A NOTE ON CONVERGENCE OF FUNCTIONS OF RANDOM ELEMENTS

Convergence of \( g(\xi_n) \) to \( g(\xi) \) is considered when \( \xi_n \rightarrow \xi \) in distribution or in probability, without the usual restriction that \( g \) be continuous a.s. under the distribution of \( \xi \). It is shown that the convergence \( g(\xi_n) \rightarrow g(\xi) \) holds for arbitrary Borel-measurable \( g \), if in addition to the assumed convergence \( x_n \rightarrow x \), the corresponding measures \( \{P_n\} \) of \( \{\xi_n\} \) are "contiguous" to the measure \( P \) of \( x \) in a certain very weak sense. Some statistical applications are indicated.

AMS 1980 subject classifications: Primary 60B10, Secondary 60F05

Key words and phrases: convergence in distribution, convergence in probability, convergence of transformed random elements, contiguity
1. **Introduction and preliminaries.** Many statistical applications of probability theory involve a question of convergence of \( g(\xi_n) \) to \( g(\xi) \), \( n \to \infty \), where \( g \) is a given function applied to a sequence of r.v.'s \( \xi_n \) convergent in some sense to \( \xi \). Typically, the discontinuity set of the function \( g \) is required to have measure 0 with respect to the distribution of \( \xi \). (See, e.g., Billingsley (1968), §5, and Serfling (1980), §1.7.) However, in some cases it is of interest to relax this assumption on \( g \). Here it is shown that \( g \) may be an arbitrary Borel-measurable function, if in addition to the assumed convergence \( \xi_n \to \xi \) the corresponding measures \( \{P_n\} \) of \( \{\xi_n\} \) are contiguous to the measure \( P \) of \( \xi \) in a certain very weak sense.

We will consider \( \{\xi_n\} \) and \( \xi \) to be random elements of a metric space \((S, \rho)\), and we will assume that \( S \) is separable (in order that \( \rho(\xi_n, \xi) \) be a well-defined random variable and that \( P \) be regular) and locally compact (in order that Luzin's theorem be applicable). We shall treat convergence of \( \xi_n \) to \( \xi \) in distribution, \( \xi_n \overset{d}{\to} \xi \) (by which we mean that the distributions \( P_n \) converge weakly to \( P \), \( P_n \to P \)), and in probability, \( \xi_n \overset{P}{\to} \xi \) (by which we mean that \( \{\xi_n\} \) and \( \xi \) are defined on a common probability space \((\Omega, \mathcal{A}, \mathbb{P})\) and that \( \mathbb{P}\{\rho(\xi_n, \xi) > \varepsilon\} \to 0, n \to \infty \), each \( \varepsilon > 0 \)). As is well-known (Billingsley (1968), p. 26), \( \xi_n \overset{P}{\to} \xi \) implies \( \xi_n \overset{d}{\to} \xi \).

Let \((X, \mathcal{A})\) be an arbitrary measurable space. Given probability measures \( \{P_n\} \) and \( P \) on \( \mathcal{A} \) and a particular sequence \( \{A_m\} \) in \( \mathcal{A} \) such that \( P(A_m) \to 0, m \to \infty \), we shall say that the sequence \( \{P_n\} \) is weakly contiguous to \( P \) at the sequence \( \{A_m\} \) if
This is a weak variant of the classical notion of contiguity due to LeCam (1960) and used by Hájek and Šidák (1967), which requires that $P_n(A_n) \to 0$ for every sequence $\{A_n\}$ such that $P(A_n) \to 0$.

REMARK 1.1. (i) Note that the above notion of weak contiguity is much weaker than, and implied by, equicontinuity of $\{P_n\}$ at $\emptyset$ (Kingman and Taylor (1966, p. 177), which requires that

\[
\limsup_{n \to \infty} P_n(A_m) = 0
\]

for every sequence $\{A_m\}$ decreasing to $\emptyset$. The limit in (1.1) is less than or equal to that in (1.2), we do not require that $A_n \to \emptyset$, and we permit restriction to a single sequence $\{A_n\}$.

(ii) Also, the above notion of weak contiguity is much weaker than, and implied by, uniform absolute continuity of $\{P_n\}$ with respect to $P$, which requires that for every $\epsilon > 0$ there exists $\delta > 0$ such that $P(A) < \delta$ implies $\sup_{n} P_n(A) < \epsilon$.

