David Siegmund
Stanford University

For normal random walks $S_1, S_2, \cdots$, formed from independent, identically distributed random variables $X_1, X_2, \cdots$, we determine the asymptotic behavior under regularity conditions of

$$P(S_n > mg(n/m)) \text{ for some } n < m \int S_m = m\xi_0, \quad U_m = m\lambda_0, \quad \xi_0 < g(1),$$

where $U_m = X_1^2 + \cdots + X_m^2$. The result is applied to a normal change-point problem to approximate null distributions of test statistics and to obtain approximate confidence sets for the change-point.

AMS 1980 subject classifications. Primary 60F10, 60J15. Secondary 62F03.

Key words and phrases. Boundary crossing probabilities, change-point, normal random walk.
1. Introduction. A method of developing approximations for boundary crossing probabilities which has received some attention of late is that of writing the probability as an expectation of a conditional boundary crossing probability given an appropriate random variable, and then developing an approximation for the conditional probability. Such a method has been used with some degree of success, as measured by the accuracy of the approximations, by Siegmund (1982, 1985, 1986), Hu (1985), and James, James, and Siegmund (1985).

Let \( X_1, X_2, \ldots \) be independent, identically distributed \( N(\mu, \sigma^2) \) random variables, with \( S_n = X_1 + \cdots + X_n \) and \( U_n = X_1^2 + \cdots + X_n^2 \). Given a function \( g(t) \), \( 0 < t \leq 1 \), and \( m \geq 1 \), let \( r \) be the possibly defective stopping time

\[
r = r_m = \inf \{ n \geq 1 : S_n > mg(n/m) \}
\]

Siegmund (1982) studied the asymptotic behavior of the conditional probabilities

\[
P(r < m \mid S_m = m\xi_0), \quad \xi_0 < g(1),
\]

and used the results to approximate the tail probability of the Smirnov statistic and the power function of repeated significance tests for a normal mean when \( \sigma^2 \) is known. In this paper, we extend Siegmund's method to study the asymptotic order of the conditional probabilities

\[
P(r < m \mid S_m = m\xi_0, \ U_m = m\lambda_0), \quad \xi_0 < g(1),
\]  

and apply the result to some change-point problems.

Our main result is stated and proved in the next section, after some preliminary lemmas. The proof uses a likelihood ratio argument, but we believe the result could also be obtained using the method of Woodroofe (1982, Chapter 8). On the other hand, the method of mixtures of likelihood ratios (cf. Lai and Siegmund, 1977) and the method of Siegmund (1985, Theorem 9.54; see also Hu, 1985), which seem particularly simple in certain related problems, appear to be difficult to adapt to the present situation.

Our motivation for studying the conditional probabilities (1.1) comes from our investigation of the following change-point problem: Let \( X_1, \cdots, X_m \) be independent random variables with \( X_i \sim N(\mu_i, \sigma^2) \), and suppose we wish to test the hypothesis of no change in mean, \( H_0 : \)
\[ \mu_1 = \cdots = \mu_m, \] versus the alternative of a single change, \( H_1 : \mu_1 = \cdots = \mu_j \neq \mu_{j+1} = \cdots = \mu_m \) for some \( j \in \{1, \ldots, m-1\} \). We can then use the theorem of the next section to obtain approximations for the significance levels of several tests of \( H_0 \), as well as to obtain likelihood-based confidence sets for the change-point \( j \). These applications are given in Section 3.

2. Asymptotic conditional boundary crossing probabilities. Throughout this section, the following assumptions and definitions will hold. \( X_1, \ldots, X_n \) are independent, identically distributed normal random variables, without loss of generality assumed to be \( N(0, 1) \), with \( S_n = X_1 + \cdots + X_n \) and \( U_n = X_1^2 + \cdots + X_n^2 \), \( n = 1, 2, \ldots, m \). The real-valued function \( g \), defined on \( [0, 1] \), has two continuous derivatives. For a fixed \( \xi_0 < g(1) \), there exists a unique point \( t^* \in (0, 1) \) which minimizes the function

\[ h(t) = \frac{g(t) - \xi_0 t}{(t(1-t))^{1/2}} \]
and further satisfies \( h(t^*) > 0 \), \( \liminf_{t \to 0} h(t) > h(t^*) \), and \( h''(t^*) > 0 \). The stopping time \( r = r_m \) is defined by

\[ r = \inf \{ n \leq m : S_n \geq mg(n/m) \}; \]
we let \( r = +\infty \) if the defining set is empty. Let \( \lambda_0 \) be such that \( \lambda_0 > g^2(t^*)(t^*)^{-1} + (g(t^*) - \xi_0)^2(1-t^*)^{-1} \), and define \( \mu \) and \( \sigma^2 \) by \( \mu = g(t^*)/t^* \) and \( \sigma^2 = \lambda_0 - g^2(t^*)(t^*)^{-1} - (g(t^*) - \xi_0)^2(1-t^*)^{-1} \). Let \( \xi = m\xi_0 \) and \( \lambda = m\lambda_0 \). Finally, for any \( z \in IR \) and \( y > 0 \), we let

\[ P_{z,y}^{(m)}(A) = P(A \mid S_m = z, U_m = y) \]
for \( A \) belonging to the \( \sigma \)-field generated by \( X_1, \ldots, X_m \).

