This report documents a computer-based gaming system for assessing recognition performance (RECOG). This was done so that others who may want to use it for either research, development, or operational implementation will have an easier time comprehending the modularity of the programming structure as well as how specific procedures can be adapted to suit a user's unique situation. The game management system is programmed in a modular manner to: instruct the student on how to play the game, retrieve and display individual images, keep track of how well individuals play and provide them feedback, and link these components by supervising routines inorder to execute the game. This modularity in programming, together with the game management system's independence of
Abstract continued

any graphic database (e.g., aircraft or ship silhouettes, human anatomy, topography, electronic circuits), contributes to its generalizability. The game, then, provides a set of software tools which can be used by others who want to assess recognition performance.

The software for the complete gaming system is currently on three floppy disks which control the play of the game, contain the graphic-images database, and maintain records of individuals' recognition performances. The game itself is run with two dual-density disks on the Terak microcomputer employing two drives. It is implemented on the UCSD P-System and written in UCSD PASCAL. The disk placed in drive 0, i.e., the 8510 or volume 4, holds the actual game code; the disk placed in drive 1, i.e., the 8515 or volume 5, contains the independent graphic-images database. As soon as the system is booted, control is immediately passed to the game. Consequently, naive users need not deal with the nuances of the UCSD P-System. Recognition-performance data are saved for a number of individual players on the 8510 disk drive. A third disk containing game management facilities can be used by test administrators or researchers to format the recognition data to facilitate statistical analyses. Also, this third disk can be used to design a new game with a completely different set of graphic images to act as stimuli for recognition testing.
FOREWORD

This programming effort was performed under exploratory development work unit RF63-522-801-013-03.04 (Testing Strategies for Operational Computer-Based Training) sponsored by the Chief of Naval Material (Office of Naval Technology). The objective of this work unit is to develop and evaluate microcomputer-based graphic simulations of operationally oriented tasks to determine if they result in better assessment of student performance than more customary measurement methods.

This program documentation is primarily intended for the Department of Defense training and testing research and development community.
SUMMARY

Background and Problem

The general goal of this exploratory development is to create and evaluate microcomputer-based graphic simulations of operationally oriented tasks to ascertain if they result in improved assessment of student performance when compared to more customary measurement methods. As a test bed, graphic models have been programmed to assess how well F-14 Pilots and Radar Intercept Officers (RIOs) recognize front-line Soviet and non-Soviet fighters and bombers.

A computer game based upon a sequential recognition paradigm has been designed and developed. It randomly selects and presents on the display of a microcomputer with millisecond speed either the front, side, or top views of four Russian bombers and ten of their advanced fighters. Also, the game management system can choose and flash corresponding silhouettes of NATO aircraft which act as distractors for their Soviet counterparts because of the high degree of similarity between them which could easily confuse U.S. air crews.

This game, which is called FLASH IVAN (aircraft images are "flashed" on the computer display, and the F-14 community refers to the Russians generically as "Ivan"), assesses student performance by measuring the number of correct recognitions out of a total of forty-two silhouettes (half Soviet and the other half non-Soviet), the time it takes a student (latency) to make a recognition judgment for each target or distractor aircraft, and the degree of confidence the student has in each of his/her recognition decisions. At the end of the game feedback is given to the student concerning his percentage of correct recognitions, average response latency, average degree of confidence in the recognition judgments, and how his performance compares to other students who have played the game.

A file is maintained and available to the instructors which provides, in addition to these parameters for each student, recognition performance across aircraft for all students who played the game. This provides diagnostic assessments to instructors who can use this information to focus student attention on learning the salient distinctive features of certain aircraft in order to improve their recognition performance.

The software for the complete gaming system is currently on three floppy disks which control the play of the game, contain the graphic-images database, and maintain records of individuals' recognition performances. The game itself is run with two dual-density disks on the Terak microcomputer employing two drives. It is implemented on the UCSD P-System and written in UCSD PASCAL. The disk placed in drive 0, i.e., the 8510 or volume 4, holds the actual game code; the disk placed in drive 1, i.e., the 8515 or volume 5, contains the independent graphic-images database. As soon as the system is booted, control is immediately passed to the game. Consequently, naive users need not deal with the nuances of the UCSD P-System. Recognition-performance data are saved for a number of individual players on the 8510 disk drive. A third diskette containing game management facilities can be used by test administrators or researchers to format the recognition data to facilitate statistical analyses. Also, this third diskette
can be used to design a new game with a completely different set of graphic images to act as stimuli for recognition testing.

**Objective**

The objective of this report is to document the program underlying the computer-based gaming system. This was done so that others who may want to use this set of software tools for either research, development, or operational implementation will have an easier time comprehending the modularity of the programming structure as well as how specific procedures can be adapted to suit a user's unique situation.

**Utility Functions**

This section of the documentation describes how to create new recognition games which would employ as subject-matter databases graphic images other than aircraft silhouettes currently used by Flash Ivan. It also explains how to extract statistical data for sample of subjects from records of recognition performances.

**Programmer's Notes**

This portion of the documentation serves as a technical reference for programmers who may want to make slight modifications to the game code itself which is independent of the database. It deals with several files and describes procedures which would be involved in performing these changes.

**Program Maintenance**

The final segment of the documentation explains how to maintain the program, the organization and the handling of the three disks that are used, and what to do to the disks before and after collecting recognition-performance data. A listing of the program is presented in Appendix A.

APPENDIX A: Program Listing .................................................. A-0
INTRODUCTION

Background and Problem:

Many student assessment procedures which are currently used in Navy training are not adequately accurate or consistent. This sometimes results in overtraining which increases costs needlessly, or undertraining which culminates in unqualified graduates being sent to the fleets.

Typical procedures for assessing performance do not adequately measure with sufficient fidelity, validity, and reliability real-world operationally oriented job-sample tasks. Consequently, student evaluation at its best is somewhat suspect, and decisions based upon this kind of assessment may be erroneous.

Better testing techniques are needed for assessing Navy trainees against performance standards employing tasks functionally similar to those encountered in operational contexts. One attempt to fulfill this requirement involves the use of microcomputer technology which is rapidly appearing in a number of Navy training and testing environments.

There is, however, no suitable knowledge base which can be tapped by the Navy (or others) for developing, evaluating, selecting, and using computer-based testing strategies incorporating graphic representations of job-sample tasks.

Many of these customary methods for measuring performance either on the job or in the classroom involve instruments which are primarily paper-and-pencil in nature, e.g., check lists, rating scales, critical incidences; and multiple-choice, completion, true-false, and matching formats.

A number of deficiencies exist with these traditional testing techniques, e.g.: (a) biased items are generated by different individuals, (b) item writing procedures are usually obscure, (c) there is a lack of objective standards for producing tests, (d) item content is not typically sampled in a systematic manner, and (e) there is usually a poor relationship between what is taught and test content.

What is required is a theoretically and empirically grounded technology of producing procedures for testing which will correct these faults. Very few data are presently available regarding the psychometric properties of testing strategies using microcomputer-based graphically represented simulations, models, or metaphors. Technical information is needed concerning the accuracy, consistency, sensitivity, and fidelity of these computer-based assessment schemes compared to more traditional testing techniques.

The objective of this exploratory development is to develop and evaluate microcomputer-based graphic representations of operationally oriented tasks to determine if they result in better assessment of student performance than more customary measurement methods. As a test-bed, microcomputer-based graphic models have been programmed to assess how well F-14 Pilots and Radar Intercept Officers (RIOs) recognize front-line Soviet and non-Soviet fighters and bombers.
Empirical and psychometric studies will be conducted to ascertain if this computer-based game provides better estimation of student recognition performance compared to more customary measurement methods, i.e., multiple-choice or completion formats. These distinct assessment strategies will be evaluated in terms of their relative reliability, validity, and fidelity.

**Objective**

The objective of this technical report is to document the programming effort expended to develop and evaluate this generalizable and transferable computer-based gaming system for assessing recognition performance. This was done so that others who may want to use this set of software tools for either research, development, or operational implementation will have an easier time comprehending the modularity of the programming structure as well as how specific procedures can be adapted to suit a user's unique situation.

