DAMs, INSPECTION, DAM SAFETY,
Merrimack River Basin
Concord, New Hampshire
Merrimack River

The dam is a run of the river type dam. It is 633 ft. long with a maximum height of 35.9 ft. The visual inspection of the dam revealed that the dam is in generally fair condition. Noted were some minor cracking and spalling of concrete on the abutments and the poor condition of the gates and mechanical operators. It is intermediate in size with a significant hazard potential.
SEWALLS FALLS DAM

MERRIMACK RIVER BASIN
CONCORD, NEW HAMPSHIRE

PHASE I INSPECTION REPORT
NATIONAL DAM INSPECTION PROGRAM
LETTER OF TRANSMITTAL

FROM THE CORPS OF ENGINEERS TO THE STATE

TO BE SUPPLIED BY THE CORPS OF ENGINEERS
Sewalls Falls Dam is a "run of the river" type dam. Overall length of the dam is 633 feet with a maximum height of 35.9 feet. The 497 foot long spillway is a timber deck/crib type structure constructed on three levels. The dam was originally constructed in 1892. There are no details of any later modifications to the dam. Engineering data available consists of a set of plans dated September-December, 1942, showing an overall plan view of the site, plan and cross sections of the spillway and details of the appurtenant structures. No construction specifications or design calculations were available.

The visual inspection of the dam revealed that the dam is generally in fair condition. The inspection revealed the loss of some timber deck/cribbing from the first apron of the spillway. The extent of the loss of the timber deck/cribbing could not be determined due to the high water level. Also noted were minor cracking and spalling of concrete on the abutments and the poor condition of the gates and mechanical operators.

Based on the dam's intermediate size and significant hazard classification in accordance with Corps of Engineers guidelines, the test flood is one half the Probable Maximum Flood (PMF). The test flood outflow does not overtop the dam. The spillway will pass 100 percent of the routed test flood outflow.

It is recommended that the owner engage a qualified engineer to further investigate the condition of the timber deck/crib spillway at a time when no water is flowing over the spillway. Also, the owner should repair the minor cracks and spalling of the concrete on the abutments in addition to investigating means of making the gates on the power diversion canal operable.
The recommendations and remedial measures described in Section 7 should be addressed within one (1) year after receipt of this Phase I - Inspection Report by the owner.

Gordon H. Slaney, Jr., P.E.
Project Engineer

Howard, Needles, Tammen & Bergendoff
Boston, Massachusetts
This Phase I Inspection Report on Darr Dam has been reviewed by the undersigned Review Board members. In our opinion, the reported findings, conclusions, and recommendations are consistent with the Recommended Guidelines for Safety Inspection of Dams, and with good engineering judgment and practice, and is hereby submitted for approval.

CHARLES G. TIERNSCH, Chairman
Chief, Foundation and Materials Branch
Engineering Division

FRED J. RAYENS, Jr., Member
Chief, Design Branch
Engineering Division

SAUL COOPER, Member
Chief, Water Control Branch
Engineering Division

APPROVAL RECOMMENDED:

JOE B. FRYAR
Chief, Engineering Division

THIS SHEET TO BE FURNISHED BY THE CORPS OF ENGINEERS
This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation and analyses involving topographic mapping, subsurface investigations, testing and detailed computational evaluations are beyond the scope of a Phase I Investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through continued care and inspection can there by any chance that unsafe conditions be detected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test Flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as necessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aide in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

</table>
5.1 Evaluation of Features

a. General. The Sewalls Falls Dam is a timber crib with stone fill structure 497 feet long with cut granite block abutments to give an overall length of 633 feet. The power diversion channel located on the west bank and associated structures have not been used since the dam passed from ownership by Concord Electric Company (1967) and did not enter into the hydraulic analysis.

The impoundment of water created by the dam was originally used for power generation, however, since the abandonment of the power facilities there is no specific use for the impounded waters. Sewalls Falls Dam is classified as intermediate in size having a maximum storage of 3,800 acre-feet.

b. Design Data. No hydrologic or hydraulic design data were disclosed for Sewalls Falls Dam.

c. Experience Data. The 1936 flood produced an estimated discharge of 115,000 cfs at Sewalls Falls. Flood elevations were recorded giving a headwater on the dam of 257.6 feet and a tailwater of 248.2 feet. Since the 1936 Flood, the Merrimack basin has experienced the construction of a large number of flood control projects. A report entitled "Water Resource Investigation, Merrimack River Basin" COE, NED, August 1972, predicts the discharge expected from various floods for both natural and regulated conditions.

