VISCOSITY SOLUTIONS OF HAMILTON-JACOBI EQUATIONS AT THE BOUNDARY

Michael G. Crandall and Richard Newcomb

Technical Summary Report #2723
July 1984

ABSTRACT

At the classical level, when one considers boundary value problems for nonlinear scalar first order partial differential equations there are parts of the boundary where one does not expect to be able to prescribe boundary data. Likewise, uniqueness theorems can be proved for solutions which are prescribed only on parts of the boundary. However, globally defined classical solutions of first order nonlinear problems are rare, owing to the formation of "shocks". This theoretical difficulty has recently been overcome for equations of Hamilton-Jacobi type via the development of the theory of viscosity solutions, a sort of generalized solution for which good existence and uniqueness theorems hold. This note is concerned, in the context of viscosity solutions, with identifying parts of the boundary which are irrelevant for a given equation from the point of view of requiring data in order to prove uniqueness. This involves knowing when a viscosity solution of an equation (in the viscosity sense) in the interior of the domain may be extended by continuity to a solution in the viscosity sense to points on the boundary. The results obtained to this effect are supplemented by examples delimiting their sharpness.

AMS (MOS) Subject Classifications: 35D99, 35F30

Key Words: Hamilton-Jacobi equations, viscosity solutions, uniqueness, boundary value problem, first-order nonlinear partial differential equations.

Viscosity Solutions of Hamilton–Jacobi Equations at the Boundary
by
Michael G. Crandall and Richard Newcomb

Introduction.

We begin by recalling an important notion of generalized solutions for scalar nonlinear first order partial differential equations. Let $K$ be a subset of $\mathbb{R}^n$ and $F:K \times \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ be continuous (i.e., $F \in C(K \times \mathbb{R}^n \times \mathbb{R}^n)$). A function $u \in C(K)$ is called a viscosity solution of $F(y,u,Du) < 0$ on $K$ if for each real-valued function $\psi$ which is continuously differentiable in a neighborhood of $K$ and each local maximum $z \in K$ of $u - \psi$ relative to $K$ one has

$$F(z,u(z),Du(z)) < 0.$$  

(0.1)

Here $D\psi = (\frac{\partial \psi}{\partial y_1}, \ldots, \frac{\partial \psi}{\partial y_n})$ is the gradient of $\psi$. We will use the notation $C^1(K)$ to mean the set of functions which are defined and continuously differentiable in a neighborhood of $K$. Similarly, a viscosity solution of $F(y,u,Du) > 0$ in $K$ is a $u \in C(K)$ such that for every $\psi \in C^1(K)$ and local minimum $z \in K$ of $u - \psi$ relative to $K$ one has

$$F(z,u(z),Du(z)) > 0.$$  

(0.2)

A viscosity solution of $F = 0$ on $K$ is a function which is a viscosity solution of both $F < 0$ and $F > 0$. We also call viscosity solutions of $F < 0$ ($F > 0$) viscosity subsolutions (respectively, supersolutions) of $F = 0$. Observe that these notions do not require $u$ to be anywhere differentiable. Indeed, although we will not do so here, there are circumstances when it is appropriate to require only a semicontinuity of $u$ rather than continuity. The set $K$ is also general – we have not yet restricted it in any way – but we will primarily be concerned with cases in which $K$ satisfies

$\Omega \subset K \subset \overline{\Omega}$, where $\Omega$ denotes an open subset of $\mathbb{R}^n$, $\overline{\Omega}$ is its closure and $\partial \Omega$ is its boundary.

The notion of viscosity solutions has become important in providing a theoretical basis for the interaction between equations of Hamilton-Jacobi type, control theory and differential games. The first uniqueness theorems using this notion are proved in Crandall and Lions [4]. Crandall, Evans and Lions [3] provides a simpler introduction to the subject while the book Lions [8] and the review paper Crandall and Souganidis [6] provide a view of the scope of the theory and the references to much of the recent literature.