In order to create a context to facilitate further the understanding of the documentation of this computer-based game, the on-line instructions, presented to student pilots and RIOs whose performance will be assessed, are as follows:

"For research purposes, a computer game called "FLASH IVAN" has been designed and developed to assess how well Navy Pilots and RIOs recognize front-line Soviet and non-Soviet fighters and bombers. This randomly selects and presents on the Terak screen with millisecond speed either the front, side, or top views of four Russian bombers and ten of their advanced fighters. Also, the game management system can choose and flash corresponding "fioettes" of NATO aircraft which act as distractors for the Soviet aircraft because of the high degree of similarity between them which could easily confuse U.S. aircrews.

"This game assesses student performance by measuring:

1. your "hit rate" or percentage of correct recognitions out of a total of eighty-four silhouettes (half Soviet and the other half non-Soviet),
2. the time it takes you or "latency" to make a recognition judgment for each target or distractor aircraft, and
3. your degree of confidence in each recognition decision.

"At the end of each trial, you will be given feedback in terms of: the correctness of your response; a running tally of the number of correct recognitions, your hit rate, average response latency, and average degree of confidence in recognition judgments up to this point. At the end of the game, you will be given how your performance compares to other students who have played.

"Next, six examples will be presented to familiarize you with how the game is played. Notice that a silhouette will flash on the screen. If you do not pay attention and concentrate on the center of the screen you will likely miss seeing it! Your task is to identify as quickly as you can the flashed aircraft. After the image disappears, you will see the prompt: "AIRCRAFT NAME:". Use the key board to type in after this prompt what you think the aircraft is, i.e., its NATO name or corresponding alphanumeric designation, e.g., SABER or F-86. Misspellings count as wrong responses."
as the ADMINISTRATION Disk.

Instructors, on the one hand, may want to create a new game with a completely different database than the original game, FLASH IVAN, which uses aircraft-silhouettes. There are two basic steps in undertaking this task:

1) the creation of the computer images, and

2) the corresponding database which associates labels with each image.

The user-friendly programs SEMIPAIN and MAKEDIR on the ADM disk were designed to aid an instructor in performing this task.

Researchers or evaluators, on the other hand, may wish to extract statistical data from the game. The program MAKESTATS has been designed for this purpose.

For the programmer who is enhancing the game to suit an instructor's needs, the ADM disk provides many basic utilities, e.g., PRINT programs and disk formatting programs, as aids. The actual game code, written in UCSD Pascal, also resides on the ADM disk. A programmer may want to change the code in making basic game changes. Of course, a basic familiarity with the UCSD P-system and UCSD Pascal (Bowles, 1977, Grogono, 1980; SoftTech, 1978) is prerequisite to successful completion of such a task.

The following sections give the details of the utility functions on the ADM disk. We have decided to approach the matter from the point of view of the user. Rather than describe each utility function separately, we have opted to group descriptions of the utilities together in the context of the two most important outcomes of their usage; hence, the two section headings:

1) Creating a Game

2) Using the Statistics Package

We recommend that you walk through the running program while simultaneously reading these sections.

2. Creating a Game

Two of the variable components that are the basis for a new game are:

1) the images, graphic representations, or pictures

2) the information associated with each image

This game-specific information is always contained on a disk which is separate from the game-code disk, and is to be placed in the top-disk drive during run time. Theoretically then, a new game can be played simply by putting a new disk
in the upper disk drive and rebooting. This new disk would contain a new set of graphics (called FOTOFILES) and new corresponding information (called an IMAGE DIRECTORY).

2.1. Creating Game Images

The task of creating graphics or images is certainly the bulk of the work load in creating a new game; it involves the meticulous recreation of drawings or their like into computer images. There are typically two ways of undertaking this task: by use of a digitizer or by hand using some sort of graphics editor.

Certainly the fastest and most convenient of these two methods is by use of a digitizer, a type of camera which has the capability to project any image that it can "see" onto the computer screen. However, we have yet to discover a digitizing system that is compatible with the TERAK microcomputer.

We resorted to the slower of method of converting each image by hand (see SEMIPAIN instructions for more details); however, any graphics editor that can work on the TERAK and create 320 x 240 pixel images should work fine. It is also important that the name of the file holding the image end in the suffix "FOTO". Any file ending in "FOTO" is called by convention a fotofile and generally corresponds to a 320 x 240 packed array of boolean. Each member in the array is stored in memory as a bit and corresponds to one pixel (or dot on the screen). We also recommend the use of a grid-system in converting technical drawings to computer image so as to maintain accuracy. By placing a piece of see-through graph paper over the drawing and a corresponding grid on the computer display, one can accurately translate the original figure to the screen.

In order to maximize the number of images that can be used in a game, we have given the game creator the option of dividing each 320 x 240 pixel fotofile into thirds. These thirds are referred to as the TOPTHIRD, MIDTHIRD, and BOTTHIRD and consist of 320 x 80 pixels. Thus, either 1, 2, or 3 images can be stored on one FOTOFILE; when an image is flashed to the screen it will automatically be centered. Several restrictions pertaining to gaming images to be wary of are:

1) a maximum of 89 images are allowed in the game

2) a maximum of 50 FOTOFILES are allowed on the upper disk

These restrictions have been imposed due to the limited storage capabilities of the TERAK microcomputers.
When all of the FOTOFILES for use in the game have been created, it is necessary to store them on one disk which must be FORMATed and ZEROed beforehand (see instructions for UCSD P-system). The disk must also hold, in addition to the game FOTOFILES, the following standard files that the prototype game needs to access:

EX1.FOTO
EX2.FOTO
EX3.FOTO
EX4.FOTO
EX5.FOTO
FLAGS.FOTO
EAGLE1.FOTO
EAGLE2.FOTO
IN1.FOTO
IN2.FOTO
INSTRUCT.TEXT — game instructions
NONE.FOTO

You must copy these files onto your disk. Two other files that you need not worry about, which will appear on your disk later are:

NEWNAMES — the Image Directory
HISCORE.DATA — keeps record of top ten players

2.2. Creating the Image Directory

Once all of the game images have been put on the special disk, it becomes necessary to create an Image Directory. The Image Directory is a list of 100 records that provide the main program with information concerning each visual stimulus in the game. Records 90-100 have been specifically reserved for system images. Records 1-89 are for your use, giving the main program information concerning game images. Each record contains:

a) two identification names associated with each image
b) the name of the fotofile which holds the image
c) where on the fotofile the image is stored

The program MAKEDIR has been especially designed in aiding the game creator in making an Image Directory. Before executing MAKEDIR, be sure the disk with the game fotofiles is in the upper disk drive. This action is necessary because the Image Directory also stores device-dependent information concerning where each FOTOFILE is on the disk, thus enabling the use of better and faster routines in projecting an image to the screen. In addition to this, the Image Directory, is stored on the images disk.
Upon executing MAKEDIR, the user will see the following menu:

**MAKEGAME OPTIONS:**
1) EDIT DIRECTORY  
2) CONVERT DIRECTORY  
3) QUICKLIST  
4) MAKE HISCORES FILE  
5) QUIT

Typing "1" will enable the user to begin creating an Image Directory for the first time or to edit a pre-existing Image Directory. The next prompt a user will encounter is:

```
Edit OLD file or make NEW file? [O/N] -->
```

Type "N" (meaning "NEW") to get the next prompt:

**EDITING OPTIONS:**
1) INDEX CHOICE  
2) AUTO-INDEX

The INDEX CHOICE option allows the user to edit any one record in the index range 1 to 100. This option becomes especially useful to a user who is making small changes to an OLD Image Directory. The AUTO_INDEX option, on the other hand, will automatically loop through a predefined sequence of records after the user is done editing a particular record. This option is especially applicable to the user who is creating a NEW directory. After typing "2" specifying the AUTO_INDEX option, the next prompt to appear will be:

```
Enter lower index bound, space, upper index bound
```

These bounds indicate the range of records you wish to edit. Needless to say, the lower index bound should be less than the upper index bound, and both bounds should be within the 1-100 range. More likely than not, you will not need to edit records 90-100; they have been preset and pertain to "system" images. Be wary that once you begin editing records in a certain range, you must complete the sequence if you wish the information to be recorded on the upper disk. Eighty-nine records are a lot of records to edit in one sitting. If you have a limited amount of time you may only want to edit records in sequences of 10. This method will also allow you the freedom to go back and repair minor mistakes you may have made with the INDEX CHOICE option (as opposed to having to go through all 89 records before coming back to repair mistakes). Once you have entered your index bounds, you will be presented with a menu which corresponds to one record in the Image Directory. The menu will appear as such:

```
INDEX NUMBER  n
Name 1: none123
Name 2: none123
```

