PHASE I INSPECTION REPORT
NATIONAL DAM INSPECTION PROGRAM

DEPARTMENT OF THE ARMY
NEW ENGLAND DIVISION, CORPS OF ENGINEERS
WALTHAM, MASS. 02154

JULY, 1981
84 08 20 109.
**Title:** Williams Pond Dam

**Type of Report & Period Covered:** Inspection Report

**Performing Organization:**
U.S. Army Corps of Engineers
New England Division

**Report Date:** July 1981

**Number of Pages:** 60

**Security Class:** UNCLASSIFIED

**Distribution Statement:** APPROVAL FOR PUBLIC RELEASE: DISTRIBUTION UNLIMITED

**Supplementary Notes:**
Cover program reads: Phase I Inspection Report, National Dam Inspection Program; however, the official title of the program is: National Program for Inspection of Non-Federal Dams; use cover date for date of report.

**Keywords:** Dams, Inspection, Dam Safety,
Connecticut River Basin
Glastonbury, Connecticut

**Abstract:**
Williams Pond Dam is a stone masonry/concrete and earth embankment structure that is 17.1 ft. high and approximately 190 ft. long. The dam is judged to be in FAIR condition with several areas that require attention. The dam is classified as small and has a high hazard potential. The test flood according to these guidelines ranges from \( \frac{1}{6} \) the PMF to the PMF.
Honorable William A. O'Neil
Governor of the State of Connecticut
State Capitol
Hartford, Connecticut 06115

Dear Governor O'Neil:

Inclosed is a copy of the Williams Pond Dam (CT-00900) Phase I Inspection Report, prepared under the National Program for Inspection of Non-Federal Dams. This report is based upon a visual inspection, a review of the past performance and a brief hydrological study of the dam. I approve the report and support the findings and recommendations described in Section 7 and ask that you keep me informed of the actions taken to implement them. This follow-up action is vitally important.

Copies of this report have been forwarded to the Department of Environmental Protection, and to the owner, Adrian Goldman and Michael Stearn, Glastonbury, CT. Copies will be available to the public in thirty days.

I wish to thank you and the Department of Environmental Protection for your cooperation in this program.

Sincerely,

INCL

WILLIAM E. HODGSON, JR.
Colonel, Corps of Engineers
Acting Commander and Acting Division Engineer
NATIONAL DAM INSPECTION PROGRAM

PHASE I INSPECTION REPORT

Identification Number: CT 00900
Name: Williams Pond Dam
Town: Glastonbury
County and State: Hartford County, Connecticut
Stream: Hubbard Brook
Date of Inspection: May 18, 1981

BRIEF ASSESSMENT

Williams Pond Dam is a stone masonry/concrete and earth embankment structure that is 17.1 feet high and approximately 190 feet long. The downstream face is a vertical stone masonry wall which has been surfaced with concrete in the vicinity of the spillway and the upstream face is earth on a 2:1 slope. A two foot high by 1.5 foot wide concrete wall runs most of the length of the top of the dam. Near the south side of the dam is the main spillway which consists of a concrete weir that is 8 feet long. Concrete spillway abutments rise 4 feet above the spillway and atop the south abutment is a low-level discharge gate that controls a 2'x2' conduit through the base of the dam. Operating the gate requires the use of a portable hydraulic jack and will lower the pond in approximately four hours. There are three sealed off and abandoned intake structures which were once used for power supply and fire protection.

A wooden footbridge allows passage from one side of the spillway to the other. The downstream channel meanders alongside several apartment buildings with the first floor window sills only about 4 feet above the top of the channel. The channel is 3'x7' and is covered at some locations. On the north side of the pond is a semicircular auxiliary spillway with a total weir arclength of 53 feet that overflows into an 84 inch reinforced
concrete pipe which discharges into Hubbard Brook. Presently, the pond is used for recreation purposes only. The drainage area is 2.2 square miles and the reservoir has 25 acre-feet of storage capacity at the top of the dam.