While one primarily had the case in which \( F \) is open in mind in the theory referred to above, [4, Remark 1.13] pertained to the general case. Moreover, in [4, Proposition V.1] it is proved that a viscosity solution of

\[
\frac{\partial u}{\partial t} + H(x,t,u,\nabla u) = 0 \quad \text{on } O \times (0,T)
\]

where \( O \) is an open subset of \( \mathbb{R}^N \) and \( \nabla u = (u_{x_1}, \ldots, u_{x_N}) \) is the spatial gradient of \( u \), which happens to extend continuously to \( \partial O \times (0,T) \) is also a viscosity solution on the set \( \partial O \times (0,T) \). See also [3, Lemma 4.1]. Of course, (0.3) is subsumed under the general case above by putting \( N = N + 1, \ y_1 = x_1, \ldots, y_{N-1} = x_{N-1}, \ y_N = t, \) and

\[
F(y,u,(P_1, \ldots, P_{N+1})) = P_{N+1} + H((y_1, \ldots, y_N),y_{N+1},u, (P_1, \ldots, P_N)).
\]

It is further remarked in [4] that this extension property depends on a certain monotonicity of the equation in the direction of the normal to the domain, and this is the point we will examine in some generality in this note.

Our current interest in this point is partly generated by recent remarks of R. Jensen [7]. Jensen had the idea of formulating the uniqueness theorem on arbitrary closed sets, a formulation with attractive features. Our main results, which we introduce and prove in Section 1, are criteria which identify boundary points at which an inequation is automatically satisfied in the viscosity sense if it holds in the interior of a set, extending the above mentioned result for (0.3). Examples establishing the sharpness of the result are also given, and we formulate corresponding uniqueness theorems.
Section 1. The Extension Theorem and Examples

In this section Ω denotes an open subset of \(\mathbb{R}^n\) and \(\partial \Omega\) is its boundary. We consider sub- and supersolutions \(u \in C(\bar{\Omega})\) of an equation \(F = 0\) on \(\Omega\) and define a subset \(\Gamma_{\Omega}\) of \(\partial \Omega\) (which we call the part of \(\partial \Omega\) irrelevant for \(F\)). In nice situations \(u\) is then a sub- or supersolution (as appropriate) of \(F = 0\) on \(\Omega \cup \Gamma_{\Omega}\). We will be concerned about how general \(u, \Omega\) and \(F\) may be and still have the result hold. With this in mind, we shall make the definitions for a general open set \(\Omega\). We need to define an appropriate set of normals to a point \(z \in \partial \Omega\). The open ball of radius \(r\) centered at \(z\) in \(\mathbb{R}^n\) will be denoted by \(B_r(z)\); i.e.

\[B_r(z) = \{y \in \mathbb{R}^n : |y - z| < r\}.

Definition 1. Let \(z \in \partial \Omega\). Then \(v \in \mathbb{R}^n\) is an inward normal to \(\Omega\) at \(z\) if there is a \(\lambda > 0\) for which the open ball of radius \(|\lambda v|\) centered at \(z + \lambda v\) is contained in \(\Omega\), i.e.

\[B|\lambda v|(z + \lambda v) \subseteq \Omega.

The set of all inward normals to \(\Omega\) at \(z \in \partial \Omega\) is denoted by \(N_\Omega(z)\). Another description of \(N_\Omega(z)\) can be given the following way: For each \(y \in \mathbb{R}^n\) there are points of \(\partial \Omega\) which are nearest \(y\). Let \(P_y\) be the set of such points:

\[(1.1) \quad P_y = \{z \in \partial \Omega : |y - z| < |y - w| \text{ for } w \in \partial \Omega\}.

Then

\[(1.2) \quad N_\Omega(z) = \{\lambda(y - z) : y \in \partial \Omega, z \in P_y, \lambda > 0\},

that is, the inward normal vectors are just those in the directions from \(z\) to points in \(\partial \Omega\) for which \(z\) is a nearest point in \(\partial \Omega\). We remark that there are a variety of choices for the definitions of "normal" and "tangent" vectors to an arbitrary set. We are using a notion appropriate for our purposes - as regards others and relationships among them, see Clarke [2] and Aubin and Ekeland [1]. The reader can easily convince himself that \(N_\Omega(z)\) may be empty and it may be \(\mathbb{R}^n\setminus\{0\}\) when \(z \in \partial \Omega\).
**Definition 2.** Let $z \in \partial \Omega$. Then $z \in I_F$ if there is an $r > 0$ such that for all $y \in \partial \Omega \cap B_r(z)$ and all $v \in N_\Omega(y)$ and all $(u,p) \in E \times \mathbb{R}$

$$P(y,u,p+v) < P(y,u,p).$$

(1.3)

In other words, $z$ is irrelevant for $F$ if $F$ is nonincreasing in the inward normal directions in a neighborhood of $z$. Of course, $I_F$ depends on $\Omega$ as well as $F$, but we won't need to indicate this in this note.