8
Fotofilename: FLAGS.FOTO
Fullscreen [T/F]: TRUE
TopThird [T/F]: FALSE
MidThird [T/F]: FALSE
BotThird [T/F]: FALSE

Use the arrow keys on the right side of the keyboard to move among the choices. You will notice a small arrow on the left border of the menu specifying which item you are currently pointing to. Type "S" to select the item you wish to make changes to. For example, suppose the indicator arrow is pointing at "Name 1:". Typing "S" will provoke a new prompt occurring at the bottom of the screen:

Name 1 is currently "none123"
Enter the new Name 1: -->

After entering the new Name 1 followed by <RET>, you will notice the new prompt on the right hand side of the screen:

Change more values? [Y/N]

This same prompt will occur after any change that you make. A "Y" response will bring you back to the same indexed record. A "N" response will automatically project the next sequential record to the screen (provided you are in the AUTO-INDEXY mode). So when typing "N" be sure that you have entered in all of the correct information, because if you have make any mistakes and typed "N" going on to the next record, you won't be able to go back and correct the mistakes until you are done with the sequence of records. Suppose you were to type "Y", going back to the same record to edit. You select "Name 2:"; if there is no second name associated with your image, it is best to enter an empty string by simply hitting <RET> when prompted for "Name 2:"; otherwise, if a game player were to respond incorrectly to this game image, the name "none123" would appear under "the correct name is:" heading.

In selecting "Fotofile name:" , you will notice that it has been preset with the name FLAGS.FOTO. This acts as a default file which will be flashed to the screen if you happened to have forgotten to type in a fotofile name. When you enter the fotofile name, be sure to include the "FOTO" suffix. All fotofiles are assumed to be in the top drive so the prefix "#5:" is unnecessary.

The remaining four fields of the record indicate where the image is stored on the fotofile. For instance, if "Fullscreen" were set to "TRUE", then image is contained on a complete fotofile; and conversely, it would be set "FALSE" if it was not contained on a complete fotofile. Note that more the one of these fields could not possibly be set "true" at the same time; in other words, an image could not possibly occupy a full fotofile and a third of a fotofile simultaneously. So as soon as one of these items is selected, it is automatically set to "TRUE" while the remaining items are set to "FALSE".
Whenever you are done editing after either completing a AUTO INDEX sequence or responding "N" to the prompt "Another?" in INDEX-CHOICE, the screen will clear and the computer will inform you that it is "converting" the directory, before taking you back to the main menu. During "converting" if any of the fotofiles that you listed under "Fotofile name:" are not on the images disk, you will get a message notifying you of this. This function is described in more detail below.

2.3. More Utilities

After Editing an Image Directory, or whenever running the utilities program MAKEDIR, the user will always be presented with the main prompt:

MAKEGAME OPTIONS:
1) EDIT DIRECTORY
2) CONVERT DIRECTORY
3) QUICKLIST
4) MAKE HISCORES FILE
5) QUIT

We have already discussed option #1 concerning Editing a directory. The following paragraphs discuss the remaining options.

2.3.1. Converting the Directory

Typing "2" from the main prompt line will run code that "converts" an Image Directory. Converting a directory is processed on the top disk which translates fotofile names into numbers which describe where a fotofile is on disk. This number (referred to as the BLOCK number) is stored in a "hidden" field in each record of the Image Directory; its main function is to speed up the time it takes to access an image from disk and flash it to the screen during game time. When it has finished, image directories ("NEWNAMES") will be written to both the upper and lower disks.

Whenever any disk operations (ADDing a file, DELETING a file, KRUNCH- ing the disk, etc.) are performed on the images disk, the P-system file system usually rearranges the placement of files on a disk; thus Converting the disk is essential in these instances so as to assign new BLOCK numbers to Fotofiles. If ever you come across a bizarre collage of images flashed to the screen during game time, it has probably resulted from your forgetting to "Convert" the Image Directory.

Note that it is unnecessary to select the CONVERT option if you are editing an Image Directory since the EDITING option automatically converts the disk for you. Also, if ever you entered a fotofile name that is not on the images disk,
the Conversion function will send a message to the screen indicating this.

2.3.2. Quicklist

Typing "3" from the main menu will automate the QUICKLIST function. This is a convenient way to quickly look over every record in the Image Directory. As each record is scrolled down the screen, you will notice the addition of the aforementioned "hidden" field labelled BLOCK included in each record listing. The entire list of 100 records in the Image Directory will be sent to the screen, and then to a file "QUICKLIST.TEXT" on the disk in the bottom disk drive. This list can then be sent to the line printer for further scrutiny using the PRINT program.

2.3.3. Making the Hiscores File

"Make Hiscores File" will create a new HISCORE.DATA file which will prompt you for the top ten players (we have used fictional people) and their respective scores. When entering in the new list, it is not necessary to list players and scores in any special order. The program will automatically list them from top to bottom in descending order according to score. The current version of the game maps scores in the 0 - 1000 range, so it is best to enter scores in this range.

3. Using the Statistical Facilities

MAKESTATS is a program which takes the data from the computer recognition game and formats it into a text file so that it can be viewed or sent to a printer. In order for it to operate correctly it must have two important files on the same disk (i.e. the "ADM" disk):

NEWNAMES
GAMES.DATA

NEWNAMES, the image directory, is needed so as to associate image names with statistics. GAMES.DATA, a record file, holds the game stats and consists of the record type "gamestats":

11
const numberpictures = 89;
type GAMESTATS = record
    name : nametype;
    SS   : sstype;
    date : nametype;
    latency : array[1..numberpictures] of integer;
    confidence : array[1..numberpictures] of scale;
    correct : array[1..numberpictures] of boolean;
end;
type nametype = string[15];
sstype = string[11];

The constant NUMBERPICTURES is set to the number of total possible images which can be shown in the game, not the actual number used in each game. Makestats is set up so that any number of graphic stimuli can be used (up to the maximum) in a game. Only those actual photos used in each game are tallied for averages over several games. Records of type GAMESTATS keep statistics for each game and when it is through, and are saved in a disk file, GAMES.DATA. Recorded for each game are:

name: The player's name, up to 15 letters;
ss: The player's Social Security number, any string up to 11 characters is allowed so that errors can be avoided when non-numeric data is entered;
date: And likewise, a 15-character length string for the date the game is played is kept;
latency: The player's response latency is kept for every image he responds to, if an image is not used in the game then the latency will be 0;
confidence: And similarly, the player's confidence rating which he has keyed in for every image;
correct: Whether the player actually got the image recognition correct or not.

After a game is completed, a variable CURRENTGAME of type GAMESTATS is appended onto GAMES.DATA.

When Makestats is executed, GAMES.DATA is opened and each game that has been saved is read one at a time. They are then neatly formatted and put into two textfiles on disk: LATENCY.TEXT and CONFIDENCE.TEXT. Latency.text will include vertical and horizontal averages of the response latencies. That is, each player's average response latency over one game, and the average response latency for each photo over all the games recorded. Confidence.text includes the same thing for the confidence ratings and averages,
but the correctness ratings are also included; a "+" is put before the confidence rating if the player got the recognition correct, otherwise a "-" if he got it wrong. Also, in the formatted output are included the percentage of graphic stimuli the player correctly recognized in each game and the percentage of games which got any certain photo right.

As makestats is executed, the old data in GAMES.DATA is erased, and a new GAMES.DATA is initialized with 0 game entries. In order for the game to save statistics properly, GAMES.DATA MUST be the LAST file on the disk's directory. Otherwise, the file will get too large, there will be an I/O error, and the game will not be saved. If the error message appears:

i/o error: no room on volume

Then you must:
1) Delete GAMES.DATA from the disk,
2) K)runch the disk in the Filer,
3) eXecute DRIVER.

DRIVER is an executable file which initializes an empty GAMES.DATA file on the disk in the upper disk drive.

