}{4} \right)^{-2}, \quad \delta \) is determined by

the jets' momentum \( J, \quad J \left( \frac{16}{3} \right) \Pi \cdot g \cdot \delta^2 \cdot \gamma^2 \), \( r \) is the radial
distance (again) and \( r, x, \) are later on non-dimensionalized by \( r_o \).

Indicative results for these two significant flows are presented in Figs. 2, 3
and 4, 5 in which a preferred orientation of the considered particles is clearly
seen by the pronounced maxima of \( F \).

Fig. 2. The orientation distribution function \( F \) vs. the (Euler)
angle \( \theta \) in a point source flow. \( \alpha = 1, \quad R = 0.02 \)
(platelets) and \( R = 50 \) (straight fibers).

\[ \tilde{t} \left( = t \cdot W_o \right) = 2, \quad \phi_1 = 1, \quad x_3 = x_5 = 0.4; \quad \phi - t = 0 \) (random orientation);

\[ R = 50: 1 - \phi = \theta, \quad \phi = \pi/4; \quad R = 0.02: 3 - \phi = 0.4 - \phi = \pi/4. \]
Fig. 3. A perspective view of particle orientation in a point source field (schematical).

Fig. 4. The orientation distribution function $F$ vs. the (Euler) angle $\theta$ in a flow of a laminar, axi-symmetric jet. $\alpha = 1, R = 0.01, 0.2, 5, 100$.

$\hat{e} = (t \ W \ b) \ \hat{z} \ \hat{x}, \ x_1 = 1, \ x_2 = x_3, \ \lambda = 0.5, \ \delta = 1, \ \psi = 0, \ \pi/4.$

1. $R = 0.01, \ \psi = 0$; 2. $R = 0.01, \ \psi = \pi/4$; 3. $R = 0.2, \ \psi = 0$;
4. $R = 0.2, \ \psi = \pi/4$; 5. $R = 5, \ \psi = 0$; 6. $R = 5, \ \psi = \pi/4$;
7. $R = 100, \ \psi = 0$; 8. $R = 100, \ \psi = \pi/4.$
Fig.5. A perspective view of particle orientation in a laminar jet (schematical)

Summary

The orientation distribution function of fibrous and platelet-like aerosol particles was calculated for a general laminar flow by solving the Fokker-Planck equation.

It has been found that this function shows maxima and minima, which indicates a preferred orientation. The cases of a point source and a laminar jet are brought out as an example.

Acknowledgement

The co-investigator was E.M. Krushkal.

Future Plans

Based on the reported study, the next stage of research on the orientation within a turbulent cloud is now in progress.
References

Appendix: Nomenclature

\( a_i, a_j, a_k \) - half axes of an ellipsoidal particle

\( A_{\ell m}, B_{\ell m} \) - coefficients in expansion as spherical harmonics

\( C_{\ell m}, D_{\ell m} \) - coefficients in Eq. [8]

\( \mathbf{D}, \mathbf{D} \) - rotational diffusion tensor and coefficient, respectively

\( E_{\ell m}, G_{\ell m}, \ell, \mu_1, \mu_2 \) - defined in text

\( F \) - orientation distribution function

\( i, j, k, l, m, \rho \) - indices

\( \mathbf{r} \) - radius vector; \( r_0 \) - normalizing radius vector

\( \mathbf{R} = a_i/\mu_2 \)

\( S_{\ell m}, S_{\rho \kappa} \) - defined in text

\( t \) - time

\( \mathbf{u} \) - flow velocity

\( V_{\ell m}, V_{\rho \kappa} \) - defined in text

\( W_{\ell m}, W_{\rho \kappa} \) - component of the gradient tensor; \( \mathbf{k} \) - normalizing component

\( X', \mathbf{x} \) - location vectors.

Greek Letters

\( \alpha \) - rotational Peclèt numbers

\( \chi \) - parameter related to jet's momentum

\( \delta_{ij} \) - Kronecker's delta

\( \phi, \theta, \psi \) - Euler's angles

\( \omega \) - rotational velocity of the particle

\( \nabla \) - nabla operator in angle-space

\( \Delta \) - Laplacian operator in angle-space