d. Visual Observations. There was no evidence of damage to any portion of the project from overtopping visible at the time of inspection. However, it was noted that much of the timber cribbing of the first apron was missing, with only three short sections visible across the dam. The extent of the "lost" cribbing could not be determined due to the high water level.

e. Test Flood Analysis. As no detailed design and operational information are available, hydrologic evaluation was performed using dam information gathered by field inspection, watershed size and an estimated test flood equal to ½ the Probable Maximum Flood (PMF). As there is a detailed hydrologic study of the Merrimack River Basin (Water Resources Investigation Merrimack River Basin, New England Division, Corps of Engineers, August 1972) discharge at Sewalls Falls Dam was estimated to equal the Standard Project Flood, modified by existing Corps of Engineers Reservoir systems.
SECTION 4
OPERATIONAL PROCEDURES

4.1 Procedure

At the present time there is no specific use for the waters impounded by Sewalls Falls Dam. The water level in the reservoir is left to maintain its own stage with only the spillway crest as a control. The headgates to the power diversion canal are not used.

4.2 Maintenance of Dam

The dam is visited about once every two weeks by personnel of the New Hampshire Water Resources Board. During the visits the area is checked and the grass cut as necessary.

4.3 Maintenance of Operating Facilities

There is no regular maintenance for the operating facilities. Most of the gates are inoperable at this time.

4.4 Description of Warning Systems

There are no warning systems in effect at this facility.

4.5 Evaluation

The current operation and maintenance procedures for this dam are inadequate to insure that all problems encountered can be remedied within a reasonable period of time. The owner should establish a written operation and maintenance procedure as well as establishing a warning system to follow in event of flood flow conditions or imminent dam failure.
The design drawings indicate that there is a core wall/cutoff wall from the headgate structure to the powerhouse structure between the canal and the Merrimack River. The cutoff wall near the powerhouse structure could be seen at the time of inspection, but the core wall could not be seen. The depths of the core wall and cutoff wall are not known.

The now abandoned generating station is located at the end of the diversion channel. Visual inspection revealed that all structures related to the generating station are generally in fair to poor condition. The poor condition, as can be seen on Photo Nos. 19,20 and 22, apply primarily to the 50 foot long waste spillway and service bridge.

Water was passing through the wasteway at the downstream end of the canal at the time of inspection. The discharge channel downstream of the wasteway is shown in photo 25. The silt and sand bottom of the discharge channel was very soft. A small spring could be seen in the discharge channel floor in one location near the wasteway.

d. Reservoir Area. As this is a "run of the river" type dam there is virtually no reservoir. The river banks upstream of the dam are heavily wooded with no structures in the immediate area.

e. Downstream Channel. The channel downstream of the dam is about 500 feet wide with a wooded shore line. Other than the powerhouse and outlet works there are no other structures in the immediate area. The downstream channel is the natural river bed. No significant obstructions existed in the channel at the time of inspection.

3.2 Evaluation

Visual inspection indicates that the dam is in fair condition.

The inspection revealed the following:

1. Water over the spillway section prevented a thorough inspection of that section of the dam.

2. Loss of some timber cribbing/deck on the first apron of the spillway.

3. Minor cracking and spalling of concrete at construction joints for the abutments.

4. Inoperable gates at the intake structure for the power diversion canal.

5. Concrete in poor condition for the 50 foot long waste weir and abutment at the powerhouse.
The left wall of the dam is shown in photo 12. From a distance, this wall and the heavy rip-rap downstream of the wall appeared to be in good condition.

The heavy rip-rap downstream of the right wall of the dam was examined and appeared to be in excellent condition, photo 13.

c. Appurtenant Structure. Visual inspection of the timber crib/stone fill spillway, abutments with training and cut-off walls, intake structure to the power diversion channel and the now abandoned generating station did not reveal any evidence of stability problems. Abutment fascias with cut granite masonry are in good condition. The concrete surface, with exception of the abutments and cut-off walls, is in fair to poor condition; cracks and heavy spalling were noted on most of these surfaces. (Photo Nos. 2, 11, 19, 20 and 22.)

The intake structure at the power diversion channel consists of a massive cut granite structure and five (5) brick arch conduits with wooden gates. The intake structure is located at the right abutment. The gates, as originally designed, were operated by an electromechanical control system. Visual inspection revealed that the gate house and electrical equipment have been completely destroyed; mechanical controls are in very poor condition. The brick arch conduits to the power diversion channel were not inspected as they were partially below water level. The roof structure of these conduits appeared to be in good condition as can be seen on Photo No. 5. The downstream end of the headgate structure is shown in Photo No. 5. The intake channel to the headgates is shown in Photo No. 6. The stone masonry forming the headgate structure appeared to be in excellent condition with the exception of minor amounts of mortar missing in several areas.