The assessment of the dam is based on the available engineering data, the visual inspection and hydraulic/hydrologic computations. The dam is judged to be in FAIR condition with several areas that require attention. These areas include a low area of the crest at the south end of the dam that would result in premature overtopping of the dam, missing mortar from the downstream masonry, a rectangular opening through the concrete wall along the top of the dam as well as spalling over most of the concrete wall and spillway abutments, brush growing along the upstream side of the wall, debris in the downstream channel and overgrowth and spalling on the auxiliary spillway.

The dam is classified as SMALL and has a HIGH hazard potential in accordance with guidelines established by the Corps of Engineers. The test flood according to these guidelines ranges from 1/2 the Probable Maximum Flood (PMF) to the PMF. The test flood for this dam is 1/2 the PMF and is calculated to be 2,030 cfs. The combined spillway capacity at the top of the dam is 840 cfs or 41 percent of the test flood outflow. The test flood outflow would overtop the dam by 1.5 feet.

It is recommended that the owner engage the services of a qualified registered engineer experienced in the design of dams to design a solution to the low area at the south end of the dam, prepare a detailed hydraulic/hydrologic investigation to assess further the potential of overtopping and the need for and the means to increase the project discharge capacity, design and rebuild the concrete retaining wall at the outlet of the auxiliary spillway.
conduit and improve access to and means of raising and lowering the low-level discharge gate. It is also recommended that the owner repoint the masonry on the downstream face, repair the concrete wall at the top of the dam, remove the brush along the upstream side of the wall, clear the debris from the downstream channel, remove the overgrowth from and repair the auxiliary spillway, establish a formal warning system and initiate an annual technical inspection program.

The owner should implement the recommendations and remedial measures described above, and in greater detail in Section 7, within one year after receipt of this Phase 1 Inspection Report.

Joseph F. Merluzzo  
Connecticut P.E. #7639  
Project Manager

Gary J. Giroux  
Connecticut P.E. #11477  
Project Engineer
This Phase I Inspection Report on Williams Pond Dam (CT-00900) has been reviewed by the undersigned Review Board members. In our opinion, the reported findings, conclusions, and recommendations are consistent with the Recommended Guidelines for Safety Inspection of Dams, and with good engineering judgement and practice, and is hereby submitted for approval.

CARNEY M. TERZIAN, MEMBER
Design Branch
Engineering Division

JOSEPH W. FINEGAN, JR., MEMBER

Engineering Division

APPROVAL RECOMMENDED:

JOE B. PETER
Chief, Engineering Division
PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Inspections. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Inspection is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigations and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I Inspection; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through continued care and inspection can there be any chance that unsafe conditions be detected.

Phase I Inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established guidelines, the Spillway Test Flood is based on the estimated Probable Maximum Flood for the region (greatest reasonably possible storm runoff), or fractions thereof. Because of the magnitude and variety of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as necessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aide in determining the need for more detailed hydrologic and hydraulic studies considering the size of the dam, its general condition and the downstream damage potential.

The Phase I Inspection does not include an assessment of the need for fences, gates, "no trespassing" signs, repairs to existing fences and railings and other items which may be needed to minimize trespass and provide greater security for the facility and safety to the public. An evaluation of the project for compliance with Occupational Safety and Health Administration's (OSHA) rules and regulations is also excluded.

WILLIAMS POND DAM
SECTION 1 - PROJECT INFORMATION

1.1 GENERAL
a. Authority - Public Law 92-367, August 8, 1972 authorized the Secretary of the Army, through the Corps of Engineers, to initiate a National Program of Dam Inspection throughout the United States. The New England Division of the Corps of Engineers has been assigned the responsibility of supervising the inspection of dams within the New England Region. Storch Engineers has been retained by the New England Division to inspect and report on selected dams in the State of Connecticut. Authorization and notice to proceed were issued to Storch Engineers under a letter of May 1, 1981 from William E. Hodgson, Jr., Colonel, Corps of Engineers. Contract No. DACW33-80-C-0035 has been assigned by the Corps of Engineers for this work.

b. Purpose of Inspection -

(1) Perform technical inspection and evaluation of non-federal dams to identify conditions which threaten the public safety and thus permit correction in a timely manner by non-federal interests.