The text files LATENCY.TEXTURE and CONFIDENCE.TEXTURE have cross-references to index planes and players. This is a sample LATENCY.TEXTURE prin-tout:
The players are indexed by capital letters AA, AB, AC, ..., BA, BB, ..., ZZ and later are cross-referenced with their name and Social Security number, the date of the game, and their average response latency (or average confidence and percentage correct as in CONFIDENCE.TEXT). The images are indexed with numbers 1, 2, 3... across in rows of 12 so that it is feasible to put all the data on one page. At the end the planes are cross-referenced to the viewing angle (top, front, or side), the plane name, and the average response latency scored on that plane for ALL the games using that graphic image. The same pertains to the average confidence and percentage correct for ALL the games using that picture, for CONFIDENCE.TEXT.
PROGRAMMER'S NOTES --Modifying the Game Code

4. Introduction

This section of the documentation is designed to serve as a technical reference for programmers who may wish to make slight modifications to the game code itself which is independent of the database. We have divided it into four main sections:

1. Overview --an introduction and reference guide to making changes
2. The File G/.IVAN --technical descriptions of procedures
3. The File GAMEUN3 --technical descriptions of procedures
4. The File ITEMFILER3 --technical descriptions of procedures

5. Overview

The computer-based recognition game in its present form, Flash Ivan, is currently implemented on the UCSD p-system, version II.0. It is run on a Terak 8510 dual-density machine, with an auxiliary 8515 dual-density drive. The game requires two disks, the bottom (#4:) drive gets the disk with the actual program (named System.startup-- a program that automatically runs when the disk is inserted), while the top (#5:) drive gets the disk with the database, described in the section on ItemFiler3.

This particular implementation of the game consists of aircraft silhouettes, but it could be used for any set of graphic images that could be drawn into the database (see the Utilities documentation), and used in a recognition-game format. Because of this, we may refer to "planes", "airplanes", "pictures", "images", "visual stimuli", "graphics", or "database objects". All of these refer to the same thing.

5.1. The Files

The Flash Ivan game code consists of the following files:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>G/.IVAN</td>
<td>Pascal host program</td>
</tr>
<tr>
<td>GAMEUN3</td>
<td>Pascal library file</td>
</tr>
<tr>
<td>ITEMFILER3</td>
<td>Pascal library file</td>
</tr>
<tr>
<td>ERROR</td>
<td>Assembler code for sounds</td>
</tr>
<tr>
<td>CLICK2</td>
<td>Assembler code for sounds</td>
</tr>
<tr>
<td>TIMEPI</td>
<td>Assembler code for sounds</td>
</tr>
</tbody>
</table>

The code was split into separate files to make manageable segments, without much effort being made toward extreme modular cohesiveness. The host file, G/.IVAN, contains the main driving routine, and several assorted procedures and functions. The file GAMEUN3 contains more assorted procedures and functions, as well as a few constant declarations for good measure. The most cohesive file, ITEMFILER3, contains procedures dealing with the database, some constant declarations, and the HI-SCORES procedure. There are also some separate assembly language routines that need to be linked: ERROR, TIMEPI, and
5.2. An Important Global Variable

The variable Info_List, declared in the file ItemFiler3, is an array with one element for each item in the database. Each element in the array contains information on what the airplane's different names are, and how to get it from the disk and show it on the screen. This is, in some sense, the "master variable" of the game. It allows most of the game procedures to think of the planes only in terms of indices into the array, and allow a couple of interfaces (the procedure CheckAnswer, the functions in the file ItemFiler3) to actually deal with the other information.

5.3. Making Changes

For programmers who plan on making any changes to these files, we recommend using the ensuing FLASH IVAN technical descriptions as a reference. Before relinking any freshly compiled files (listed above), please be sure the compilation dates as listed from the Filer are consistent. If the dates are not the same on any two files, linking errors will result. To change the date on any file, you must first change the date for the disk (Date option in the Filer) and then recompile or reassemble the file.

5.4. Relinking

When linking, remember that "G/IVAN" should be typed in as response to the prompt "Host?". For the sequence of prompts "Lib file?", the other files listed above (as well as "*" for the System.library) should be included. For the prompt "Output file?", be sure to add the ".CODE" suffix so that it will be executable. On the official game disks, we often moved our executable game file into the file System.startup; thus upon booting, control is immediately passed to the game. In this way, naive game players need not deal with the particularities of the P-System.

5.5. Transportability

Flash Ivan is designed to run on any computer with at least 128K RAM that supports the UCSD P-system. However, if Flash Ivan is to be run on any machine other than the Terak, slight modifications must be made to the game code. As a rule of thumb, it is safe to assume that any code having to do with device-dependent graphics or sound manipulations will have to be rewritten. To make the game code as transportable as possible we have attempted to localize most of the machine dependent code in the file ITEMFILER3. Modifications must be made here. ITEMFILER3 serves as a home for the majority of the graphics code.

---

* We consider the database to contain all the information about the pictures, plus the pictures themselves. The top disk (#5:) contains the database.
5.6. Secret Codes

After having made any changes to some of the Pascal files, we suggest that you record the latest date of change in the string constants at the top of each file, DateMain, DateGameUn3, or DateItemFiler3. These three dates can be displayed from the linked and running version of the game by typing in a secret code word at the start of any game (see the function Practice in the file G/.IVAN. With so many different files and so many different disks, as well as several programmers, we found that this facility helped us organize ourselves as well as see what version of the game we were actually playing.

In addition to seeing what version of the game you have, there are other functions you can invoke from the start of the game. Upon seeing the prompt "HIT RETURN TO BEGIN GAME" just above the Eagle's head, you can access the "version" function as well as a few other helpful ones. The code characters and their corresponding functions are listed below:

- `<esc>` -- to bypass instructions and examples
- "v" -- to list versions of Pascal host and objects
- "m" -- to see memory available. We were pushing the upper limits of RAM when this documentation was written, so this function came in handy. Be wary if you plan to make any major additions.
- "d" -- to display any pictures from the image directory
  The image directory is an array of 100 records containing graphical information on each game image. Entering numbers between 1-100 is advised here. If any images are centered incorrectly or the wrong picture is displayed, it is likely that the image directory needs to be "converted", or bad information was put in the image directory by a game maker. Consult the "Flash Ivan Utilities" Documentation.
- "h" -- to view the HISCORES file

These characters can entered in either upper or lower case. One version of the game requires you to hit the password "boatman" from the main prompt in order to access any of these functions. This prompt must be lower case. Since the Terak is initialized to an "all-cap" status, you need to know how to get to an "upper/lower case" status. The <DC2> key at the lower right of the keyboard provides the function of toggling between these two keyboard states. See the procedure Practice in the file G/.IVAN for more details.

6. The File G/.IVAN

G/.ivan is a file that contains the main body of the game program. It makes calls to other procedures defined in library files so as to provide a cohesive unit among all of the game files.
6.1. Constants in G/.IVAN

There are three constants defined in this file. It is arguable whether or not the constant declarations should be here instead of in one of the units with the other constants, but they are only used here, so there is some justification.

**name:** This is set to the filename where the statistics will be collected.

**PRACSTART:** This is set to the beginning index of the practice pictures. In our implementation, the actual game pictures go from 1 to 84. Practice pictures then start at 88. 85 is a "delimiting" entry. (See the section on ItemFilerS for an explanation of the database, indexing, etc.)

**numberpictures :** This tells the statistics functions how many different test items there are. Statistics will be printed for items one through numberpictures. (See the MakeStats subsection of Utilities for more on the statistics functions.)

**DateMain:** This is for programming convenience. It is a string constant set to the date and time the file G/.Ivan is modified. The "v option at the beginning of the game will print out this constant, as well as similar ones in GameUns, and Itemfilers.

6.2. The Program Run

The "main" procedure of the program is fairly small (about ten lines), and is run through only once per game. Calls are made to procedures to initialize the statistics variables and database list (Info_List), and show the opening animation. Then the variable TotalPictures is set to forty-two. This is a number particular to this game, and means that only forty-two of the total of eighty-four pictures will be included in any one game. For a game to include the entire set of pictures, a call to the function ListLength with the parameter Info_List to set TotalPictures could be made instead.