It can be seen that \( \sigma^2 = \lambda_0 - \xi_0^2 - h^2(t^*) \), which in turn implies that \( \lambda_0 > \xi_0^2 \) and \( \sigma^2/(\lambda_0 - \xi_0^2) < 1 \). Note also that the condition \( h'(t^*) = 0 \) implies \( \mu - g'(t^*) = (\mu - \xi_0)/(2(1-t^*)) \). Since \( h(t^*) > 0 \), this implies \( \mu - g'(t^*) > 0 \). It can also be shown that the conditions on \( h \) imply that \( 1 + 2g''(t^*)t^*(1-t^*)(\mu - g'(t^*))^{-1} > 0 \). Thus, the terms that appear in (2.6) in the statement of the theorem below are all well-defined, with the factor \( \sigma^2/(\lambda_0 - \xi_0^2) \) taking on a value between 0 and 1.

The following two lemmas are technical and will be used in the proof of the theorem.
Lemma 1. Assume \( a_m \to \infty \) with \( a_m = o(m^{1/2}) \), and let \( b_m = m^{1/2} \log m \) and \( I_m = (mt^* - a_m m^{1/2}, mt^* + a_m m^{1/2}) \). The following bounds all hold as \( m \to \infty \):

(a) \( \max_{1 \leq n \leq m-1} P_{\xi, \lambda}^{(m)} (S_n \geq mg (n/m)) = O \left\{ (\sigma^2/(\lambda_0 - \xi_0^2))^{(m-3)/2} \right\} \);

(b) \( \sum_{n \in I_m} P_{\xi, \lambda}^{(m)} (S_n \geq mg (n/m)) = O \left\{ (\sigma^2/(\lambda_0 - \xi_0^2))^{(m-3)/2} \right\} \);

(c) \( P_{\xi, \lambda}^{(m)} (|r/m - t^*| \geq a_m m^{-1/2}) = O \left\{ (\sigma^2/(\lambda_0 - \xi_0^2))^{(m-3)/2} \right\} \);

(d) \( P_{\xi, \lambda}^{(m)} (|r/m - t^*| < a_m m^{-1/2}, S_r - mg (r/m) \geq b_m) = o \left\{ (\sigma^2/(\lambda_0 - \xi_0^2))^{(m-3)/2} \right\} \); and

(e) for each fixed \( \epsilon > 0 \), uniformly for \( n \) and \( r \) such that \( |n - mt^*| \leq a_m m^{1/2} \) and \( 0 \leq r \leq b_m \),

\[
P_{\xi, \lambda}^{(m)} (|U_n/m - (\sigma^2 + \mu^2) t^*| > \epsilon \mid S_n = mg (n/m) + r) = o(1).
\]

Proof. (a) The conditional density of \( S_n \) given \( S_m = \xi \) and \( U_m = \lambda \), which is easily obtained via the conditional joint density of \( S_n \) and \( U_n \), is given by

\[
f_{S_n} (x \mid S_m = \xi, U_m = \lambda) = \left( \frac{m}{\pi n (m - n)} \right)^{1/2} \frac{\Gamma((m - 1)/2)}{\Gamma((m - 2)/2)} \cdot \left( \lambda - \frac{\xi^2}{m} \right)^{-(m-3)/2} \left( \lambda - \frac{\xi^2}{m} - \frac{x^2}{m - n} \right)^{(m-4)/2}
\]

if \( x^2 n^{-1} + (\xi - x)^2 (m - n)^{-1} < \lambda \) (and \( = 0 \) otherwise). After integrating and changing variables, we obtain

\[
P_{\xi, \lambda}^{(m)} (S_n \geq mg (n/m)) = \frac{\Gamma((m - 1)/2)}{\pi n^{1/2} \Gamma((m - 2)/2)} \int_{B_n} (1 - y^2)^{(m-4)/2} dy,
\]

where \( B_n = \{ y : |y| \leq 1, y \geq (\lambda_0 - \xi_0^2)^{-1/2} h(n/m) \} \). Now if \( 0 < a < 1 \) we can show, by a change of variables \( (x = y^2) \) and appropriate bounding of the integrand, that

\[
\int_a^1 (1 - y^2)^{(m-4)/2} dy \leq \frac{(1 - a^2)^{(m-2)/2}}{a(m - 2)}.
\]