(2) Encourage and prepare the states to quickly initiate effective dam safety programs for non-Federal dams.

(3) To update, verify and complete the National Inventory of Dams.

1.2 Description of Project
a. Location - Williams Pond Dam is located in the Town of Glastonbury, Hartford County, Connecticut. The dam and pond are located just south of the
intersection of Williams Street East and the New London Turnpike. The coordinates of the dam are approximately 41°42.3' north latitude and 72°35.8' west longitude. The dam is located on Hubbard Brook in the Connecticut River Basin approximately 2.4 miles from the confluence with the Connecticut River.

b. Description of Dam and Appurtenances - Williams Pond Dam is comprised of stone masonry, concrete and earth embankment and is 17.1 feet high and approximately 190 feet long. A 2 foot high by 1.5 foot wide concrete wall runs the length of the dam. The bottom of this wall ranges from approximately 3.5 feet to 5 feet deep. The top of the dam is approximately 30 feet wide and is covered with well maintained grass. An earthen upstream face has a 2:1 slope and is completely underwater. The downstream face consists of a vertical stone masonry wall which has been surfaced with concrete in the vicinity of the main spillway.

The main spillway is located slightly closer to the southern side of the dam and is a weir 8 feet long. At this location, the entire downstream face of the dam is concrete on a 1:3 slope. Concrete spillway abutments rise 4 feet above the spillway and on the south spillway abutment there is a manually operated low-level discharge gate. This gate controls a 2'x2' opening through the base of the dam. Adjacent to the spillway is a wooden footbridge that allows passage from one side of the spillway to the other.

On the north side of the pond is an auxiliary spillway that is approximately 150 feet from the north end of the dam. The concrete weir is in the shape of a half-circle of radius 17 feet and it has an arclength of 53 feet. Below the spillway, the concrete slopes at approximately 1:2 for a vertical distance of 10 feet to the invert of an 84 inch reinforced concrete pipe that discharges into Hubbard Brook.
Three intake structures along the northern end of the dam which were once used for power supply and fire protection have since been completely sealed off on the upstream face.

c. Size Classification - Williams Pond Dam is 17.1 feet high and stores 25 acre-feet at the top of the dam. In accordance with the Recommended Guidelines for Safety Inspection of Dams established by the Corps of Engineers, the dam is classified as SMALL (height less than 40 feet, storage less than 1,000 acre-feet).

d. Hazard Classification - Williams Pond Dam is classified as having a HIGH hazard potential. Failure of the dam could result in the loss of more than a few lives and cause significant property damage. Immediately downstream from the dam, the flood wave would strike two apartment buildings. The first floor window sills of the apartments are approximately 7 feet above the streambed. Estimated flow and water depth at these locations just prior to dam failure is 180 cfs and 4 feet and just after dam failure is 3,090 cfs and 11.3 feet. Therefore, the water level would rise approximately 4.3 feet above the first floor window sills.

e. Ownership - Williams Pond Dam is owned by:

Adrian Goldman & Michael Stearn
The Soap Factory Apartments
222 Williams Street
Glastonbury, Connecticut 06033
(203) 659-1176

f. Operator - Operating personnel are under the direction of:

Mr. Joseph Gradowski, Property Manager
222 Williams Street
Glastonbury, Connecticut 06033

g. Purpose of Dam - The dam originally supplied power and provided fire protection to the J. B. Williams Company Soap Factory. The factory has subsequently been converted to apartments. Presently, the pond and dam are used for recreation purposes only.
h. Design and Construction History - Williams Pond Dam was constructed around 1900. No information is available on the original design or construction of the dam. Certain alterations were made to the dam in 1940 to protect the factory from flooding during heavy rains. An auxiliary spillway with an outlet conduit that bypasses the factory entirely was installed, the main spillway was narrowed and the spillway abutments were raised. Engineering drawings showing the alterations to the dam are included in Appendix B.

i. Normal Operational Procedures - There are no formal operational procedures for Williams Pond Dam. The low-level discharge gate can be hoisted using a portable hydraulic jack so that the pond can be lowered if necessary. The low-level discharge is inaccessible if the dam is overtopped.