The power diversion channel consists of a 1280 feet long channel between the intake structure and the now abandoned generating station, see Photo Nos. 7 and 21.

The sidewalls of the canal appeared to be in horizontal and vertical alignment above the water line at the time of inspection. Design drawings show that the walls on both sides are 12 feet in height and composed of 3 inch sheet pilings. The type of piling is unknown. The left wall is tied back near its top by a 10 foot long iron rod which is embedded in a reinforced concrete anchor at its end. The design drawings indicate that in back of the right canal wall and near its top there is an earth filled timber cribbing structure which is about 4.5 feet in height. Apparently, the right canal wall is attached to the timber cribbing. The power diversion channel is in good condition.
SECTION 3
VISUAL INSPECTION

3.1 Findings

a. General. The field inspection of Sewalls Falls Dam was made on April 20, 1979. The inspection team consisted of personnel from Howard, Needles, Tammen & Bergendoff and Geotechnical Engineers, Inc. Inspection checklists, completed during the visual inspection, are included in Appendix A. At the time of the inspection the water level was approximately 2.0 feet above the spillway crest. Only portions of the dam above the water level could be inspected.

b. Dam. Visual inspection of the dam indicated that the visible portions of the dam were generally in good condition. However, the condition of the spillway which constitutes a major portion of the dam could not be fully determined due to the high water. There are indications that the spillway may be in fair to poor condition.

The dam is comprised of timber cribbing filled with hand packed stone filling. Water of the Merrimack River flows over the entire crest of the spillway; the crest is 497 feet in length. A headgate structure to the right of the dam controls flow of water into a canal which leads to the powerhouse structure.

The spillway section consists of a timber crib/deck and stone structure, shaped as shown on Section A-A, Figure 1, located in Appendix B. The spillway structure extends through the entire width of the Merrimack River. On the day of inspection the entire spillway structure was under water, with approximately 2 feet of water over the spillway crest (see Photo No. 4). The crest of the spillway structure was visible and appeared to be in good condition.

There were however indications, by observing flow of the tailwater, that portions of the timber crib/deck structure in the first apron, were damaged. However, it was not possible to determine the extent of the damage due to the water flowing over the spillway. It was reported by the owner that the lower portions of the spillway were in poor condition.

The elevation of water after passing the crest is higher at the right end of the dam as shown in photo 8. The reason for this difference is unknown.

The abutments, consisting of cut granite fascias and concrete cut-off walls, are generally in good condition, except for some cracks and concrete spalling at the construction joints, see Photo No. 2.
SECTION 2
ENGINEERING DATA

2.1 Design

No original design data were disclosed for Sewalls Falls Dam. Original construction of this dam was completed in 1892. Extensive repairs to the dam were made in 1933 and 1934, however, the exact nature of the repairs was not disclosed. Plans showing the dam and appurtenances were made available.

2.2 Construction

No construction records were available for use in evaluating the dam.

2.3 Operation

No engineering operational data were disclosed.

2.4 Evaluation

a. Availability. Engineering data available for Sewalls Falls Dam is limited to the plans mentioned above. These plans are on file at the New Hampshire Water Resources Board, Concord, New Hampshire.

b. Adequacy. The lack of in-depth engineering data did not allow for a definitive review. Therefore, the adequacy of this dam could not be assessed from the standpoint of reviewing design and construction data, but is based primarily on visual inspection, past performance history and sound engineering judgement.

c. Validity. The field investigation indicated that external features of Sewalls Falls Dam substantially agree with those shown on the available plans.
(4) Top Width - 12.0 foot wide crest to spillway which is main portion of dam
(5) Side Slopes - US = 4:1; DS = stepped.
(6) Zoning - unknown.
(7) Impervious core - N/A.
(8) Cutoff - unknown.
(9) Grout Curtain - unknown.
(10) Other - unknown.

h. Diversion and Regulating Channel
    See Section j below.

i. Spillway
(1) Type - timber crib 12' wide at top.
(2) Length of Weir - 497 feet.
(3) Crest Elevation - 240.9.
(4) Gates - none.
(5) U/S Channel - Natural River Channel.
(6) Downstream Channel. The channel downstream of the dam is about 500 feet wide with a wooded shore line. Other than the power house and outlet works there are no other structures in the immediate area.

j. Regulating Outlets. The power canal level is regulated at the upstream end by five 107 square foot openings controlled separately by mechanically operated gates. At the downstream end of the canal, flow can be routed through the power building (inoperable at present) over a 50 long waste weir with its crest at 242.86 feet, through a 10 foot by 8'-6" wasteway gate invert 235.86 or a 6'-6" by 4'-8" bleeder gate invert 225.86. With the water surface on the spillway crest elevation the capacity of the outlet works is about 880 cfs.
(5) Full flood control pool - N/A.