(iii) The above weak notion of contiguity is relevant to the problem of convergence of $g(\xi_n)$ to $g(\xi)$, because our treatment will require merely that (1.1) hold for a single rather special sequence $\{B_n\}$ defined in terms of the given function $g$ and the limit measure $P$ through an application of Luzin's theorem, as will be seen below.

(iv) A further motivation for restricting to contiguity at a single sequence arises from certain statistical applications, to be
discussed in detail in Section 2, in which the measures \( \{P_n\} \) are in fact empirical measures based on a collection of observations each having distribution \( P \). In such a situation, it is not true that the sequence \( \{P_n\} \) is with probability 1 contiguous to \( P \), or equicontinuous at \( \emptyset \), or uniformly absolutely continuous with respect to \( P \). However, it is easily seen that if the empirical measures \( \{P_n\} \) (and here we are allowing consideration of empirical measures not necessarily the classical versions) satisfy a set-wise strong law (i.e., for each \( A \in \mathcal{A} \), with probability 1 \( \{P_n\} \) satisfies \( P_n(A) = P(A), n \rightarrow \infty \)), then for any given sequence \( \{A_n\} \) with \( P(A_n) \rightarrow 0 \), the sequence \( \{P_n\} \) satisfies (1.1) with probability 1. This "set-wise strong law property" is usually easily established for reasonable notions of empirical measure.

Now take \((X,A) = (S,S)\), where \((S,\rho)\) is a separable and locally compact metric space and \( S \) is the Borel \( \sigma \)-algebra generated by the open sets. We specify as follows the sequences \( \{A_m\} \) in \( S \) which will arise for consideration in our development. Let \( g: S \rightarrow \mathbb{R} \) be \( S \)-measurable. By separability of \( S \) the measure \( P \) on \( S \) is regular, so that by local compactness of \( S \) we may apply Luzin's theorem (Halmos (1950), p. 242; Cohn (1980), p. 227), which implies the existence of continuous functions \( g_m: S \rightarrow \mathbb{R} \) and sets \( B_m \) such that \( P(B_m) + 0, m \rightarrow \infty \), with \( S - B_m \) compact and \( g = g_m \) on \( S - B_m \) \((m = 1,2,\ldots)\). We shall call \( \{g_m,B_m\} \) a Luzin sequence for \( g \) with respect to \( P \).

Our main results and applications will be presented in Section 2. One application will concern Lemma 2.1 of van Zwet (1980), which in part provided the inspiration for this study. A broad class of
applications is typified by the question of almost sure convergence of statistics of the form \( T_n = \int g \circ F_n^{-1}(t) J_n(t) dt \), where \( g(\cdot) \) and \( J_n(\cdot), n \geq 1 \), are specified functions, \( F_n(\cdot) \) is the usual empirical df based on an i.i.d. sample \( X_1, \ldots, X_n \) from a df \( F \), and \( F_n^{-1}(t) \) denotes the sample \( t \)-quantile, \( F_n^{-1}(t) = \inf\{x: F_n(x) \geq t\} \).

2. A convergence theorem and some applications. Without ado, we give

**THEOREM 2.1.** Let \((S, \rho)\) be a separable and locally compact metric space and \( S \) the corresponding Borel \( \sigma \)-algebra, and let \( \{P_n\} \) and \( P \) be probability measures on \( S \). Let \( g: S \rightarrow \mathbb{R} \) be \( S \)-measurable and suppose that \( \{P_n\} \) is weakly contiguous to \( P \) at \( \{B_m\} \), where \( \{g_m, B_m\} \) is a Luzin sequence for \( g \) with respect to \( P \).

(i) Suppose that \( P_n \Rightarrow P \). Then

\[
P_n g^{-1} \rightarrow P g^{-1}. \tag{2.1}
\]

(ii) Let \( \{\xi_n\} \) and \( \xi \) be measurable mappings from a probability space \((\Omega, \mathcal{A}, \mathbb{P})\) into \( S \) with corresponding measures \( \{P_n\} \) and \( P \), and suppose that \( \xi_n \Rightarrow \xi \). Then

\[
g(\xi_n) \xrightarrow{P} g(\xi). \tag{2.2}
\]

**PROOF.** We first prove (ii), which then will be utilized in the proof of (i). Let \( \epsilon > 0 \) be given, choose an integer \( m \geq 1 \), and write

\[
\mathbb{P}\{|g(\xi_n) - g(\xi)| > \epsilon\} \leq \alpha_n + \beta_n + \gamma_m.
\]
where \( a_{n,m} = \mathbb{P}(\xi_n \notin B_m, \xi \notin B_m' | g_m(\xi_n) - g_m(\xi) > \epsilon), b_{n,m} = \)
\[
\mathbb{P}(\xi_n \in B_m) = \mathbb{P}_{n,m}(B_m), \text{ and } \gamma_m = \mathbb{P}(\xi \in B_m) = \mathbb{P}(B_m). \]