1.3 Pertinent Data

a. Drainage Area - The Williams Pond drainage basin is located in the Town of Glastonbury, Connecticut and is irregular in shape. The area of the drainage basin is 1,420 acres or 2.2 square miles (Appendix D - Plate 5). Less than 5 percent of the drainage basin is natural storage and about 80 percent is undeveloped. The topography is rolling with elevations ranging from 535 above the National Geodetic Vertical Datum (NGVD) to 45.6 (NGVD) at the spillway crest.

b. Discharge at Damsite - There are no records available for discharge at the dam.

(1) Outlet works (conduit) size: 2'x2'
Invert elevation (NGVD): 36.5
Discharge Capacity at top of dam: 95 cfs

(2) Maximum known flood at damsite: Unknown
(3) Ungated spillway capacity at top of dam:
   Elevation (NGVD):
   MAIN | AUXILIARY
   180 cfs | 660 cfs
   49.6 | 49.6
(4) Ungated spillway capacity at test flood elevation:
   Elevation (NGVD):
   MAIN | AUXILIARY
   240 cfs | 720 cfs
   51.1 | 51.1
(5) Gated spillway capacity at normal pool elevation:
   Elevation (NGVD):

SECTION 2 - ENGINEERING DATA

2.1 Design Data

No original design computations or drawings are available for this dam. The most pertinent engineering drawings for the alterations to the dam made in 1940 are included in Appendix B. Other drawings and correspondence relating to these design alterations can be obtained through the State of Connecticut Department of Environmental Protection.

2.2 Construction Data

The dam was constructed around 1900. No original construction drawings or data are available. The most pertinent plans for the construction changes made to the dam in 1940 are included in Appendix B. Other plans, specifications and correspondence relating to these construction changes can be obtained at the Connecticut Department of Environmental Protection.

2.3 Operation Data

The dam at one time supplied industrial power and fire protection to the J. B. Williams Company Soap Factory. Presently, the dam is used for recreation purposes only. The low-level discharge gate is operable and a full description of the operating procedure is described in Section 3C. No operating records for this dam have been maintained.

2.4 Evaluation of Data

a. Availability - No original design, construction or operation data are available for this dam. Engineering drawings from the 1940 alterations to the dam and survey plans from a 1981 survey of the dam and pond were used in the preparation of this report.
b. Adequacy - The available information along with the visual inspection and hydraulic/hydrologic computations were adequate to assess the condition of the facility.

c. Validity - The conclusions and recommendations found in this report are based on the available information, the visual inspection and hydraulic/hydrologic computations.
SECTION 3 - VISUAL INSPECTION

3.1 Findings

a. General - A visual inspection was conducted on May 18, 1981 by members of the engineering staff of Storch Engineers. A copy of the visual inspection checklist is contained in Appendix A of this report. Selected photos of the dam are contained in Appendix C.

In general, the overall condition of the dam and its appurtenant structures is FAIR.

b. Dam - The dam is a stone masonry/concrete and earth embankment structure. A vertical stone masonry wall comprises the downstream face and in the vicinity of the spillway the masonry is covered with concrete on a 1:3 slope as shown in the Overview Photo. A stand of well maintained grass covers the top of the dam and a 2 foot high by 1.5 foot wide concrete wall runs along the length of the dam (Photo 1). The upstream earthen face is on a 2:1 slope and is completely underwater. Brush is growing at the top of the upstream face along the base of the concrete wall. (Photos 1 and 2).

The stone masonry on the downstream face in the vicinity of the spillway needs repointing (Overview Photo). Spalling is evident along the entire length of the concrete wall. There is a small rectangular opening (less than 1 square foot) through the base of the wall near the northern end of the dam (Plate 1). This will allow approximately 540 gpm of water to flow through the opening and onto the grass covered crest of the dam. (See computations Appendix D).