(6) Spillway crest (permanent spillway) - 240.9.

(7) Design surcharge - unknown.

(8) Top Dam - 259.1

(9) Test Flood Surcharge - 253.8

d. Reservoir (miles)

(1) Length of Maximum Pool - N/A.

(2) Length of Recreational Pool - N/A.

(3) Length of Flood Control Pool - N/A.

e. Storage (Acre-Feet)

(1) Recreation Pool - N/A.

(2) Flood Control Pool - N/A.

(3) Spillway Crest Pool - 3,070.

(4) Top of Dam - Unknown

f. Reservoir Surface (Acres)

(1) Recreation Pool - N/A.

(2) Flood Control Pool - N/A.

(3) Spillway Crest - 350.

(4) Test Flood Pool - 350.

(5) Top Dam - 350.

g. Dam

(1) Type - timber crib.

(2) Length - 633 feet, overall.

(3) Height - 35.9 feet (maximum).
g. Purpose of Dam. Originally, this dam was used for power generation by the Concord Electric Company. At the present time there is no specific use for the water impounded by the dam.

1.3 Pertinent Data

a. Drainage Area. The drainage area tributary to Sewalls Falls Dam consists of 2,233 square miles of terrain varying from flat to mountainous. Major tributaries to the Merrimack River Above this point include the Contoocook River, Winnipesaukee River and the Pemigewasset River. The basin is regulated by many large reservoirs which include: Franklin Falls, Hopkinton-Everett, Blackwater Reservoir, Edward MacDowell Reservoir, and Newfound Lake. These Corps of Engineers reservoirs provide a large potential for flood regulation.

As the Sewalls Falls Dam is a "run of the river" type dam, the reservoir impounded by it is small.

b. Discharge at Dam Site

(1) Outlet works for the dam consist of a 1,280 foot long power canal regulated at its head by five 10 foot wide gates at invert elevation 229.96. Capacity of the outlet works including the gates at the power house is approximately 880 cfs with the water surface at the spillway crest. At the powerhouse, there is a 10 by 8.5 foot waste gate at invert 235.86 and a 6.5 by 4.7 foot bleeder gate at invert 225.86.

(2) The maximum discharge at the site is estimated to be 115,000 cfs based on a recorded discharge of 122,000 cfs at Garvins Falls 11 miles downstream in March of 1936. A headwater of 257.6 feet and a tailwater of 248.2 feet was recorded at Sewalls Falls in March of 1936. It is predicted that a repeat of the 1936 flood, with flood control regulation, would produce a discharge of 57,000 cfs at Garvins Falls.

(3) The spillway capacity with a water surface at the top of dam (elevation 259.1) is approximately 145,300 cfs.

(4) The spillway capacity with the water surface at the test flood elevation of 253.8 feet is approximately 86,550 cfs.

(5) The total project discharge at the test flood elevation of 253.8 feet is approximately 86,550 cfs.

c. Elevation (feet above MSL)

(1) Streambed at centerline of dam - 223.2
(2) Maximum tailwater - 248.2 (1936 flood).
(3) Upstream portal invert diversion channel - 229.96.
(4) Recreational pool - N/A
b. Description of Dam and Appurtenances. Sewall's Falls Dam is a "run of the river" type dam. Overall length of the dam, according to the plans is 633 feet. The 497 foot long timber crib and stone fill spillway was constructed on three levels, crest, first apron and second apron. According to the plans, the timber cribbing has a vertical upstream face with stone and gravel fill placed to within several feet of the crest on a 4 horizontal to 1 vertical slope. Abutments are constructed of cut granite masonry. The west abutment is extended 130 feet downstream with a cut granite block rip-rap, stepped on approximately a 1:1 slope. The east abutment is continued by approximately 40 feet of cut granite block rip-rap.

Head gates to a power diversion channel are located west of the end of the west abutment. There are five 10 foot wide gates which lead to a 1,280 foot long diversion channel. The now abandoned generating station is located at the end of the diversion channel. In addition to the 7 penstock gates indicated on the plans, there is a 50 foot waste weir and 2 control gates.