**Remark.** Observe that the set of vectors $v$ for which (1.3) holds for all $p \in \mathbb{R}^n$ is closed under addition. Using this and the continuity of $F$ we deduce that if $z \in I_F$ then

$$P(z,u,p+v) < P(z,u,p)$$

for all $v$ in the closed convex hull of $\limsup_{y \to z} N_\Omega(y)$, which may well be a much larger set than $N_\Omega(z)$.

We would like to prove that if $u \in C(\partial \Omega)$ is a viscosity sub- or supersolution of $F = 0$ in $\Omega$, then it is also a viscosity sub- or supersolution in $\Omega + I_F$, but this is not true without further restrictions. To formulate our first result we still need to define "regular points" of $\partial \Omega$. These will be defined by properties of the function

$$d(y) = \inf \{|y - w|^2; w \in \partial \Omega\},$$

which is the square of the distance from $y$ to $\partial \Omega$. Associated with $d(y)$ is the mapping $F$ of (1.1). Indeed

$$P_y = \{w \in \partial \Omega; d(y) = |y - w|^2\}.$$ 

If $P_y$ is a singleton (i.e., there is only one point in $\partial \Omega$ nearest $y$), we will abuse notation and also use $P_y$ to denote this closest point.

**Definition 3.** Let $z \in \partial \Omega$. Then $z$ is regular for $\Omega$ if there is an $r > 0$ such that if $y \in B_r(z) \cap \Omega$, then $P_y$ is a singleton, $d$ is differentiable at $y$ and

$$d(y) = 2(y - P_y).$$

(1.5)

**Remark.** It is a standard and elementary exercise to show that if $\Omega$ is of class $C^2$ near $z \in \partial \Omega$, then $z$ is regular for $\Omega$. 

4
Theorem 1. Let $F \in C(Q \times \mathbb{R}^d)$. Let $z \in I_p$ be regular for $Q$, $u \in C(Q \times I_p)$ be Lipschitz continuous near $z$ and $u$ be a viscosity solution of $F < 0$ ($F > 0$) on $Q$. Then $u$ is also a viscosity solution of $F < 0$ (respectively, $F > 0$) on $Q_+(z)$. In particular, if $u$ is a viscosity solution of $F = 0$ on $Q$, then it is a viscosity solution on $Q_+(z)$.

Before proving this result, we give two examples. The first shows that the restriction to Lipschitz continuous $u$'s is necessary in this generality, while the second shows that if $z$ is not regular for $Q$ the result may fail.

Example 1. Consider the situation $Q = (0,1)$ and
$$F(x,u,u') = x^a u' - 1 = 0,$$
where $0 < a < 1$. In this example, $0 \in I_p$, since $F(0,u,p)$ is independent of $p$ and hence is nonincreasing in all directions. Moreover, 0 is clearly regular for $Q$. The function $u = x^{(1-a)/(1-a)}$ is a classical (and hence viscosity) solution of $F = 0$ on $Q$. However, $u$ is not Lipschitz continuous near 0. If $\Phi(x) = x$ then $u - \Phi$ is a minimum relative to $Q = (0,1)$ at 0 but $F(0,u(0),u'(0)) = -1 < 0$, so $u$ is not a viscosity supersolution on $(0,1)$.

Example 2. Let $M = 2$ and $(x,y)$ denote points of $\mathbb{R}^2$. Put $Q = \{(x,y) \in \mathbb{R}^2 : 0 < y < x^2, 0 < x < 1\}$ and
$$F(x,y,u,u_x,u_y) = u_x + 3(y)u_y,$$
We have
$$u_{00} = u_{xy} = u_{yy} = 0$$
if $(x,y) = (0,0)$.