At the southern end of the dam where the wall ends and the drainage ditch outlets into the pond, the ground is approximately 1 foot lower than the top
of dam (Photo 3, Plate 1). There was a dike at this location at one time (Plate 3) that tied into an adjacent hill. The dike was removed during construction of the drainage ditch and the rehabilitation of the apartments. This low area would cause overtopping before the water reaches the top of dam elevation. There was no seepage passing through the dam.

c. Appurtenant Structures - The main spillway is an 8-foot long concrete weir which is in good condition. The concrete spillway abutments are in good condition, on their downstream face, immediately adjacent to the spillway where resurfacing has been done but are spalled elsewhere (Photo 2). On the downstream face below the spillway, the concrete is in good condition. The 53-foot long semicircular auxiliary spillway on the north side of the pond is heavily overgrown with vines (Photo 9). Spalling of the concrete weir was evident although the extent of the spalling was obscured due to the overgrowth. The 84-inch conduit is in good condition although spalling and exposed reinforcement occur at its outlet into Hubbard Brook (Photo 10). A short section of reinforced concrete retaining wall along the bank of this outlet stream is severely cracked and is falling into the stream (Photo 10).

There is a low-level discharge mechanism at the south side of the spillway that controls a 2'x2' conduit that passes through the base of the dam (Photos 5 and 6). The gate consists of a 3/8 inch thick steel plate which slides along vertical tracks. To operate the gate requires a portable hydraulic jack which is available at the site. The jack lifts a steel cable (Photo 5) which is attached to the plate (Photos 1 and 2). It takes only a few minutes to set up the jack and emptying the pond takes about 4 hours. Operation while the dam is being overtopped would be difficult as
someone must stand on the spillway abutment to operate the jack. Adjacent to the spillway is a wooden footbridge supported by steel beams to allow passage to either side of the spillway (Photo 1). The footbridge is structurally stable.

There are three intake structures on the northern side of the dam (Photo 4, Plate 3). One structure controls two 10 inch fire protection conduits and each of two other structures controls a 30 inch power conduit. All the pipes are no longer used and have been sealed at the upstream side.

d. Reservoir Area - The area immediately adjacent to the pond is gently sloped and in a natural state. The shoreline shows no signs of sloughing or erosion. A rise in the water level of the pond will not endanger life or property, except at the south abutment where water can prematurely flow over a low section of the dam and flood some apartments (Photo 3).

e. Downstream Channel - The downstream channel runs under a concrete patio for a distance of 150 feet where it emerges as a 3 foot high by 7 foot wide channel with stone masonry side walls (Plate 1, Photo 8). The entrance where it passes under the patio is approximately 25 feet from the dam and is cluttered with debris (Photo 7). The channel winds around an apartment complex and passes under numerous walkways and footbridges along its route.

3.2 Evaluation

Overall, the general condition of the dam is FAIR. The visual inspection revealed items that led to this assessment, such as:

a. Missing mortar in the downstream masonry face;

b. Spalling of the concrete wall along the top of dam;
c. Brush growing along the upstream face of the concrete wall;
d. A rectangular opening in the concrete wall that could cause some erosion on the grass covered crest of the dam;
e. A low area at the southern end of the dam that would cause premature overtopping of the dam;
f. Debris in the downstream channel;
g. Overgrowth and spalling on the auxiliary spillway;
h. A collapsing retaining wall at the outlet to the auxiliary spillway conduit.
i. Inadequate means of raising the low-level discharge gate.
SECTION 4 - OPERATIONAL AND MAINTENANCE PROCEDURES

4.1 Operational Procedures
   a. General - At one time the dam supplied power and fire protection to the J. B. Williams Company Soap Factory. Presently, the dam is used for recreation purposes only. The water level can be controlled by a low-level discharge gate which can be operated by using a hydraulic jack as described in Section 3.

   b. Description of Any Warning System in Effect - There is no formal warning system in effect for this dam.