Next, the procedure ChoosePlanes is called, with PicSequence as its parameter. PicSequence is an array of integers, declared in GameUn3. The integers it will contain correspond to database indices, one for each picture contained there. The ChoosePlane procedure is another that is specific to the database, and particular game demands of FlashIvan. It will pick seven Soviet top views, the seven corresponding NATO distractor top views; seven Soviet sides, the corresponding NATO side view distractors; and seven Soviet front views and their distractors for a total of forty-two aircraft images. This is out of a possible eighty-four silhouettes. They will not be randomly ordered, but each set of seven will be randomly chosen from fourteen possible images.
In order to present the pictures in a random order, the procedure *Shuffle* is
next called, with reference parameter *PicSequence*, and value parameter *Total-
Pictures* to tell how many to shuffle. *PicSequence* will return with the same set
of picture indices, but in a new, shuffled order.

The procedure *PrivacyAct* shows two fotofiles which contain the necessary
text explaining to the research subjects, who are about to play the game, that
they are asked to not only identify themselves but also give their social security
numbers to facilitate statistical analyses involved in evaluating this computer-

The practice procedure first shows three examples, animating or mimicking

Hello will prompt for and read the player's social security number, name,
and date. It will then re-display the information and ask for confirmation. The
player is allowed to re-enter information until he is satisfied with it.

The *Practice* procedure first shows three examples, animating or mimicking

InitStat initializes the statistics variables. For a more detailed description,
see below.

The procedure *Game2* is the major game-playing loop which presents the
player with the full set of images (whatever the variable *TotalPictures*, which
resides in the file GameUn3, says) and keep track of all the game information.

The procedure *AfterGame* will write the information for the game just
played to the disk under the subject's name. It will then show the player's final
score, and call *HiScores* to show the current top-ten players.

6.3. The procedures in G/.IVAN

Due to the space limitations of the Terak 8510 computers, we had to make
as many procedures as possible "Segment" procedures. That is, they will only be
loaded into memory when needed, and then moved back out leaving room for
others.
6.3.1. Player Orientation Procedures

These are the procedures that are used in the beginning of the game to acquaint the user with the rules, and allow him/her to get familiar with the flow of the game by watching and playing some practice examples.

Procedure PaintBlock(VAR Source, Srcwid, Srcz, Srcy, integer; VAR Dest; Dstwid, Dstz, Dstx, Doxy, Cntz, Cnty, Mode, Gray: integer);

This externally assembled file is located in the System.Library, and can thus be accessed upon linking to the System.Library. PaintBlock simply copies bit maps from "Source" (a boolean array) to "Dest" (another boolean array). "Cntx" and "Cnty" are the width and height of the block of the boolean array to be copied. The "Mode" parameter gives the following boolean operations: 0 = store, 1 = or, 2 = and, 3 = xor, 4 = complement. The "Gray" mode seems to work best set to -1.

Procedures Click2, Timepi, Error;

These procedures are external MACRO-11 assembly procedures used for various game sound effects. For assembly code alterations, refer to the UCSD Pascal User's Manual (SoFtech), or your favorite MACRO-11 (PDP-11 Assembly Language) handbook. Essentially, all the sound effects are produced by switching bit 7 of the VCR (Video Control Register) at various frequencies. The include file SND_EFF.TEXT is inserted at the beginnin of each of the three assembly procedures and contains two simple MACRO algorithms for switching the VCR.

If one is interested in creating or adapting some new sounds, methodical experimentation with with these macros is suggested.

IMPORTANT: When linking assembled procedures to Pascal host programs, make certain that all file dates (including the include files) are the same. If they are not dated similarly, the Linker reports a diagnostic such as "Click2.code not found"

In addition, all assembled procedures must NOT be linked to the System.Library before linking to the Pascal host; the respective code file will also be reported "Not Found" by the Linker.

Procedure Animate;

This Pascal procedure's two main purposes are to initialize the boolean array used for graphics, and to perform the opening animation sequence at the beginning of each program run.

Animate first initializes the two global boolean arrays Minifoto and Crosshairs to contain their bit-map icons for the duration of the game. Minifoto contains the labels "AIRCRAFT:" and "% CONFIDENCE" as well as the Confidence ruler "TAB ... 0"; CROSSHAIRS contains the gun sight icon that is always flashed to the screen a split second before an actual game recognition
image (see procedure Display). Both arrays, Minifoto and Crosshairs, are initialized by a disk read from a FOTOFILE indexed "91" in Info_list to the Screen buffer, followed by two calls to PaintBlock copying both bit-map arrays from Screen.

After these initializations, the Eagle animation code follows. The animation is the simple "flip-book" approach centered upon the Eagle's head; it is accomplished by a series of calls to PaintBlock with an interspersed call to the sound effects procedure TimePi. Notice that each call to PaintBlock is followed by a call to UnitWrite(S, Screen, 69) so that the screen is updated for each animation "frame".

Procedure Instruct;

Instruct is the first nested procedure in Practice. Its primary function is to read the contents of the file Instruct.Text (the game instructions) from the upper disk drive. You may notice that whenever game-specific information is read into the game (such as reading in the main game array Info_list, the game instructions, or the FotoFiles) they are always read in from the upper disk (#5:). We implemented this standard in our game to make it flexible to new games. Instruct reads in one string at a time from the text file, and then outputs each line to the screen one at a time. This type of implementation prevented us from having to read in the whole textfile, thus saving valuable memory space needed for game code. After 21 lines have been projected to the CRT, no more lines are read from the file until the game player hits the <RET> key.

Procedure Play$;

Play$ simulates three game examples exactly as they would appear in the game. The variable ListIndex is set to 95, 96, and 97 in a loop. These numbers correspond to the practice game images' indices in the main game array Info_list. Records 90-100 in Info_list have been reserved for such purposes as storing information pertaining to these practice game images and other system images such as those used in the opening Eagle animation. The calls to Display and SingleTrial flash the image to screen, prompt the player for a response, collect statistics, and display the results. These 2 calls are the very calls used in the actual game as well. The additional variable FakeList is used in this procedure to hide the fact that list indices > 90 are being displayed. Single_Trial only expects to be called with numbers less than 90, the total amount that can be used in a game. Throughout the Practice module, FakeList is set between 1 and 6, so that statistics can tabulated for six examples. These "fake" statistics stored in the scorefile are overwritten during the first 6 loops through SingleTrial during the actual game (see Procedure Game2).
Procedure Answer(VAR A1: string; X, Conf: integer);

This procedure is used in looping through the 3 automated examples in Practice; it attempts to simulate SingleTrial by displaying prompts, collecting statistics, and displaying results. In addition to this, Answer also simulates a player, by supplying the responses (A1) as well. X is the number of characters in the string A1; between each character being output to the CRT, ClickE is called to simulate the sound of the keyboard. Conf is the confidence integer to be recorded in the statistics.

Procedure Practice; (main block)

This is the main procedure for providing game players practice with game examples; it makes calls to the aforementioned procedures which are nested in Practice: Instruct, Play8, and, Answer. Notice that this procedure can be immediately exited with the entry of a password from the standard input, when the prompt to "hit <ret>" comes up. This drops the program into a loop where a response of <esc> to the new prompt initiates the game, bypassing instructions and examples. We implemented this "secret" option, so as not to needlessly walk players who know the game sufficiently well through the instructions and examples. There are also four other options at this point. The user could type the character "H" (upper or lower case) to see the Hi-Scores board, "V" to see the versions of the three game files (the constants defined in each file--DateMain, DateGameUn8, DateItemFiler9), "M" to see memory available (via calls to the provided function MemAvail), or "D" to display any pictures from the database. For this option, the user will be prompted for the index number of the picture to display. (Note: this option is not currently implemented.) This is all put into a loop, so whenever the prompt to "hit <ret>" comes up, the user can continually hit the character options instead. The loop drops through when either the return key or the escape key is hit.

Notice that FakeList has been initialized here before going through the 6 game examples. FakeList is used as a dummy index so as to keep statistics during the practice run. These statistics will be overwritten and forgotten during the real game run. After this initialization, the automated examples are then created with 3 calls to Display and Answer. Notice that indices 92, 93, and 94 are used here. These integers correspond to the game example information stored in InfoList. Play8, the participatory examples, is then called; it uses InfoList indices 95, 96, and 97.