$$H_Q((x,y)) = \begin{cases} \lambda(2x,-1); \lambda > 0 & \text{if } (x,y) = (x,x^2), 0 < x < 1, \\
(0,\lambda); \lambda > 0 & \text{if } (x,y) = (0,x), 0 < x < 1.
\end{cases}$$

and it is straightforward to check that $(0,0) \in I_p$. For example, $F$ is nonincreasing in a direction $v = (v_x,v_y)$ at a point $(x,x^2)$ exactly when (using the linear form (1.6) of $F$)
$$v_x + 3(x^2)v_y = v_x + 3xv_y < 0.$$
For the normal \( \nu = (2x, -1) \) this quantity is \( 2x - 3x < 0 \). Now \( u = 0 \) is a Lipschitz continuous viscosity solution of \( F = 0 \) in \( \Omega \). The function \( 0 - x = -x \) has a maximum on \( \Omega \) at \( (0, 0) \), but \( F(0, 0, (1, 0)) = 1 > 0 \), so \( 0 \) is not a viscosity subsolution on \( \Omega \) at \( (0, 0) \). (We conclude that \( (0, 0) \) is not regular and the requirement of regularity cannot be relaxed.)

**Proof of Theorem 1.** Let \( u \in C(\Omega \cup I_\nu) \) be (locally) Lipschitz continuous and a viscosity solution of \( F = 0 \) in \( \Omega \). Let \( z \in I_\nu \) be regular for \( \Omega \). Put

\[ \Omega_z = \Omega \cup \{z\} \]

If \( \varphi \in C^1(\Omega_z) \) and \( u - \varphi \) have \( z \) as a local maximum relative to \( \Omega_z \) (and hence relative to a neighborhood of \( z \) in \( \Omega \)). We seek to prove that

\[ (1.7) \quad F(z, u(z), D\varphi(z)) < 0. \]

Without loss of generality we may assume that for each small \( r > 0 \)

\[ (1.8) \quad u(y) - \varphi(y) < u(z) - \varphi(z) \text{ for } y \in \bar{\Omega} \text{ and } |y - z| < r, \]

that is, the maximum is strict. This is because \( \varphi \) can be perturbed to \( \varphi(y) + |y - z|^2 \) which makes \( z \) a strict maximum without affecting \( D\varphi(z) \). Let \( \varepsilon > 0 \). We claim that

\[ (1.9) \quad V_\varepsilon(y) = u(y) - \varphi(y) - \varepsilon \theta(y) \]

has a local maximum \( y_\varepsilon \in \bar{\Omega} \) relative to \( \bar{\Omega} \) satisfying

\[ (1.10) \quad y_\varepsilon = z \text{ as } \varepsilon \to 0. \]

Indeed, because \( u - \varphi \) is continuous, for each small \( r > 0 \) we can find \( w \in B_r(z) \cap \bar{\Omega} \) such that (1.8) holds with \( w \) in place of \( z \):

\[ (1.11) \quad u(y) - \varphi(y) < u(w) - \varphi(w) \text{ for } y \in \bar{\Omega} \text{ and } |y - z| = r, \]

Now consider \( V_\varepsilon \) in the set \( B_r(z) \cap \bar{\Omega} \). We will argue informally, as it is best if the reader convinces himself of the validity of what follows: \( V_\varepsilon \) tends to \( -\theta \) on \( \partial \Omega \). On the other hand, we can guarantee that \( V_\varepsilon(y) < V_\varepsilon(w) \) on \( |y - z| = r \) away from \( \partial \Omega \) by choosing \( \varepsilon \) small, because of (1.11), and we can make \( V_\varepsilon(w) \) as close as we please to \( u(w) - \varphi(w) \). The existence of local maxima \( y_\varepsilon \) satisfying (1.10) follows, as does the fact that we can guarantee
\[(1.12) \quad Y_C(y_C) + u(z) - \psi(z).\]

Next let \( z \) be nearest points to \( y_C \) in \( \Delta \); \( z_C = P_C. \) Then, by the assumption that \( u \) is a viscosity subsolution in \( \Omega \), the regularity of \( z \) and (1.5)

\[(1.13) \quad F(y_C, u(y_C), D\psi(y_C) - 2\varepsilon(y_C) - z_C/(d(y_C))^2 < 0.\]

With future uses in mind, we put

\[(1.14) \quad \nu_C = D\psi(y_C), \quad \lambda_C = (y_C - z_C), \quad \rho_C = 2\varepsilon/(d(y_C))^2, \]

and write (1.13) as

\[(1.15) \quad F(y_C, u(y_C), \nu_C - \lambda_C \nu_C) - F(s_C, u(y_C), \rho_C - \lambda_C \nu_C) +
\quad + F(s_C, u(y_C), \rho_C - \lambda_C \nu_C) < 0.\]

We treat the various terms of this inequality: First, since \( u \) is Lipschitz continuous,

\[(1.16) \quad |\rho_C - \lambda_C \nu_C| < L\]

where \( L \) is a Lipschitz constant for \( u \) in the neighborhood of \( z \) in which \( y_C \) lies.