Stirling's formula for the gamma function implies \( \Gamma((m - 1)/2) / \Gamma((m - 2)/2) \sim (m/2)^{1/2} \). Thus, it follows from the fact that \( h(n/m) \geq h(t^*) \), together with (2.1) and (2.2), that

\[
P_{\xi, \lambda}^{(m)} (S_n \geq mg (n/m)) \leq Km^{-1/2} \frac{(\lambda_0 - \xi_0^2 - h^2(n/m))}{\lambda_0 - \xi_0^2}^{(m-3)/2}
\]

for some \( K > 0 \) and all \( m \geq 3 \) and \( n \) such that \( h^2(n/m) < \lambda_0 - \xi_0^2 \) (the bound is 0 otherwise).

Part (a) now follows from the relations \( \sigma^2 = \lambda_0 - \xi_0^2 - h^2(t^*) \) and \( h(n/m) \geq h(t^*) \).
(b) and (c). Note that

$$P_{t, \lambda}(p \geq a_m m^{-1/2}) \leq \sum_{n \in I_m} P_{t, \lambda}(S_n \geq mg(n/m)),$$

and that (2.3) implies

$$(2.4) \quad P_{t, \lambda}(S_n \geq mg(n/m)) \leq Km^{-1/2} \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \left( \frac{\lambda_0 - \xi_0^2 - h^2(n/m)}{\lambda_0 - \xi_0^2 - h^2(t^*)} \right)^{(m-3)/2}.$$

Both (b) and (c) will follow by developing bounds for appropriate sums of the last factor above. By the assumptions on $h$, this factor will be of exponentially small order in $m$ if $n/m$ lies outside any fixed neighborhood of $t^*$; thus, for any fixed $\delta > 0$, we may restrict attention to $n$ such that $|n/m - t^*| < \delta$. But Taylor's series expansions on $\log(1 + x)$, to one derivative, and $h(t)$ around $t^*$, to two derivatives, yield the existence of $K_0 > 0$ and $\delta > 0$ such that

$$\left( \frac{\lambda_0 - \xi_0^2 - h^2(n/m)}{\lambda_0 - \xi_0^2 - h^2(t^*)} \right)^{(m-3)/2} < \exp \left( -mK_0(n/m - t^*)^2 \right)$$

for $n$ such that $|n/m - t^*| < \delta$. Parts (b) and (c) follow by summing these bounds over $n$ in $I_m$ and $I^*_m$ and bounding the sums appropriately by integrals.

(d) By a process similar to that used to obtain (2.4), we have that

$$P_{t, \lambda}(p \geq a_m m^{-1/2}, S_r - mg(r/m) \geq b_m) \leq \sum_{n \in I_m} P_{t, \lambda}(S_n \geq mg(n/m) + b_m)$$

and for some $K' > 0$, all $m \geq 3$, and all $n$ such that $[h(n/m) + b_m/(m - n)]^{1/2} < \lambda_0 - \xi_0^2$,

$$P_{t, \lambda}(S_n \geq mg(n/m) + b_m) \leq Km^{-1/2} \left( \frac{\lambda_0 - \xi_0^2 - h^2(n/m) + b_m/m}{\lambda_0 - \xi_0^2 - h^2(t^*)} \right)^{(m-3)/2}$$

$$\leq K'm^{-1/2} \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \left( \frac{\lambda_0 - \xi_0^2 - h^2(n/m) + b_m/m}{\lambda_0 - \xi_0^2 - h^2(t^*)} \right)^{(m-3)/2}$$

$$\leq K'm^{-1/2} \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \left( 1 - \frac{4b_m^2}{\sigma^2 m^2} \right)^{(m-3)/2},$$

where the last inequality uses the fact that $h(n/m) \geq h(t^*)$. Part (d) now follows by using the relation $1 - a \leq e^{-a}$ for $0 \leq a \leq 1$. 