Figures 1 and 2 located in Appendix B, show the plan of the dam and appurtenant structures. Photographs of each structure are shown in appendix C.

c. Size Classification. Intermediate (Hydraulic height-35.9 feet, storage - 3,800 acre-feet) classification based on storage being between 1,000 and 50,000 acre-feet as given in Recommended Guidelines for Safety Inspection of Dams.

d. Hazard Classification. The hazard to life and property poised by this dam is classified as significant. A major breach of dam (when the upstream pool elevation is at the top of dam) would result in a maximum rise of 1.6 feet in downstream water level through Concord. This additional rise in water surface will further inundate an already flooded, highly developed area and will probably expand the flood hazard area. The downstream stage, prior to breach of dam, would also present a great hazard to life and property.

e. Ownership. This dam is now owned by the New Hampshire Water Resources Board, 37 Pleasant Street, Concord, New Hampshire. Prior to 1967 the dam was owned by Concord Electric Company.

f. Operator. This dam is maintained and operated by the New Hampshire Water Resources Board. Chairman of the Water Resources Board is Mr. George M. McGee, Sr.; Mr. Vernon Knowlton is Chief Engineer, Telephone No. 603/271-110.
NATIONAL DAM INSPECTION PROGRAM
PHASE I INSPECTION REPORT
SEWALLS FALLS DAM

SECTION 1
PROJECT INFORMATION

1.1 General

a. Authority. Public Law 92-367, August 8, 1972, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a National Program of Dam Inspection throughout the United States. The New England Division of the Corps of Engineers has been assigned the responsibility of supervising the inspection of dams within the New England Region. Howard, Needles, Tammen & Bergendoff has been retained by the New England Division to inspect and report on selected dams in the State of New Hampshire. Authorization and notice to proceed were issued to Howard, Needles, Tammen & Bergendoff under a letter of October 23, 1978 from John P. Chandler, Colonel, Corps of Engineers. Contract No. DACW33-78-C-0356 has been assigned by the Corps of Engineers for this work.

b. Purpose

(1) To perform technical inspection and evaluation of non-Federal dams to identify conditions which threaten the public safety and thus permit correction in a timely manner by non-Federal interests.

(2) To encourage and prepare the states to initiate quickly effective dam safety programs for non-Federal dams.

(3) To update, verify and complete the National Inventory of Dams.

1.2 Description of Project

a. Location. Sewalls Falls Dam is located along the Merrimack River approximately 2.5 miles downstream of its confluence with the Contoocook River in Concord, New Hampshire. The dam is shown on U.S.G.S. Quadrangle Penacook, New Hampshire with approximate coordinates N43° 15' 40", W71° 33' 10", Merrimack County, New Hampshire. The dam location is shown on the preceding page.

APPENDIX D - HYDROLOGIC AND HYDRAULIC COMPUTATIONS
APPENDIX E - INFORMATION AS CONTAINED IN THE NATIONAL INVENTORY OF DAMS
Based on a drainage area of 2,233 square miles, the test flood inflow was estimated to be 86,900 cfs. Following the guidance of Estimating Effect of Surcharge Storage on Probable Maximum Discharge results in a test flood outflow of 86,550 cfs. As the maximum capacity of the spillway is 145,300 cfs, the spillway can pass 100 percent of the routed test flood outflow.

f. Dam Failure Analysis. The impact of failure of the dam at maximum pool (top of dam) was assessed using the "Rule of Thumb" Guidance for Estimating Downstream Dam Failure Hydrographs issued by the Corps of Engineers. The analysis covered the reach extending from the dam to a point 10.4 miles downstream in Concord, New Hampshire.

Failure of Sewalls Falls Dam with the pool at the top of dam results in an increase of 1.6 feet in the downstream stage or from 30 feet to 31.6 feet. The 1.6 foot increase will be lowered to a 0.9 foot increase 3 miles downstream and 0.6 feet 10.4 miles downstream due to channel storage. It is considered that a stage of 30 feet, which represents the maximum spillway flow, would be a major flood. An additional rise of 1.6 feet from the breach of dam would most likely produce additional property damage in the highly developed commercial and residential areas on the flood plain in Concord. The marginal difference in hazard to life could not be considered high.
SECTION 6
STRUCTURAL STABILITY

6.1 Evaluation of Structural Stability

a. Visual Observation. The visual observations did not disclose any immediate stability problems, however, a thorough visual inspection of the spillway could not be made because of water flow over the crest.

b. Design and Construction Data. Design drawings of Sewalls Falls Dam dated September - December, 1942 are available.