(This is possible by the definitions and discussion of Section 1.) By the uniform continuity of \( g_m \) on \( B_m, \exists \delta_{m, \epsilon} \) such that \( \rho(x, y) < \delta_{m, \epsilon} \) implies
\[
|g_m(x) - g_m(y)| < \epsilon \text{ for } x, y \in S - B_m. \]
Hence \( a_{n,m} \leq \mathbb{P}(\rho(\xi_n, \xi) > \delta_{m, \epsilon}), \) and by \( \xi_n \overset{P}{\rightarrow} \xi \) we thus have \( a_{n,m} \to 0 \) as \( n \to \infty \). Therefore,
\[
\lim_{n \to \infty} \sup \mathbb{P}(\{|g(\xi_n) - g(\xi)| > \epsilon\}) \leq \lim_{n \to \infty} \sup b_{n,m} + \gamma_m. \tag{2.3}
\]

We now let \( m \to \infty \), applying (1.1) and the fact that \( \gamma_m \to 0 \), and obtain (2.2). Thus (ii) is proved.

To prove (i), we apply a representation of Skorokhod (1956) as extended by Dudley (1968), to introduce a probability space \((\Omega_0, \mathcal{B}_0, \mu_0)\)
and \( \mathcal{B}_0 \) - \( S \)-measurable \( S \)-valued functions \( \{\eta_n\} \) and \( \eta \) defined on \( \Omega_0 \) such that the distribution of \( \eta_n \) is \( \mathbb{P}_n (n = 1, 2, \ldots) \) and that of \( \eta \) is \( \mathbb{P} \), and \( \eta_n \to \eta, n \to \infty, \text{ a.s. } [\mu_0] \). Here \( \Omega_0 = \Omega \times \Omega_*, \) where \( \Omega_* = \prod_{n=1}^{\infty} \Omega_n \),
with \( \Omega_n = S_n \times I_n, S_n \) a copy of \( S, \) and \( I_n \) a copy of the unit interval \([0,1] \). Thus \( \Omega_0 \) is separable and locally compact, by virtue of these properties for the spaces \( S \) and \([0,1] \), and taking \( \mathcal{B}_0 \) to be the product \( \sigma \)-algebra on \( \Omega_0 \). Also, \( \Omega_0 \) is metrizable. Therefore, noting that \( \eta_n \to \eta \) in \( \mu_0 \)-measure, it is easily seen that we may apply part (ii) already proved, to assert that \( g(\eta_n) \to g(\eta) \) in \( \mu_0 \)-measure, which implies (2.1).

REMARK 2.1. (i) It is possible to relax the assumption of separability in Theorem 2.1, at the expense of greatly complicating
the formulation and tools. This entails replacing the Borel $\sigma$-algebra $\mathcal{B}$ with a suitable sub-$\sigma$-algebra, considering non-Borel measures, and utilizing a further extension of Skorokhod's theorem by Wichura (1970) to arbitrary metric spaces. For discussion of convergence in distribution and probability in this setting, see Gaenssler (1983), Chapter 3.

(ii) It would be of interest also to develop an analogous theorem for convergence of $g(\xi_n)$ to $g(\xi)$ almost surely, given $\xi_n \rightarrow \xi$ almost surely ($\mathbb{P}$). However, a preliminary investigation suggests the need for a refinement of Luzin's theorem. This will be pursued elsewhere.

From Remark 1.1 (i), (ii) we immediately have

**COROLLARY 2.1.** Let $(S, \rho)$ be a separable and locally compact metric space, with corresponding Borel $\sigma$-algebra $\mathcal{B}$. Let $\{P_n\}$ and $P$ be probability measures on $S$ such that either $\{P_n\}$ is equicontinuous at 0 or $\{P_n\}$ is uniformly absolutely continuous with respect to $P$. Then, for every $S$-measurable function $g: S \rightarrow \mathbb{R}$, we have:

(i) $P_n g^{-1} \Rightarrow P g^{-1}$

and

(ii) $g(\xi_n) \Rightarrow g(\xi)$, whenever $\{\xi_n\}$ and $\xi$ are measurable mappings of some $(\Omega, \mathcal{A}, \mathbb{P})$ into $S$ with $\xi_n \Rightarrow \xi$.