Procedure PrivacyAct;

For the instructions, this simply opens the file "#5:Instruct.text" and reads one line at a time, then writes that line to the screen. Every 21 lines, the "write a line" loop stops, writes "hit <RETURN>", and waits for the return key to be hit with a "readln()" statement.

22
The text of the privacy act has been typed in to two fotofiles. To show these, it does a UnitRead of the fotofile from the disk, and a UnitWrite to the screen.

Procedure Hello(VAR player: nametype; VAR date: nametype; VAR SS: estype);

The procedure Hello prompts the player for his name and the date, both of which are of type NameType, a string of 16 characters in length; and also for his Social Security Number, of estype, a string 11 characters long. All three are stored at the head of the game statistics file GameStat, right before the arrays which store response latency, correctness, and confidence. The PrivacyAct function is also called in Hello and the prompts to start playing the game are printed out.

6.3.2. Other Procedures in G/.IVAN

Procedure Aftergame;

This procedure saves the GameStat file on the end of the Games.data file on disk when the game is over. It also prints out the player’s final score and calls OutputStats; and also calls HighScore.

Procedure OutputStats;

This procedure prints out for the user his/her percentage correct recognitions, average recognition confidence, and average response latency.

Procedure Initiate;

This procedure just initializes all of the arrays and variables used within the statistics portion of the program, invariably to 0.

Procedure AfterPicture;

This procedure puts the player’s response latency, confidence, and correctness in the proper spot in the GAMESTATS statistics file, and keeps track of various variables, such as how many planes have been shown, which are used to output statistics to the player.

Procedure GetConfidence(VAR conf: integer);

This procedure displays the confidence-rating continuum or scale and prompt via the calls to PaintBlock, and a couple of "write" statements. It then reads the player’s response as a character. If the character is not either a TAB,
or a digit, then the user will be asked to try again. Once a valid character is entered, it is converted to an integer value, percentage of confidence in the recognition judgment. For TAB, the confidence is returned as 0%. A zero keyed in corresponds to 100%. All other digits are 100 times their value. This is reflected in the recognition-response confidence-rating continuum.

Procedure SingleTrial(ListIndex: integer; ifprac: boolean);

The SingleTrial procedure times the player’s response, checks the answer for correctness, and calls the appropriate statistics routines to keep track of the player’s scoring. It is called from GameUn just after a picture has been shown. The parameter ListIndex is the index into InfoList for the picture just shown. It needs this to be able to look-up information in InfoList about that particular picture. The other parameter, ifprac, tells the function whether or not to look at the practice set of pictures (starting at InfoList[PRACSTART]), instead of the "real" set of pictures. This is needed because the practice procedures at the beginning of the game also need to call SingleTrial, but with a completely different set of pictures.

The delay loop:

\[
\text{for } i := 1 \text{ to SetSpeed do } \text{DELAY}(250);
\]

determines how long the picture will remain on the screen. SetSpeed is a constant, defined in GameUn. It allows coarse control over the delay amount (the DELAY() procedure delays for approximately one one-hundredth of its parameter: thus a change in SetSpeed of one results in a delay change of about 2.5 seconds). When the delay loop is through, the page(output) command will clear the picture. Then a prompt is shown, and the player’s response is read into the string guess. Ticks will then contain the number of "machine ticks"* that occurred between the disappearance of the picture, and the typing of the second key by the game player. This approach was chosen to in an attempt to not penalize poor typists, yet still get some measure of the player’s response time.

The calls to AfterPicture and OutputStat take care of updating the statistics, and showing the player his current performance information. After this is printed out, the player is given a chance to see the picture again, and look at it for as long as he wants.

The section of code at the end, currently commented out, will allow only a ten second pause after the end of the current trial. If the player does not type the <return> key before ten seconds are up, the game will write a message to the screen telling the player to pay attention, then the game will continue. As it is now, the game is set-up to remain in a wait-state if the return key is not hit.

\*\(\text{ticks/80) times 1000 equals the time in milliseconds.}\)
Procedure Game2;

This procedure is called Game2 for traditional reasons (once upon a time there was a Game1...). As mentioned earlier, this is the major game-playing loop in the program. It loops from 1 to TotalPictures, a variable set in the main program body. In our implementation, we set it to 42, so we always get a game of 42 trials. The loop counter is used to index into PicSequence, a previously loaded array of integers which are in turn passed one at a time to SingleTrial and used as indices into InfoList. These integers are unique, range from 1 to the highest possible game picture, and have been chosen and shuffled in main.

7. The File GameUn3

The file GameUn3 serves as a home to many of the assorted functions needed for the program. It is not a cohesive module in the software engineering sense. Only ItemFiler3 approaches that.

7.1. Constants

The same comments about the constants in G/Ivan hold here, also.

DateGameUn3 : This is a string telling when the file was last updated. See the constant DateMain in the section G/Ivan.

MaxInt : This represents the largest positive integer that the Terak can hold. This is why there is a limit to the reported latency of MaxInt milliseconds, or about thirty-two seconds.

SetSpeed : This is used to roughly effect the amount of time each picture is shown. A larger number will show the picture for a longer amount of time. It is used in SingleTrial.

ChooseGame, All_In_One, FlashGame :

These are all booleans which are supposed to allow different game setups. At this time, none of this is implemented.

7.2. Procedures in GameUn3

Procedure Randomize(VAR seed: integer);

This is an external function, found in the supplied System.Library, which fills the integer seed with a number derived from the system clock.
Function Random(VAR seed: integer; Low, High: integer): integer;

This random function returns an integer between (and including) the two bounds Low and High, and changes seed as well. This function is derived from information given in the book "Fortran 77 - Principles of Programming" by Jerrold L. Wagener, in chapter 8. Random has a period of 1024 (meaning the sequence of numbers generated will not repeat until 1024 calls have been made), and is designed for a machine with 16 bit integers.

The procedure was tested for approximating random selections by choosing 7 items from a possible 14. The results were tabulated, and the selection was done repeatedly. This test was done 10,000 times. The results follow:

<table>
<thead>
<tr>
<th>item number</th>
<th>how many times chosen</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4748</td>
</tr>
<tr>
<td>2</td>
<td>5463</td>
</tr>
<tr>
<td>3</td>
<td>5422</td>
</tr>
<tr>
<td>4</td>
<td>5092</td>
</tr>
<tr>
<td>5</td>
<td>4712</td>
</tr>
<tr>
<td>6</td>
<td>5220</td>
</tr>
<tr>
<td>7</td>
<td>4963</td>
</tr>
<tr>
<td>8</td>
<td>4297</td>
</tr>
<tr>
<td>9</td>
<td>5758</td>
</tr>
<tr>
<td>10</td>
<td>4773</td>
</tr>
<tr>
<td>11</td>
<td>4793</td>
</tr>
<tr>
<td>12</td>
<td>4928</td>
</tr>
<tr>
<td>13</td>
<td>4841</td>
</tr>
<tr>
<td>14</td>
<td>4990</td>
</tr>
</tbody>
</table>

These findings indicated that the pseudorandom number generator did indeed approximate random selections. The expectation of each item number for 10,000 trials is 5,000 which was approached by how many times each item number was chosen by the generator.

Procedure Shuffle(VAR IndexArray: IndexList; Num_of_Pics: integer);

The input reference parameter IndexArray is a set of indices into InfoList, previously chosen, but not necessarily in a mixed order. Shuffle will randomly choose 200 pairs of indices into IndexArray, and then exchange their contents. After Shuffle is called, sequential accesses into IndexArray will yield a random sequence of the original set of numbers.

Procedure MakeSequence(VAR IndexArray: IndexList; Num_of_Pics: integer);

This procedure is not currently used in our set up, but is more general than the procedure we use to make a game sequence (ChoosePlanets). After a call to MakeSequence(), the parameter passed in as IndexArray will contain a random
sequence of integers from 1 to whatever was passed into the second parameter (Num_of_Pics), each integer appearing once. This is useful for games where one game consists of each and every picture showing up once and only once. MakeSequence calls Shuffle to actually do the mixing.