Information on these drawings include:
1. Plan view of dam and outlet works.
2. Plan view of core wall and cutoff wall between the headgate structure and powerhouse structure.
3. Plan views and cross sections through the dam. The dam consists of timber cribbings fitted with "hand packed" stone. The dam is founded on "hardpan". A cross sectional drawing of the dam indicates 3" and 4" sheet piling at four locations beneath the dam and parallel to the dam's longitudinal axis. No depths are given for the sheet piling.
4. A 4 horizontal to 1 vertical slope of stone and gravel rests against the upstream face of the timber cribbing.
5. Design details of the left and right walls of the canal are given. The tieback systems for the walls are given.

c. Operating Records. No operating records were made available.

d. Post-Construction Changes. The original dam was built in 1892. Documentation of the dam history since 1892 is too vague to determine if significant changes were made to the dam after construction.

e. Seismic Stability. The dam is located in Seismic Zone 2, and in accordance with recommended Phase I guidelines does not warrant seismic analysis.
SECTION 7
ASSESSMENT, RECOMMENDATION AND REMEDIAL MEASURES

7.1 Dam Assessment

a. Condition. The visual inspection of Sewalls Falls Dam indicates that the dam is in fair condition in so far as the portions seen during the inspection are concerned. A complete assessment of the spillway section could not be made due to high water. The inspection revealed the following:

(1) Loss of some timber deck/cribbing on the first apron of the spillway.

(2) Minor cracking and spalling of concrete at construction joints for the abutments.

(3) Inoperable gates at the intake structure for the power diversion canal.

(4) Concrete in poor condition for the 50 foot long waste weir and abutment at the power house.

The hydraulic analysis reveals that the spillway can pass the routed test flood without overtopping of the dam.

b. Adequacy of Information. The lack of in-depth engineering data did not allow for a definitive review. Therefore, the adequacy of this dam could not be assessed from the standpoint of reviewing design and construction data but is based primarily on visual inspection, past performance history and sound engineering judgment.

c. Urgency. This dam is in generally fair condition. The recommendations described in Section 7.2 and the remedial measures described in Section 7.3 should be accomplished within 1 year, unless otherwise noted, after receipt of this Phase I Inspection Report by the owner.

d. Necessity of Additional Investigation. Due to the high water over the spillway section of the dam the extent of the loss of timber deck/cribbing could not be fully determined. Some means of reducing or diverting the flow over the spillway should be devised in order to allow for a complete examination.

7 - 1
7.2 **Recommendations**

It is recommended that the owner engage a qualified engineer to further investigate the condition of the timber deck/cribbing spillway at a time when no water is flowing over the spillway.

7.3 **Remedial Measures**

(a) Minor cracking and spalling of concrete at construction joints for the abutments should be repaired.

(b) A means for making the control gates operable on the power diversion canal should be investigated.

(c) A written operational procedure and warning system to follow in the event of flood flow conditions or imminent dam failure should be developed.

(d) Initiate a program of annual periodic technical inspection.

7.4 **Alternatives**

There are no practical alternatives to the recommendations of Sections 7.2 and 7.3.

APPENDIX D

HYDROLOGIC AND HYDRAULIC COMPUTATIONS
Sewalls Falls Dam located in Concord N.H. across the Merrimack River

Classification
Size: Intermediate
Hazard: Significant

Basic Data
D.A.: 2233 c.f.s. checked by HNTB
Upstream basin: flat, s = 0.00227

Reservoir: Run of River Type
Normal: Storage: 3070 acre-ft
@ elev. 240.86
Max: Storage: Unknown

Dam: Timber crib & earth
Length: 600' ±
Max height: 35.9 ft

Spillway: Timber Crib
Length: 497'
Crest elev. 240.86

Outlet works:
Waste weir control 50' long
Crest at 242.86
Sewalls Falls

Plan (no scale)

Spillway Crest elev 240.86

Longitudinal Section

Flow

Spillway X-see

Gate

X-see thru outlet works
1 Peak Inflow: Cal. Test Flood Inflow

Classification: Size - Intermediate
Hazard: Significant - Flood levels as calculated from the downstream damage evaluation would raise the maximum spillway discharge stage of 300 ft. by 1.6 feet.

In 1936 at Garvins Falls DA 2427 sqa.
Discharge = 122,000 cfs

Hyrologic Evaluation Guideline Recommends
\( \frac{1}{2} \text{PMF to PMF} \)

Use \( \frac{1}{2} \text{PMF} \) as size of reservoir on low end of range.
The 2233 sqa. drainage area tributary to the Sewalls Falls Dam is outside the PMF guide curve envelope. Extrapolation of the curve to 2233 sqa. will yield unreliable results.