[See (4, Lemma II.3)]. Since \( y_C, z_C \in \Delta \), we may use (1.15) and the continuity of \( F \) to conclude that the difference comprised by the first two terms in (1.14) tends to 0 with \( \varepsilon \). As regards the last term, observe that \( z_C \in \Delta \) and \( \nu_C \notin \partial \Omega(s_C) \) imply, because \( z \in \partial \Omega \), that

\[(1.17) \quad F(s_C, u(y_C), \rho_C - \lambda_C \nu_C) > F(s_C, u(y_C), \rho_C).\]

Using (1.17) and the prior remark together with (1.15), we may pass to the limit as \( \varepsilon \rightarrow 0 \) to find (1.7) as desired. The case of supersolutions is handled in the parallel way, and the case of solutions follows from the sub and super cases.

At this point we have not even recovered the results for \( (0.3) \) mentioned above, as they do not require Lipschitz continuity of \( u \). By Example 1 it is clear that further restrictions are needed on \( F \) in order to deal with more general \( u \)'s. Looking at the proof of Theorem 1 and Example 1 will make the condition we are about to formulate more palatable.
**Definition 4.** Let \( z \in I_p \). Then \( z \) is regular for \( F \) if for all sequences \( z_n \in \partial \Omega \) and \( y_n \in (N_0(z_n) + z_n) \cap \Omega \) convergent to \( z \) and \( \lambda_n > 0 \) satisfying

\[
\lambda_n |y_n - z_n|^2 + 0
\]

we have

\[
\lim \inf_{n \to \infty} F(y_n, u, p - \lambda_n(y_n - z_n)) - F(z_n, u, p - \lambda_n(y_n - z_n)) > 0
\]

uniformly for bounded \( u \) and \( p \).

In particular, the continuity requirement we are imposing is laid only on the behaviour of \( F \) near \( z \) and in appropriate directions. We have:

**Theorem 2.** Let \( F \in C(\Omega \times \mathbb{R}^m) \). Let \( z \in I_p \) be regular for \( \Omega \) and \( F \), \( u \in C(\Omega + I_p) \) be a viscosity solution of \( F < 0 \) (\( F > 0 \)) on \( \Omega \). Then \( u \) is also a viscosity solution of \( F < 0 \) (respectively, \( F > 0 \)) on \( \Omega + \{ z \} \). In particular, if \( u \) is a viscosity solution of \( F = 0 \) on \( \Omega \), then it is a viscosity solution on \( \Omega + \{ z \} \).

**Proof.** The proof follows the proof of Theorem 1 exactly up to the discussion of (1.15). With the notation (1.14), the relation (1.16) no longer holds for any \( L \). However, \( p \) is bounded and if we observe that

\[
\lambda_c |v_c|^2 = \lambda_c |y_c - x_c|^2 = 2c/d(y_c) + 0,
\]

as follows immediately from (1.12) and the definition of \( y_c \), then the assumption that \( z \) is regular for \( F \) may be used to claim that

\[
\lim \inf_{\varepsilon \to 0} (F(y_c, u(y_c), p_c - \lambda_c v_c) - F(z_c, u(y_c), p_c - \lambda_c v_c)) > 0
\]

and the proof is completed as before.

**Example 3.** We may use the situation of Example 1 to show that the "rate" in (1.18) is sharp among power laws. Indeed, with the notation of Example 1, if \( z_n = 0 \) for all \( n \) and \( y_n \) is a sequence of positive numbers convergent to zero which satisfies

\[
\lambda_n |y_n - z_n|^{1 + \alpha} = \lambda_n (y_n)^{1 + \alpha} + 0
\]

we have

\[
F(y_n, u, p - \lambda_n y_n) - F(0, u, p - \lambda_n y_n) = y_n^{1 + \alpha} - \lambda_n y_n^{1 + \alpha} + 0
\]

uniformly for bounded \( p \). That is, the assumptions of Theorem 2 are satisfied except
that the exponent 2 in (1.18) is replaced by $1 + a$. Yet we know that the viscosity solution $x^{(1-a)/2} / (1 - a)$ of $F = 0$ on $(0, 1)$ is not a supersolution on $[0, 1)$.