Procedure ChoosePlanes(VAR IndexArray: IndexList; Num_of_Pics: integer);

This is a more complicated procedure for composing a set of silhouettes or pictures for an instance of a game. For Flash-Ivan, we had a total of 14 Soviet aircraft, each with a top, a side, and a front view. For each of the total 42 (14 times 3) Soviet pictures, we also had a corresponding NATO picture. We chose this picture to look as similar to the Soviet one as possible, to act as a "distractor".

We wanted this game to show 42 silhouettes in an unpredictable order. These 42 images should include equal numbers of fronts, sides, and tops, and equal numbers of Soviet and Non-Soviet aircraft. Further, for each Soviet silhouette shown, its matching distractor should also be shown sometime during the game.

ChoosePlanes relies on a special ordering of Info_List (corresponding to the ordering in the database). There should be 14 Soviet planes of one view (items 1 through 14), then the 14 distractors for those pictures in the same order (15 through 29), then 14 Soviet planes of another view, etc. This makes the relation between any picture and its distractor very simple. Just add 14.

ChoosePlanes has three sections. Each section chooses the fourteen pictures for one view. The sections are the same, except that different bounds are passed to random to reflect the new set of pictures to choose from, and each section fills a different piece of the array parameter IndexArray. Each section itself is a seven-iteration "for" loop. Each iteration chooses two pictures: a Soviet and a distractor. The Soviet picture is chosen by the random procedure in the specified bounds, then the distractor is found by adding fourteen. These two numbers are stored in IndexArray at consecutive locations.

One possible problem is that the random function could happen to return a number that it has already chosen. To take care of this, we declare a set of integers, AlreadyChosen, which is checked each time a new number is generated. If the new number is not in the set, then it is put into the set and the procedure goes on as described above. If the new number is in the set, then a loop is started. This loop generates a new number in the same bounds, and checks again. It continues until it finds a number not yet chosen. Although this method has the possibility (very slim) of continually choosing numbers already chosen forever, it was found that the time it actually took was never noticeable.
Procedure UpperCase(VAR Name1: string);

This procedure checks each character of Name1 and, if it is a lower-case alphabetic character ('a' through 'z') it converts it to its upper-case representation by subtracting decimal 32 from its ordinal value. This procedure works assuming an ASCII character set.

Function Compare(VAR first, second: string): boolean;

This function converts the two input strings to upper-case, then compares them, returning true if they are the same, false otherwise. The caller of this function should note that the strings are passed by reference, so they will be permanently capitalized.

Procedure NewLines(count: integer);

This simple procedure iterates a loop count times, calling a writeln each time to print out a new blank line.

Procedure ModWait(seed: integer);

This function is used to give a pseudo-random short delay. The input integer seed, presumably something from a random generator, is put into the range 0 to 200 with a call to mod, (this is the reason for the function's name), and then a do-nothing for loop is executed as many times as the result to give the short delay. One use of this is when we need to get two random numbers at the same time. The first call to random will read the system clock, and since the call takes a constant amount of time, the next call to random will always return a number with the same relation to the first. If we call ModWait(seed) in between, then the first number will have some sort of randomizing effect on the choosing of the second one.

Function ListLength(List: IList): integer;

This function finds the length of a partially or fully filled variable of type IList. It simply steps through the list until it finds an entry where the name field has either "none123", NONE123", or None123". This is our pre-defined stopper value, and is put into the database.

Procedure BuildString(VAR FinalString: string; NewChar: char);

This procedure is used to build up a string one character at a time. It is used in TimeRead, where we have to convert a stream of incoming variables of type char to one string. It is called once for each new character. The string being built is passed into FinalString, and the new character to be appended to the end is passed into NewChar. This procedure allows the backspace key to be
used as normal. It will delete one character off the end, and will write out the backspace to the screen.

Function *TimeRead*(VAR result: string): integer;

This is used to simulate a Pascal *readln*, to be used where some indication of the player's response time is needed. *TimeRead* reads input as a stream of characters, passing them one at a time to *BuildString* with parameter *result*. This means that at the end of execution of *TimeRead*, the reference parameter *result* will contain the entire string.

When *TimeRead* is first called, the internal clock is read with a call to the library function *Time*. At *EOLN* (end of line), or after two characters have been typed, the time is again read. The difference *LowStop - LowStart* is the number of clock-ticks it took to type two characters, or to type the Return key. The high-order bits of the clock, *HighStart* and *HighStop* are ignored here.

It was found that once in a while the clock would start high, count to *MaxInt*, and start at negative *MaxInt* before being read again. This is checked for and taken care of by the last *if-else* statement.

Procedure *RemoveBlanks*(VAR string1: string);

If the string parameter *string1* has any trailing blank or return characters, they will be removed by this function. White-space not at the end of *string1* will not be removed.

Procedure *Strip*(VAR string1: string);

This removes all non alpha-numeric characters from *string1*.

Function *CheckAnswer*(VAR answer: string; Possibles: NewRec): boolean;

A *NewRec*, declared in the file *ItemFileS*, is a record of one database element, or one element in the *InfoList*. Among other things, it contains an array called *NewRec.names*. Each element of this array is a possible correct answer for the particular item associated with *NewRec*. *CheckAnswer* capitalizes both the string-to-be-checked *answer*, and the possible names found in *Possibles*. All non-alphanumeric characters are also removed. If *answer* matches any one of the names found in *Possibles* or a concatenation of the two names in either order, then *CheckAnswer* returns *true*, otherwise *false*.
8. The File ItemFiler3

*ItemFiler3* is another game module (unit in UCSD Pascal) that is linked with the main game program *G/.IVAN*. *ItemFiler3* contains procedures and variable declarations that are vital to running of the game. In a nutshell, the primary role of *ItemFiler3* is to interface between the game program and the upper disk drive which contains games images and information vital to the game. It also has made variable declarations that are globally accessible to *G/.IVAN*. These variables most generally have to do with the dynamics of graphics manipulations in the game.

**IMPORTANT NOTE:** This module is highly DEVICE DEPENDENT since the many graphics procedures and variables defined here are designed specifically for use on the TERAK. If you plan on transferring *FLASH IVAN* to another machine, it is likely that most of the alterations in the *FLASH IVAN* game code will most likely occur in this module. Because *ITEMFILERS* is highly susceptible to future alterations, we have described variables and procedures in greater depth than we have elsewhere.

8.1. Important Constants

**MAXINDEX = 100:**

`MAXINDEX` indicates the upper bound of the array `INFO_LIST` described below.

**MAXNAMES = 3:**

`MAXNAMES` sets the array in the record defined below to a range of 3.

8.2. Important Global Variables

**INFO_LIST:** This is an array of records, each of which has a one to one correspondence to an image in the game. Although explained briefly in the GAMEUN3 module, we go into greater detail here since this is where it has been originally declared. Each record is structured as follows:

```pascal
type NEWREC = packed record
    NAMES: packed array[1..MAXNAMES] of str15;
    BLOCK: integer;
    FULLSCREEN: boolean;
    TOPTHIRD: boolean;
    MIDTHIRD: boolean;
end;
```

30
Note MAXNAMES equals 3; Names[1] and Names[2] hold the game names (up to 15 characters) of a particular image. Names[3] holds the fotofile name on which the image is located. BLOCK is the block number which corresponds to the fotofile name; after an image directory has been created its fotofile block location on the upper disk is automatically stored in BLOCK. By accessing a fotofile be BLOCK number using UNITREAD a game image can be accessed 3 to 4 times faster than if it were accessed by name using the usual Pascal file I/O. This makes for a faster, more interesting game. The remaining fields in the record, FullScreen, TopThird, MidThird, and BotThird are set to TRUE or FALSE depending upon which part of a fotofile an image is located. These fields enable the game creator the option of putting up to 3 images on fotofile, thus saving disk space. Record indices (in INFO_LIST) 90-100 have been set aside for gaming system images such as the opening Eagle animation. Record indices 1-89 are reserved specifically for the actual game images (of Aircraft in the prototype game).

CROSSHAIRS : is of type packed array[0..59,0..59] of boolean. It is a graphics buffer which holds the targetor icon which is flashed to the screen just before a game image is flashed to the screen.