From: "Water Resources Investigation Merrimack River Basin" DOE, August 1972

<table>

<td>86,900 cfs</td>
</tr>
</tbody>
</table>

without upstream flood control structures
In flat coastal areas, the PMF is based on twice the standard project flood (ref. "Preliminary Guidance for Estimating Maximum Probable Discharges").

Therefore use the standard project flood discharge modified by existing flood control systems.

**Test Flood Inflow = 86,900 cfs**
2 Calculation of Surcharge by SDF

\[ \text{INFLOW} = 86,900 \text{ cfs} \]

Consider:
1. Flow over spillway only
2. Gates for power canal closed

**Spillway weir hydraulics**

\[ Q = C \frac{L^2 H}{2} \text{ crest} \]

where \( C = 3.75 \) Coefficient includes approach velocity

\[ L = 497 \text{ ft.} \]

\[ Q = 3.75 \times (497)^2 \times H^2 = 1864 H^3 \text{ cfs} \]

At Sewalls Falls 1936 flood est. discharge 115,000 cfs

Recorded HW elev 257.6

" TW elev 248.2

Tailwater will not significantly affect discharge over spillway at \( Q = 100,000 \text{ cfs} \) or less.

</tbody>
</table>
Effect of Surcharge Storage on Test Flood

PMFR = 9.5" as SDF = ½ PMF
Reservoir surface area = 350 acres

\[ Q_{P1} = 86,900 \text{ cfs} \]

Surcharge \( s_1 = 253.8 - 240.9 = 12.9 \text{ ft} \)

\[ h_1 = \frac{12.9 \text{ ft} \times 12 \text{ in/ft} \times 350 \text{ acres}}{2233 \text{ sqmi} \times 640 \text{ acres}} = 0.038 \text{ in} \]

\[ z = Q_{P1}(1 - \frac{s_1}{9.5}) = 86,900(1 - \frac{12.9}{9.5}) = 86,550 \text{ cfs} \]

Surcharge \( z = 12.9 \text{ ft} \)

\[ z = \frac{12.9 \times 12 \times 350}{2233 \times 640} = 0.038 \text{ in} \]

\[ h_{ave} = \frac{S_{ori} + S_{ori}}{2} = 0.038 \text{ in} \]

Small storage available, surcharge values will not
influence appreciably from values calculated

\[ Q_{P3} = 3 \times 86,550 = 86,600 \text{ cfs} \]

Stage = 12.9 ft, elev. 253.8
Conclusions

Reservoir storage will reduce the test flow at the outlet from 86,900 cfs to 86,550 cfs or by 0.47%.

Pillarway and storage capacity can safely absorb 100% of the test flood.

The test discharge of 86,550 cfs the dam will not be overtopped.
Estimate of Downstream Damage

Reservoir Capacity

Normal: 3070 acre-ft @ 240.9 ft
Max: unknown
Effective Max: 1540 acre-ft @ 259.1 ft see fig

Peak Failure Outflow

\[ P_i = \frac{8}{27} \sqrt[3]{w} \times \frac{y^2}{y} \]

\[ w_0 = 40\% \text{ of dam width} = 40\% \times \text{fig} \]

\[ y_0 = \text{height from river bed to max. pool} = 35.9 \text{ ft} \]

\[ P_i = \frac{8}{27} \sqrt[3]{497 \times (35.9)^2} = 71,800 \text{ cfs} \]

Stage-Discharge Rating Curve

Channel: \( n = 0.03 \)

Overbanks: \( n = 0.07 \)

Reach Characteristics

\( S = 0.0033\% \text{ (1936 flood profile)} \)

\( n = 0.03 \text{ channel} \)

\( 0.07 \text{ overbank} \)

St. Discharge

\( Q = 11,600 \text{ cfs} \)

70,000

103,400

145,100

190,900
As this is a run of the river dam the full outflow at breach of dam will also include some of the spillway outflow.