(2.5)
\[ P_{\xi,\lambda}^{(m)} \left( |U_n/m - (\sigma^2 + \mu^2)t|^2 > \epsilon \mid S_n = x, S_m = \xi, U_m = \lambda \right) \leq \frac{1}{\epsilon^2} \left[ \text{Var} \left( \frac{U_n}{m} \mid S_n = x, S_m = \xi, U_m = \lambda \right) + \{E \left( \frac{U_n}{m} \mid S_n = x, S_m = \xi, U_m = \lambda \right) - (\sigma^2 + \mu^2)t^* \}^2 \right]. \]

Conditionally, \( U_n \) is a linear function of a beta-distributed random variable. In fact it can be shown that the random variable
\[ V = \frac{U_n - S_2/n}{U_m - S_2^2/n - (S_m - S_n)^2/(m-n)}, \]
whose numerator is one of two independent chi-squareds making up the denominator, has a beta distribution with parameters \( (n-1)/2 \) and \( (m-n-1)/2 \) and is independent of the vector \((S_n, S_m, U_m)\). Therefore,
\[ E(U_n \mid S_n = x, S_m = \xi, U_m = \lambda) = \frac{x^2}{n} + \left( \lambda - \frac{(\xi - x)^2}{m - n} - \frac{x^2}{n} \right) \frac{(n-1)}{(m-2)} \]

and
\[ \text{Var}(U_n \mid S_n = x, S_m = \xi, U_m = \lambda) = \frac{2}{m(m-2)} \left( \lambda - \frac{(\xi - x)^2}{m - n} - \frac{x^2}{n} \right)^2 \frac{(n-1)(m-n-1)}{m(m-2)}. \]

Part (e) now follows from (2.5) and the above by algebra.

**Lemma 2.** For each \( \epsilon > 0 \),

(a) \( P_{\xi,\lambda}^{(m)} \left( |S_r/m - \mu^*| > \epsilon, \ r < m \right) = o \left\{ (\sigma^2/(\lambda_0 - \xi_0^2))^{(m-3)/2} \right\} \) and

(b) \( P_{\xi,\lambda}^{(m)} \left( |U_r/m - (\sigma^2 + \mu^2)t^*| > \epsilon, \ r < m \right) = o \left\{ (\sigma^2/(\lambda_0 - \xi_0^2))^{(m-3)/2} \right\}. \)

**Proof.** Let \( a_m = \log m \). Applying first Lemma 1(c) and then the triangle inequality, we have
\[ \text{LHS}(a) = P_{\xi,\lambda}^{(m)} \left( |S_r/m - \mu^*| > \epsilon, \ r|m-t^*| < a_m m^{-1/2} \right) + o \left( \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \right) \]
\[ \leq P_{\xi,\lambda}^{(m)} \left( S_r - mg(r/m) > \frac{me}{2}, \ |r|m-t^*| < a_m m^{-1/2} \right) \]
\[ + P_{\xi,\lambda}^{(m)} \left( |g(r/m) - \mu^*| > \frac{\epsilon}{2}, \ |r|m-t^*| < a_m m^{-1/2} \right) + o \left( \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \right). \]

The second summand on the right-hand side above is null for \( n \) sufficiently large, since \( g \) is continuous and \( g(t^*) = \mu^* \). The first summand can be handled by Lemma 1(d), thus completing the proof of (a).
Apply parts (c) and (d) of Lemma 1 to get

\[ \text{LHS}(b) = P^{(m)}_{\xi, \lambda} \left( |U_r/m - (\sigma^2 + \mu^2) t^*| > \epsilon, S_r - \mu t^* \leq b_m, |r/m - t^*| < a_m m^{-1/2} \right) \]

\[ + o \left\{ \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \right\}. \]

Now decompose the above event according to the value of \( r \), letting \( I_m \) be the interval \((m t^* - a_m m^{1/2}, m t^* + a_m m^{1/2})\):

\[ \text{LHS}(b) \leq \sum_{n \in I_m} P^{(m)}_{\xi, \lambda} \left( |U_n/m - (\sigma^2 + \mu^2) t^*| > \epsilon, 0 \leq S_n - mg(n/m) \leq b_m \right) \]

\[ + o \left\{ \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \right\}. \]

\[ \leq \sum_{n \in I_m} P^{(m)}_{\xi, \lambda} \left( S_n \geq mg(n/m) \right) P^{(m)}_{\xi, \lambda} \left( |U_n/m - (\sigma^2 + \mu^2) t^*| > \epsilon \mid 0 \leq S_n - mg(n/m) \leq b_m \right) \]

\[ + o \left\{ \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \right\}. \]

Part (b) now follows by applying first Lemma 1(e) and then Lemma 1(b).