4.2 Maintenance Procedures
   a. General - There is no specific maintenance program for this dam.

   b. Operating Facilities - The low-level discharge is operable. The power and fire protection conduits are sealed off at the intake structures.

4.3 Evaluation
   There is no regularly scheduled maintenance program. A systematic and complete maintenance program should be instituted at the dam and a formal warning system should be developed.
SECTION 5 - EVALUATION OF HYDRAULIC/HYDROLOGIC FEATURES

5.1 General

Williams Pond Dam is a stone masonry/concrete and earth embankment dam that is 17.1 feet high and approximately 190 feet long. The main spillway is 8 feet long and is located slightly closer to the south side of the dam. There is a manually operated low-level discharge gate on the south spillway abutment. On the north side of the pond is an auxiliary spillway in the shape of a half-circle of radius 17 feet. The weir has an arclength of 53 feet and a width of 3 feet and the drop is 8.5 feet to the invert of an 84 inch reinforced concrete pipe.

The watershed encompasses 2.2 square miles and is approximately 80 percent undeveloped. Rolling topography is characteristic of the region with terrain rising to 489 feet from the spillway crest.

The pond has a total capacity of approximately 7 acre-feet at the spillway crest and approximately 25 acre-feet when the pond is at the top of the dam.

5.2 Design Data

No design data are available for the original dam, however, engineering drawings for alterations made to the dam in 1940 are included in Appendix B.

5.3 Experience Data

No historical data for recorded discharges or water elevations are available for this dam, however, the dam has withstood past major floods such as; March 1936 and September 1938 as well as January and February 1978 and January 1979. The flood of record in the Glastonbury area resulted from the storm of September, 1938.
5.4 Test Flood Analysis

Based on the Recommended Guidelines for Safety Inspection of Dams, the dam is classified as a SMALL structure with a HIGH hazard potential. The test flood for these conditions ranges from 1/2 the probable maximum flood (PMF) to the PMF. One half of the PMF was used for this dam because of the dam's small size.

Using guide curves established by the Corps of Engineers (rolling terrain), the test flood inflow is 2,110 cfs. The routing procedure established by the Corps' guidelines gives an approximate outflow of 2,030 cfs. The combined spillway capacity of the dam is approximately 840 cfs or 41 percent of the routed test flood outflow. The test flood would overtop the dam by 1.5 feet.

Approximately 2,000 feet upstream from Williams Pond Dam is Rosers Pond Dam which controls flow into Williams Pond Dam. In the development of the test flood inflow, it was assumed that the peak outflow from Rosers Pond Dam and the peak runoff from the independent watershed occurred at the same time. Storage behind the dam was assumed to begin at the elevation of the spillway crest. Storage was determined by an average area depth analysis. Capacity curves for the spillways assumed a broad crested weir.

5.5 Dam Failure Analysis

A dam failure analysis was performed using the Rule of Thumb method in accordance with guidelines established by the Corps of Engineers. The breach width was taken as 40 percent of the dam length at midheight which calculated to be 32 feet. Failure was assumed to occur when the water level in the pond was at the top of the dam.

The main spillway discharge just prior to dam failure is 180 cfs and the calculated dam failure discharge is 3,805 cfs.
Failure of Williams Pond Dam could result in the loss of more than a few lives and cause significant property damage which gives this dam a HIGH hazard potential classification. Immediately downstream of the dam is an apartment complex with first floor window sills approximately 7 feet above the streambed. Estimated flow and water depths at this location just prior to dam failure is 180 cfs and 4 feet respectively and just after dam failure is 3,090 cfs and 11.3 feet. Therefore, the water level would rise approximately 4.3 feet above the first floor window sills of the apartments which would result in significant flooding to the 24-first floor apartments in the two apartment buildings that would be affected at the site.
SECTION 6 - EVALUATION OF STRUCTURAL STABILITY

6.1 Visual Observations

The general structural stability of the dam is good as evidenced by the vertical, horizontal and lateral alignment. The earth embankment portions of the dam also show no evidence of instability. Spalling is evident on the 2-foot high concrete wall along the top of the dam and the stone masonry on the downstream face needs repointing. The auxiliary spillway structure is stable although the weir is spalled substantially.