The next result is of special interest in connection with problems such as the statistical application discussed at the end of Section 1. We denote by $\lambda$ the Lebesgue measure on $([0,1], \mathcal{B})$. For any df $G$ on $\mathbb{R}$, put $G^{-1}(t) = \inf\{x: G(x) \geq t\}, t \in (0,1)$. 

-7-
COROLLARY 2.2. Let \( g: \mathbb{R} \to \mathbb{R} \) be Borel-measurable. Let \( \{G_n\} \) and \( G \) be df's on \( \mathbb{R} \) such that \( G_n \to G \) and \( \{G_n\} \) is weakly contiguous to \( G \) at a Luzin sequence for \( g \) at \( G \). Then \( g \circ G_n^{-1} \) converges to \( g \circ G^{-1} \) in Lebesgue measure, i.e., for every \( \epsilon > 0 \),

\[
\lim_{n \to \infty} \lambda\{t: |g \circ G_n^{-1}(t) - g \circ G^{-1}(t)| > \epsilon \} = 0.
\]

PROOF. We apply Theorem 2.1 with \( S = \mathbb{R} \) and \( (\mathcal{A}, \lambda, \mathbb{P}) = ([0,1], \mathcal{B}, \lambda) \). Now, by Lemma 1.5.6 of Serfling (1980), the convergence \( G_n \to G \) implies that the set \( \{t: G_n^{-1}(t) \neq G^{-1}(t), n \to \infty\} \) has at most countably many elements. That is, the sequence of r.v.'s \( \xi_n(t) = G_n^{-1}(t) \) defined on \( ([0,1], \mathcal{B}) \) converges a.s. \( \lambda \) and hence in \( \lambda \)-measure to the r.v. \( \xi(t) = G^{-1}(t) \). And, of course, the df's of \( \{\xi_n\} \) and \( \xi \) are simply \( \{G_n\} \) and \( G \), respectively. Thus (2.4) follows by part (ii) of Theorem 2.1.

Statistical applications of Corollary 2.2 are as follows. Let \( X_1, X_2, \ldots \) be independent r.v.'s on \( \mathbb{R} \) with common df \( F \), and define \( F_n(x) = n^{-1} \sum_{i=1}^{n} \mathbb{1}(X_i \leq x), x \in \mathbb{R} \). By the Glivenko-Cantelli theorem it follows that with probability \( 1 \) \( \{F_n(\cdot)\} \) is a sequence of df's satisfying \( F_n \to F \). With this fact and Remark 1.1 (iv), it follows that with probability \( 1 \) \( \{F_n(\cdot)\} \) is a sequence of df's satisfying the requirements of Corollary 2.2 with \( G_n = F_n \) and \( G = F \). Thus, for any Borel-measurable \( g: \mathbb{R} \to \mathbb{R} \), we have: with probability \( 1 \), \( g \circ F_n^{-1} \) converges to \( g \circ F^{-1} \) in Lebesgue measure, i.e., \( \lambda\{t: |g \circ F_n^{-1}(t) - g \circ F^{-1}(t)| > \epsilon\} = 0 \), each \( \epsilon > 0 \). This result is precisely (with
different notation) Lemma 2.1 of van Zwet (1980), which he employs instrumentally in establishing strong convergence of statistics of the form  \[ T_n = \int_0^1 g \circ F_n^{-1}(t) J_n(t) \, dt, \] under suitable conditions on \( \{J_n\} \) and \( F \). Extensions of this work to a much broader class of statistics are made possible by the generalization of van Zwet's lemma given by Theorem 2.1 (ii); see Helmers, Janssen and Serfling (1985).

Acknowledgment. I am greatly indebted to my colleague Alan F. Karr for extensive and very helpful discussions on the issues underlying this development.

Statistics and Probability Program
Arlington, Virginia 22217

Convergence of $g(\xi_n)$ to $g(\xi)$ is considered when $\xi_n \rightarrow \xi$ in distribution or in probability, without the usual restriction that $g$ be continuous a.s. under the distribution of $\xi$. It is shown that the convergence $g(\xi_n) \rightarrow g(\xi)$ holds for arbitrary Borel-measurable $g$, if in addition to the assumed convergence $\xi_n \rightarrow \xi$, the corresponding measures $\{P_n\}$ of $\{\xi_n\}$ are "contiguous" to the measure $P$ of $\xi$ in a certain very weak sense. Some statistical applications are indicated.