Remark 1. We will show in the course of the proof of our main theorem that \( P^{(m)}_{\xi, \lambda}(r < m) > K \{\sigma^2/(\lambda_0 - \xi_0^2)\}^{(m-3)/2} \) for some \( K > 0 \). Then Lemmas 1(c) and 2 will give us convergence of \( r/m, S_r/m, \) and \( U_r/m \) to \( t^*, \mu t^*, \) and \( (\sigma^2 + \mu^2)t^* \) in conditional \( P^{(m)}_{\xi, \lambda} \)-probability given \( \{r < m\} \), i.e. for each \( \epsilon > 0 \)

\[ P^{(m)}_{\xi, \lambda} \left( |r/m - t^*| > \epsilon \mid r < m \right) \to 0, \]

\[ P^{(m)}_{\xi, \lambda} \left( |S_r/m - \mu t^*| > \epsilon \mid r < m \right) \to 0, \]

and

\[ P^{(m)}_{\xi, \lambda} \left( |U_r/m - (\sigma^2 + \mu^2)t^*| > \epsilon \mid r < m \right) \to 0. \]

Remark 2. Formula (2.1) shows that the marginal probability \( P^{(m)}_{\xi, \lambda}(S_n \geq mg(n/m)) \) is maximized by that \( n \) which minimizes \( h(n/m) \), i.e. by some \( n \) not far from \( mt^* \). When \( m \) is large, then, it would seem reasonable that if the partial sum process were to cross the curve at all, it would do it for \( n \) near \( mt^* \). We see from Remark 1 that this holds.
Theorem. Let \( \nu \) be the function defined for \( t > 0 \) by
\[
\nu(t) = 2t^{-2} \exp \left\{ -2 \sum_{n=1}^{\infty} n^{-1} \Phi(-tn^{1/2}/2) \right\},
\]
where \( \Phi \) is the standard normal distribution function. Then, as \( m \to \infty \),
\[
P_{\xi,\lambda}^{(m)}(r < m) \sim \nu \left\{ \frac{2(\mu - g'(t^*))}{\sigma} \right\} \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{\frac{(m-3)/2}{2}} \left( 1 + \frac{2g''(t^*)t^*(1-t^*)}{\mu - g'(t^*)} \right)^{-1/2}.
\]

Remark 3. The function \( \nu \) can be evaluated either directly by numerical computation or approximately, at least in the range \( 0 < t \leq 2 \), from the local expansion
\[
\nu(t) = \exp(-\rho t) + o(t^2), \quad t \to 0,
\]
where \( \rho \) is a numerical constant which is approximately equal to .583. See Siegmund (1985, Ch. X).

Proof. Let \( P_{\xi,\lambda}^{(m)} \) denote the restriction of \( P_{\xi,\lambda}^{(m)} \) to the \( \sigma \)-field generated by \( X_1, \ldots, X_n \). Let \( \xi = m\mu \) and \( \lambda_1 = m(\sigma^2 + \mu^2) \). The idea of the proof is to use a likelihood ratio argument, based on the likelihood ratio of \( P_{\xi,\lambda}^{(m)} \) with respect to \( P_{\xi,\lambda}^{(m)} \). The values of \( \xi_1 \) and \( \lambda_1 \) are chosen because of the approximately equivalent local behavior of the pre-\( r \) process under \( P_{\xi,\lambda}^{(m)} \) and, conditionally, under \( P_{\xi,\lambda}^{(m)} \) given \( \{ r < m \} \). In fact, given \( \{ r < m \} \), Remark 1 tells us that \( S_r/r \to \mu \) and \( U_r/r \to \sigma^2 + \mu^2 \) in \( P_{\xi,\lambda}^{(m)} \)-probability.

Let \( L_n \) denote the likelihood ratio of the absolutely continuous part of \( P_{\xi,\lambda,n}^{(m)} \) relative to \( P_{\xi,\lambda_1,n}^{(m)} \). A straightforward calculation shows that for \( n \leq m - 2 \),
\[
L_n = \left( \frac{\lambda - U_n - (\xi - S_n)^2/(m - n)}{\lambda_1 - U_n - (\xi_1 - S_n)^2/(m - n)} \right)^{(m-n-3)/2} \left( \frac{\lambda_1 - \xi_1^2/m}{\lambda - \xi^2/m} \right)^{(m-3)/2}
\]
if \( \lambda - U_n - (\xi - S_n)^2/(m - n) > 0 \) and \( \lambda - U_n - (\xi - S_n)^2/(m - n) > 0 \), and \( L_n = 0 \) if \( \lambda - U_n - (\xi - S_n)^2/(m - n) \leq 0 \) or \( \lambda - U_n - (\xi_1 - S_n)^2/(m - n) \).

By a slight generalization of Wald’s likelihood ratio identity (see e.g. Siegmund 1985, p. 13),
\[
P_{\xi,\lambda}^{(m)}(r \leq m - 2) = \int_{\{r \leq m - 2\} \cap A} L_r dP_{\xi,\lambda}^{(m)} + P_{\xi,\lambda}^{(m)}(\{ r \leq m - 2 \} \cap A^c),
\]
where \( A = \{ \lambda_1 - U_r - (\xi_1 - S_r)^2/(m - r) > 0 \} \). By Lemma 1(a), it is sufficient to show that the integral in (2.7) is asymptotically equivalent to the right-hand side of (2.6) and the final probability in (2.7) is of smaller asymptotic order.