Remarks. The proof of Theorems 1 and 2 couples the general line of argument used in the special case (0.3) in [4] and [3] with the use of the distance function to replace the particular construction used in this case. Use of the distance function is frequently advantageous in proofs in this subject (see, for example, Lions [8], [9] and Jensen [7]). By the way, it is an elementary (and standard) exercise to show that $u(x) = (d(x))^{1/2}$ is a viscosity solution of $|Du|^2 = 1$ in $\Omega$ whether or not $\partial \Omega$ is smooth. It is the only viscosity solution of this equation vanishing on $\partial \Omega$ (see [8] and [4]).

Finally, we formulate uniqueness theorems corresponding to Theorems 1 and 2. There are many possible variants of these results, and these are chosen to simply illustrate the interaction between Theorems 1 and 2 and uniqueness. Corresponding Theorem 1 we have:

Theorem U1. Let $\Omega$ be a bounded open subset of $\mathbb{R}^n$. Let $F \in C(\Omega \times \mathbb{R}^n)$ satisfy:

For $R > 0$ there is a strictly increasing function $\gamma_R$ such that $\gamma_R(0) = 0$ and $F(y,u,p) - F(y_1,u,v) > \gamma_R(u - v)$ for $y \in \Omega, p \in \mathbb{R}^n$ and $u, v \in [-R, R]$.

Let $u, v \in C(\Omega)$ be Lipschitz continuous, $u$ be a viscosity solution of $F < 0$ and $v$ be a viscosity solution of $F > 0$ on $\Omega$. Let each point of $\partial \Omega$ be regular for $2$. Let $u < v$ on $\partial \Omega \setminus I_F$, then $u < v$ in $\Omega$.

Corresponding to Theorem 2 we have:

Theorem U2. Let $\Omega$ and $F$ satisfy the assumptions of Theorem U1. In addition, assume that each point of $I_F$ is regular for $\Omega$ and $F$ and that for each $R$ there is a continuous function $g_R: [0, \infty) \to [0, \infty)$ with $g_R(0) = 0$ such that

$$F(x,y,\lambda(x - y)) - F(y,u,\lambda(x - y)) \geq g_R(\lambda|x-y|^2 + |x-y|)$$

for $x, y \in \Omega, \lambda > 0$, and $|u| < R$. Let $u, v \in C(\Omega)$, $u$ be a viscosity solution of $F < 0$, $v$ be a viscosity solution of $F > 0$ and $u < v$ on $\partial \Omega \setminus I_F$. Then $u < v$ in $\Omega$.
Remark. The condition (1.20) on $F$ is a weakened version of a uniqueness condition used in [4]. The relevance of such a "one-sided" condition was pointed out by R. Jensen. See also [5] for uniqueness (in unbounded domains) and existence using this condition, as well as a generalization of it.

The proofs of Theorems U1 and U2 are, given Theorems 1 and 2, are routine and will not be given here. See, however, Jensen [7] concerning general formulations of results on closed sets.

Hamilton-Jacobi equations, viscosity solutions, uniqueness, boundary value problem, first-order nonlinear partial differential equations

At the classical level, when one considers boundary value problems for nonlinear scalar first order partial differential equations there are parts of the boundary where one does not expect to be able to prescribe boundary data. Likewise, uniqueness theorems can be proved for solutions which are prescribed only on parts of the boundary. However, globally defined classical
ABSTRACT (cont.)

solutions of first order nonlinear problems are rare, owing to the formation of "shocks". This theoretical difficulty has recently been overcome for equations of Hamilton-Jacobi type via the development of the theory of viscosity solutions, a sort of generalized solution for which good existence and uniqueness theorems hold. This note is concerned, in the context of viscosity solutions, with identifying parts of the boundary which are irrelevant for a given equation from the point of view of requiring data in order to prove uniqueness. This involves knowing when a viscosity solution of an equation (in the viscosity sense) in the interior of the domain may be extended by continuity to a solution in the viscosity sense to points on the boundary. The results obtained to this effect are supplemented by examples delimiting their sharpness.