Outflow including spillway discharge

\[ Q_T = 60\% \text{ of full spillway} + \text{Breach outflow} \]

\[ 0.6 \times 145,300 + 71,800 = 159,000 \text{ cfs} \]

Downstream stage @ 159,000 cfs = 31.6 ft

\[ @ 145,300 \text{ cfs} = 30.8 \text{ ft} \]

**Step 4**  
**Downstream Hydrograph**  
\[ S = 1540 \text{ acre-ft} \]

\[ Q_p = 159,000 \text{ cfs} \]
\[ Q_s = 145,300 \]
\[ \Delta Q = 13,700 \text{ cfs} \]

\[ V_1 = \frac{16,000 \times (1900)}{43560} = 698 \text{ acre-ft} < 720 \text{ acre-ft} \text{ UK} \]

\[ \Delta Q_{\text{trial}} = 13,700 \left(1 - \frac{698}{1540}\right) = 7500 \text{ cfs} \]

\[ Q_p = 152,800 \text{ cfs} \]
\[ \Delta Q_p_1 = 13,700 \left(1 - \frac{437}{1540}\right) = 9,400 \text{ cfs} \]
\[ Q_{p_2} = 15,4,700 \text{ cfs} \quad \text{Stage} \ 30.9 \text{ ft} \]

\[ V_2 = \frac{16000 \times 750}{43560} = 275 \text{ acre-ft} \]
\[ V_{ave} = 487 \text{ acre-ft} \]

\[ \Delta Q = 9,400 \text{ cfs} \quad \Delta A = 1110 \text{ ft}^2 \]

\[ V_1 = \frac{18,000 \times 1110}{43560} = 459 \text{ acre-ft} < \frac{1540}{2} = 0 \text{ k} \]

\[ \Delta Q_{p_2} = 9,400 \left(1 - \frac{459}{1540}\right) = 6600 \text{ cfs} \]
\[ Q_{p_2} = 15,1900 \text{ cfs} \quad \text{Stage} \ 30.5 \text{ ft} \]
\[ \Delta A_{ave} = 635 \text{ ft}^2 \]

\[ V_2 = \frac{18,000 \times 635}{43560} = 262 \text{ acre-ft} \]
\[ V_{ave} = 361 \text{ acre-ft} \]

\[ \Delta Q_{p_2} = 9,400 \left(1 - \frac{361}{1540}\right) = 7200 \text{ cfs} \]
\[ Q_{p_2} = 15,2,500 \text{ cfs} \quad \text{Stage} \ 30.6 \text{ ft} \]
Note: 2/3 Rule for downstream breach wave
not applicable due to high river stage
prior to breach of dam

Downstream Stage prior to breach 320
Reservoir Capacity
Storage for D.D. Cals

Length: 22,700 feet
Top of dam 259.11

Slope: 5%
Depth in channel = d.s. depth
w/o dam

Storage prism
5.9'
Spillway w.s.
94'
Spillway

ds. depth

inv. 223.2

Spillway Flow with water surface at top of dam

145,300 cfs Stage 30.0 ft d.s. of dam = ws. of
253.2
Top of dam = 259.1
Downstream w.s. 253.2
height of storage prism = 5.9 ft

Length of pool 5.9 x 0.0026 Vs = 22,700 ft

Assume ave flood plain width of 1000 ft in upstream areas

Storage volume = \( \frac{5.9 \times 22,700}{2} \times 1000 \)

= 1537 acre-ft
Outlet works - Discharge Capacity at top of spillway

5-107 sq ft gates  imm. 229.9 ft
10' x 8.5' waste gate imm. 235.86
6.5' x 4.67' bleed gate imm. 225.86
1280' diversion canal  10' x 100' x-dec approximate

Bleeder gate
\[ Q = CA \sqrt{H} \]
\[ A = 30.36 \text{ ft}^2 \]
\[ C = 0.7 \]
\[ H = 10.17 \text{ ft} \]
\[ Q = 0.7(30.36) \sqrt{10.17} = 544 \text{ cfs} \]

Waste gate  10' wide  \( H = 4.84 \text{ ft} \)

\[ Q = \left( \frac{4.84}{10} \right)^{1.5} \sqrt{H} = \frac{4.84}{10} \sqrt{4.84} = 329 \text{ cfs} \]

Total three gates at elbow 2407 = 873 cfs

Trussed three canal
\[ A = 1000 \text{ sq ft} \]
\[ R = 8.33 \]

\[ H_g = S_5 \times L = \left( \frac{Q \cdot R}{A \cdot 1.49} \right) \times 1280 = \left( \frac{873 \times 0.3}{8.33 \times 1000 \times 1.49} \right) \times 1280 \]

\[ H_g = 1.83 \times 10^{-5} \times 1280 = 0.02 \text{ ft} \]
Water surface at head of small gate:

\[ h = \frac{Q}{C H} = \frac{873}{60 \times 5} = 0.11 \text{ ft} \]

Height of gate:

\[ Q = C H \sqrt{2g h} \]

\[ 240.7 \pm 0.02 \]

Head upstream of gate:

\[ 240.72 \pm 0.11 \]

Capacity of outlet works about 880 cfs.
Possible Flood Damage Area Due to Dam Failure