6.2 Design and Construction Data

The dam was constructed around 1900. No original design or construction information is available.

6.3 Post-Construction Changes

Certain alterations were made to the dam in 1940 to protect the factory from flooding during heavy rains. An auxiliary spillway was added, the main spillway was narrowed and the spillway abutments were raised. The engineering drawings showing the most pertinent of these alterations are included in Appendix B. It is assumed that the low area at the south end of the dam was a result of the dike being cut down during construction of the drainage ditch and rehabilitation of the apartments.

6.4 Seismic Stability

The dam is located in Seismic Zone 1 and in accordance with Recommended Phase 1 Guidelines does not warrant a seismic analysis.
SECTION 7 - ASSESSMENT, RECOMMENDATIONS AND REMEDIAL MEASURES

7.1 Dam Assessment

a. Condition - After consideration of the available information, the results of the inspection, contact with the owner and hydraulic/hydrologic computations, the general condition of the Williams Pond Dam is FAIR.

b. Adequacy of Information - The information available is such that the assessment of the safety of the dam was based on the available information, the visual inspection results and computations developed for this report.

c. Urgency - It is considered that the recommendations and remedial measures suggested below should be implemented by the Owner within one year after receipt of this Phase I Inspection Report.

7.2 Recommendations

It is recommended that the Owner employ a qualified registered engineer to:

a. Design a solution to and oversee the reconstruction of the low area at the south end of the dam such as an earth dike or an extension of the concrete wall.

b. Prepare a detailed hydraulic/hydrologic investigation to assess further the potential of overtopping and the need for and the means to increase the project discharge capacity.

c. Design and rebuild the concrete retaining wall at the outlet of the auxiliary spillway conduit.

d. Improve access to and means of raising and lowering the low-level discharge gate.
7.3 Remedial Measures

a. Operation and Maintenance Procedures -

(1) Repoint the stone masonry in the downstream face of the dam.

(2) Repair the spalling at the abutments of the principal spillway and along the concrete wall and fill the rectangular opening with concrete.

(3) Remove the overgrowth from the auxiliary spillway and repair the spalled concrete weir.

(4) Remove the brush growing along the upstream side of the concrete wall along the top of the dam.

(5) Clear the debris from the downstream channel where it passes underneath the patio.

(6) Institute a program of annual technical inspection by a qualified engineer.

(7) Develop plans for around-the-clock surveillance for periods of unusually heavy rains and institute a formal downstream warning system for use in the event of an emergency.

7.4 Alternatives

There are no practical alternatives to the above recommendations.

Stage-discharge curves for all flows out of apartment complex area.

D-13

Discharge (cfs)
FLOW THROUGH RECTANGULAR OPENING IN CONCRETE WALL

Determine flow through opening

**ELEVATION A-A**

- Concrete Wall (See Plate 1)
- Rectangular Opening
- Existing Ground

**PLAN**

- Use inlet control
- \( H/W = 2.67 \)
  \[ Q/b = 1.7 \quad b = 0.7' \]
  \[ Q = 1.2 \, cfs = 540 \, gpm \]
  \[ V = 2.85 \, fps \]

Determine erosion due to flow through opening

- Use Connecticut Erosion and Sediment Control Handbook pg. 5.15

- Kentucky bluegrass
- 0-5% slope
- Permissible velocity = 6 fps
- Assume intermediate k value = 0.35

Initial velocity = 9 fps but this will diminish quickly as water spreads out over the grass covering the top of dam. Therefore some erosion will occur at the outlet of the rectangular opening, but this location is well beyond the area where breaching could occur, so there is no threat to the integrity of the dam.
APPENDIX E

INFORMATION AS CONTAINED IN THE NATIONAL INVENTORY OF DAMS