Upon substitution of the likelihood ratio, the integral in (2.7) becomes

\[
\left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \int_{(r \leq m-2) \cap A} \left( \frac{\lambda - U_r - (\xi - S_r)^2/(m - r)}{\lambda_1 - U_r - (\xi_1 - S_r)^2/(m - r)} \right)^{(m-r-3)/2} dP_{\xi_1, \lambda_1}.
\]

Law of large numbers arguments indicate that under \( P_{\xi_1, \lambda_1} \), as \( m \to \infty \),

\[
\frac{r}{m} \to t^*, \quad \frac{S_r}{m} \to \mu t^*, \quad \text{and} \quad \frac{U_r}{m} \to (\sigma^2 + \mu^2) t^*,
\]

so that

\[
m^{-1} \left( \frac{\lambda - U_r - (\xi - S_r)^2}{m - r} \right) \to \sigma^2(1 - t^*), \quad m^{-1} \left( \frac{\lambda_1 - U_r - (\xi_1 - S_r)^2}{m - r} \right) \to \sigma^2(1 - t^*).
\]

Since \( \log(1 + z) = z + O(z^2) \) as \( z \to 0 \), we have

\[
\frac{\lambda - U_r - (\xi - S_r)^2}{\lambda_1 - U_r - (\xi_1 - S_r)^2} = \exp \left[ \frac{\lambda - \lambda_1 - \{\xi^2 - \xi_1^2 - 2S_r(\xi - \xi_1)\}/(m - r)}{\lambda_1 - U_r - (\xi_1 - S_r)^2} \right] + O_p \left( \left( \frac{\lambda_0 - \sigma^2 - \mu^2 - 2(\xi_0 - \mu)S_r/m}{1 - r/m} \right)^2 \right).
\]

Letting \( R_m \) be the excess over the boundary, i.e. \( R_m = S_r - mg(r/m) \), and using a Taylor expansion on \( g \) at \( t^* \), we get

\[
S_r = R_m + m \left\{ g(t^*) + g'(t^*) (r/m - t^*) + \frac{g''(t^*)}{2} (r/m - t^*)^2 + \epsilon (r/m) (r/m - t^*)^2 \right\},
\]

where \( \epsilon(t) \to 0 \) as \( t \to t^* \). To obtain the limiting joint distribution of \( R_m \) and \( m^{1/2}(r/m - t^*) \) we must appeal to an appropriate nonlinear renewal theorem for the conditional process governed by \( P_{\xi_1, \lambda_1}^{(m)} \). For an intuitive discussion of nonlinear renewal theory which leads one to the correct limiting joint distribution, see Siegmund (1986, Appendix 2 and Lemma 2.16). Hu (1985, Chapter 4, Theorem 10) has proved a general result which provides a rigorous justification.

The upshot is that \( R_m \) and \( m^{1/2}(r/m - t^*) \) converge in distribution and are asymptotically independent under \( P_{\xi_1, \lambda_1}^{(m)} \); the limiting distributions will be seen below. This, together with
some algebra, means that the right hand side of (2.10) can be written as
\[
\exp\left\{ \frac{2(\xi_0 - \mu)(R_m + mg''(t^*)(\tau/m - t^*)^2/2 + mc(\tau/m)(\tau/m - t^*)^2)}{(1 - r/m)(\lambda_1 - U_r - (\xi_1 - S_r)^2/(m - r))} - O_p(m^{-2}) \right\}.
\]

If we insert this in the integrand, (2.8) becomes
\[
\left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \int_{\{r \leq m-2\} \cap A} \exp\left\{ \frac{(m - r - 3)(\xi_0 - \mu)(R_m + mg''(t^*)(\tau/m - t^*)^2/2 + o_p(1))}{(1 - r/m)(\lambda_1 - U_r - (\xi_1 - S_r)^2/(m - r))} + O_p(m^{-1}) \right\} dP_{\xi_1, \lambda_1}^{(m)}.
\]

Application of (2.9) then yields
\[
(2.8) = \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \int_{\{r \leq m-2\} \cap A} \exp\left\{ \frac{2(\xi_0 - \mu)(R_m + mg''(t^*)(\tau/m - t^*)^2/2)}{\sigma^2(1 - t^*)} + o_p(1) \right\} dP_{\xi_1, \lambda_1}^{(m)}.
\]