SMALLSC : is a packed array[0..28351] of boolean used as a graphics buffer which is roughly the size of one third the screen. This buffer is used in the instance of a game image stored on a specific third of a fotofile which must be flashed to the screen. SMALLSC is actually larger than a third of a screen of bits (80 X 320) because it needs to accommodate a UNITREAD call which uses a BLOCK type format in reading information from disk. Thus the size of SMALLSC is exactly 7 blocks long (28352 bits). It is stored in a one dimensional array for the sake of convenience and clear understanding. When an image is read into SMALLSC, it is read in as a linear string of bytes. In addition to this complication, the very beginning of a thirdscreen image won’t always begin at the beginning of the buffer SMALLSC, since UNITREAD which begins reading from a Block number cannot always start reading from an exact bit location where an image’s string of bytes begins on disk. In the case of a TopThird image, there is no problem in this case, since its Block number corresponds exactly to its starting bit location. However, in the instance of MidThird or BotThird images whose starting bit
locations do not exactly correspond to a BLOCK number on disk, they are UNITREAD from a block number before their starting position. Although they easily fit into the oversized SMALLSC buffer, they do not begin at the beginning of SMALLSC. By keeping SMALLSC one-dimensional, offsets to the beginning of an image in SMALLSC are made easy to calculate.

**SCREEN**: is a packed array[0..239,0..319] of boolean; SCREEN acts as a graphics buffer with each boolean element mapping to a particular pixel on the TERAK screen. If a game image is of type *FullScreen*, it is read directly into SCREEN. If not, the game image is first read into SMALLSC and then bitmapped and centered on SCREEN. Whatever SCREEN contains can be projected to the screen with the command UnitWrite(3,SCREEN,69). SCREEN can be removed from the screen using the command UnitWrite(3,SCREEN,7) or Page(OUTPUT).

**CLOCK_INT**: is a case variant record which is used in procedure PAUSE.

**HI_LIST**: is an array of ten records containing the names and scores of the ten top scoring players. This information is read in from the upperdisk (the images disk) into this array and compared to the score of the current player at the end of each game. If the current player's score is within this range of scores, a new HI_LIST is created with his name and score inserted in the appropriate spot and written back to disk. See procedure HISCORE.

### 8.3. Procedures in *ItemFiler9*

Procedure **Delay(N : integer)**;

*Delay* is a simple procedure used to create time delays. A FOR loop is simply executed *N* times. It is estimated that the number of seconds of delay is equal to *N / 100*. So for example *Delay(400)* will simulate a 4 second delay.

Procedure **FromDisk(Var II_list : ILIST; I_name : str15)**;

*FromDisk* reads the image directory (in the case of our game, "#5:NEWNAMES") from the upper disk into the array INFO_LIST.
Procedure \textit{Display}(N : integer);

\textit{Display} will display the $N$th image in the array \textit{INFO\_LIST} on the TERAK screen and leaves it there. It is up to calling program to remove it from the screen; we reasoned that this implementation gives the calling program more freedom as to how long the image is to be displayed. \textit{Display} is very much device dependent, i.e. it is designed to run specifically on the TERAK. This is also true for the entire ITEMFILER3 module. If you plan on transferring FLASH IVAN onto a machine other than the TERAK, \textit{Display} is the procedure that will more than likely need revamping. Because of this procedure's importance, we have outlined it in greater detail than we have other routines:

- will first clear the screen
- then load the screen buffer \textit{SCREEN} with on bits
- then bitmap CROSSHAIRS onto \textit{SCREEN}
- then turn on \textit{SCREEN}
- for a second
- then turn off screen
- then will read the FOTOFILE that the image is
  -- on from disk
- IF FULLSCREEN = TRUE reads directly to \textit{SCREEN}
  -ELSE reads to \textit{SMALLSC}
  -- and then offset and bitmapped to \textit{SCREEN}
  -- then the image is projected to the screen

Function \textit{Pause} : boolean;

\textit{Pause} is currently not used in the game and is therefore commented out. Its function is to wait at most 10 seconds for a user response. If a user responds within 10 seconds, control is immediately returned to the calling program and \textit{Pause} returns FALSE. If a user hasn't responded within 10 seconds, \textit{Pause} returns TRUE.

Note: uses the case variant record \textit{Clock\_Int} described above

Procedure \textit{HiScore};

First, reads in top ten scores from file "\#5:HISCORE.DA TA" (on upper disk) and stores them in array \textit{Hi\_List}. Next, Displays \textit{HiScore} graphic on the screen (\textit{Info\_List}/100). Next, inserts and sorts current score \textit{SCORE} with scores in \textit{Hi\_List}; then outputs \textit{Hi\_List} array to the screen, and finally writes the modified \textit{Hi\_List} back to disk.
PROGRAM MAINTENANCE

9. The Disks

The Flash Ivan Gaming System consists of three essential disks:

1. The Game Code Disk
   -- goes in bottom disk drive
   -- holds the game code
   -- holds the stats file

2. The Images Disk
   -- goes in the upper disk drive
   -- holds game specific information:
      Fotofiles,
      the image directory,
      instructions,
      and the HISCORE.DATA file

3. The Administration Disk
   -- goes in the bottom disk drive
   -- operates on either of the
      other two disks in the top drive
   -- used to make a new game
   -- and to access and format game stats

10. Organization

With so many different disks floating around, some on the test site and some being used to make game enhancements, we have realized the necessity for tight organization among us. As we have worked on the program, we have adopted three important conventions to better organize ourselves. Firstly, we have chosen the following naming system:

"TOMCAT"[n] corresponding to game code disks
"IVAN_UP"[n] corresponding to images disks
"ADM" corresponding to the administration disk

where n represents a number. Secondly, we keep an exacting written record of each disk: the version of the game on it, where it is, and other vital information. Thirdly, we have designated master disks holding the most recent game enhancements:

"BIGBIRD" — holds most recent game code
"FOTOS1" — holds the most recent image directory, "NEWNAMES"
   as well as Fotofiles 1-30
"FOTOS2" — holds the remainder of the Fotofiles, Instructions,
   Initial Hiscores file, etc.

We have made these conventions for our own organizational purposes; you may or may not want to follow them exactly depending on your own tastes.
11. Disk Handling

In the suggestions that follow, we separately discuss the preparations needed for each disk in the FLASH IVAN Gaming System before and after it goes to the gaming site.

11.1. The Game Code Disk -- Before

The game code disk should have a minimal number of files on it before collecting performance data. The two most important files are $SYSTEM.STARTUP$, containing the game code, and $GAMES.DATA$, storing game stats. In order to accommodate new stats written to disk after each game, the game code disk should be Krunchsed (see P-System details) with $GAMES.DATA$ as the last file on the disk. This will allow the statistics file to utilize the remaining disk space the most efficiently. Lastly, it should be checked for any bad blocks.

11.2. The Game Code Disk -- After

When a game code disk returns from collecting data at a testing site, our primary interest is to access the statistics file $GAMES.DATA$ and then format it into something readable. The following sequence of instructions make this tedious task less burdensome:

1. Put "ADM" Disk in lower disk drive
2. Put game code disk in upper disk drive
3. Check game code disk for bad blocks
4. Get listing of game code disk.
   -- How big is $GAMES.DATA$?
   -- Is it still the last file on disk?
5a. Be sure $NEWNAMES$ is on ADM disk
5b. Clear ADM disk of any unnecessary files
   -- most notably old $CONFIDENCE.TEXT$ and $LATENCY.TEXT$ files
6. Krunch ADM disk
7. Execute Makestats (be patient; it takes a while to complete)
8. Check to see if new $CONFIDENCE.TEXT$ and $LATENCY.TEXT$ files are on ADM disk
   -- then print them out
9. If you wish to save these files,
   then transfer them to the STATS disks
10. Erase them from the ADM disk
11. Run game code disk with Image disk in upper drive
   -- selecting the version option at the beginning,
   see if the version is up to date

11.3. The Images Disk -- Before and After

The Images disk should be checked for bad blocks, frequently. Since data is constantly read from this disk during game time, it absorbs a lot of wear and tear. If ever you Krunch the disk or make any changes to it whatsoever, it is
extremely important that you "convert" the disk afterwards. The "conversion" function can be called from the MAKEDIR program on the "ADM" disk and is described in detail in the Flash Ivan Utilities Documentation.