It follows from (2.9) that
\[
P_{\xi_1, \lambda_1}^{(m)} \left( \tau \leq m - 2, \lambda_1 - U_r - \frac{(\xi_1 - S_r)^2}{m - r} > 0 \right) \rightarrow 1, \quad m \rightarrow \infty,
\]
so that if we may interchange expectation and limit in (2.12), we will be able to evaluate the order of (2.8) by using Hu’s result. This result states that as \( m \rightarrow \infty \)
\[
P_{\xi_1, \lambda_1}^{(m)} \left( \frac{(r - mt^*)(\mu - g'(t^*))}{(mt^*(1 - t^*))^{1/2}} \leq x, R_m \leq y \right) \rightarrow \Phi(x) \cdot \lim_{c \rightarrow \infty} P(R^*_c \leq y),
\]
where \( \Phi \) is the standard normal distribution function and \( R^*_c \) is the excess over the constant boundary \( c \) of a random walk, generated by independent, identically distributed \( N(\mu - g'(t^*), \sigma^2) \) random variables, which is stopped the first time it exceeds \( c \). If \( R \) is a random variable such that \( R^*_c \overset{D}{\rightarrow} R \) as \( c \rightarrow \infty \), then renewal theory (see Siegmund, 1985, Chapter VIII) allows us to calculate
\[
E \exp\left\{ \frac{(\xi_0 - \mu)R}{(1 - t^*)\sigma^2} \right\} = \nu \left\{ \frac{2(\mu - g'(t^*))}{\sigma} \right\},
\]
where we use the fact, noted earlier in this section, that \( \mu - g'(t^*) = (\mu - \xi_0)/(2(1 - t^*)) \). If \( X \) has a chi-squared distribution with one degree of freedom, the remaining factor will have the form
\[
E \exp\left\{ \frac{-g''(t^*)t^*(1 - t^*)}{\mu - g'(t^*)} X \right\} = \left\{ 1 + \frac{2g''(t^*)t^*(1 - t^*)}{\mu - g'(t^*)} \right\}^{-1/2}.
\]
Therefore, we will be able to conclude that the right-hand side of (2.6) is asymptotically equivalent to (2.8) if we can make the exchange of expectation and limit alluded to above.

Fatou's Lemma for convergence in law implies that the right-hand side of (2.6) is an asymptotic lower bound for (2.8). By Lemma 1(c), \( P^{(m)}_{\xi, \lambda} \left( |r/m - t^*| \geq a_m \right) \) is of asymptotically smaller order than this if \( a_m \to \infty \) and \( a_m = o(m^{1/2}) \). The analog of formula (2.7) with \( \{m^{1/2}|r/m - t^*| \geq a_m \} \) in place of \( \{ r \leq m - 2 \} \) then implies that

\[
\int_{\{m^{1/2}|r/m - t^*| \geq a_m \} \cap A} L_r \, dP^{(m)}_{\xi, \lambda} = o \left\{ \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \right\}
\]

Therefore, for any sequence \( \{a_m\} \) such that \( a_m \to \infty \) and \( a_m = o(m^{1/2}) \),

\[
(2.8) \sim \left( \frac{\sigma^2}{\lambda_0 - \xi_0^2} \right)^{(m-3)/2} \int_{\{m^{1/2}|r/m - t^*| < a_m \} \cap A} \left( \frac{\lambda - U_r - (\xi - S_r)^2/(m - \tau)}{\lambda - U_r - (\xi_1 - S_r)^2/(m - \tau)} \right)^{(m-r-3)/2} \, dP^{(m)}_{\xi, \lambda}.
\]

From Lemmas 1 and 2, via Remark 1, we see that for all \( \epsilon > 0 \)

\[
P^{(m)}_{\xi, \lambda} \left( |m^{-1} \left\{ \lambda_1 - U_r - \frac{(\xi_1 - S_r)^2}{m - \tau} \right\} - \sigma^2(1 - t^*)| > \epsilon \ | r \leq m - 2 \right) \to 0,
\]

so that we may replace the event \( A \) in the above by \( \{ (\lambda_1 - U_r - (\xi_1 - S_r)^2/(m - \tau)) / m > \sigma^2(1 - t^*)/2 \} \). We may use the fact that \( \log(1 + z) < z \) if \( z > 0 \) to obtain bounds for the integrand in the right-hand side of (2.13) in the region of integration:

\[
\left( \frac{\lambda - U_r - (\xi - S_r)^2/(m - \tau)}{\lambda_1 - U_r - (\xi_1 - S_r)^2/(m - \tau)} \right)^{(m-r-3)/2} \\
\leq 1 \vee \exp \left[ \frac{(m - r - 3)}{2} \left( \frac{\lambda - \lambda_1 - (\xi^2 - \xi_1^2 - 2S_r(\xi - \xi_1)}/(m - \tau)}{\lambda_1 - U_r - (\xi_1 - S_r)^2/(m - \tau)} \right) \right] \\
\leq 1 \vee \exp \left[ \frac{2(m - r - 3)(\xi_0 - \mu)\{R_m + mg''(t^*)(r/m - t^*)^2/2 + mc(r/m)(r/m - t^*)^2\}}{\sigma^2(1 - t^*)(1 - r/m)} \right] \\
\leq 1 \vee \exp \left[ \frac{m(r/m - t^*)^2(\lambda_0 - \mu)g''(t^*) + 2|e(r/m)|}{\sigma^2(1 - t^*)} \right] \leq \exp(K a_m^2),
\]

for some \( K > 0 \) and \( m \) large enough to make \( a_m / m^{1/2} \) sufficiently small. We may then choose a suitable sequence \( \{a_m\} \), converging sufficiently slowly to \( +\infty \), to allow us to finish the proof of the asymptotic equivalence of (2.8) and the right-hand side of (2.6).
Equation (2.14) also indicates that the final probability in (2.7) is of smaller asymptotic order, because it implies that $P_{\xi, A}^{(m)}(A^c | r \leq m - 2) \to 0$.

As an aid in applying the theorem, we note that if $g$ has two continuous derivatives, then the other conditions on $g$ and $h$ will be satisfied if (i) $t^*$ is the only point at which $h' = 0$, (ii) $h(t^*) > 0$, and (iii) $h''(t^*) > 0$. This will be the case in the examples considered in the next section.

3. Application: Tests and confidence sets for a change-point.

3.1. Approximate significance levels. Let $X_i, i = 1, \cdots, m$, be independent normal random variables with unknown means $\mu_i$ and constant unknown variance $\sigma^2 > 0$. We consider testing the hypothesis of a constant mean against the alternative of a single change-point, i.e. testing $H_0: \mu_1 = \cdots = \mu_m$ versus $H_1$: for some $j \in \{1, \cdots, m-1\}$, $\mu_1 = \cdots = \mu_j \neq \mu_{j+1} = \cdots = \mu_m$.

We will focus here on three tests considered in James, James, and Siegmund (1985): the likelihood ratio test, a Studentized version of a score-like test due to Pettitt (1980) which was introduced for the case of known variance, and a modification of the recursive residuals test proposed by Brown, Durbin and Evans (1975). Approximations to the significance levels of these tests were given, without formal justification, in James, James, and Siegmund (1985). We will now show how the theorem of the last section can be used to obtain these approximations and also obtain approximate confidence sets for the change-point $j$. We first give the test statistics for the three tests being considered.

The generalized likelihood ratio test can be easily shown to be based on the statistic

$$
\max_{1 \leq n \leq m-1} \frac{|S_n - n\bar{X}_m|}{\{n(1 - n/m)\}^{1/2} S},
$$

where $S_n = X_1 + \cdots + X_n$, $\bar{X}_n = (X_1 + \cdots + X_n)/n$, and $S = \{(m^{-1})\sum_{n=1}^{m} (X_n - \bar{X}_m)^2\}^{1/2}$. In the 1985 paper cited above, we considered the larger family of tests based on statistics of the form

$$
T_1 = \max_{m_0 \leq n \leq m_1} \frac{|S_n - n\bar{X}_m|}{\{n(1 - n/m)\}^{1/2} S},
$$

where $1 \leq m_0 < m_1 \leq m - 1$. The use of $T_1$ with $m_0 > 1$ and $m_1 < m - 1$ allows one greater power than that of the likelihood ratio test for values of $j$ near $m/2$, while giving up some
power for small and large $j$ where the change is difficult to detect in any case. If $m_0 = m - m_1$, then the test based on $T_1$ belongs to a general family of tests considered by Deshayes and Picard (1984).

The Studentized version of Pettitt's test is based on the statistic

$$T_2 = \max_{1 \leq n \leq m-1} \frac{|S_n - n\bar{X}_m|}{S}.$$ 

The recursive residuals statistic of Brown, Durbin and Evans is formed, in the case of known variance, by accumulating sums of standardized residuals $Z_n$ of the $X_{n+1}$ from the previous means $\bar{X}_n$, that is

$$Z_n = \{n/(n+1)\}^{1/2}(X_{n+1} - \bar{X}_n), \quad n = 1, 2, \ldots, m-1.$$ 

The $Z_n$ are independent with common distribution $N(0, \sigma^2)$ under $H_0$. In the case of unknown variance, the accumulated sums are Studentized by dividing by the sample standard deviation of the $Z$'s. In James, James, and Siegmund (1985), power considerations lead us to study the statistic obtained by summing the standardized residuals "from the right," so that we base the recursive residuals test on the statistic

$$T_3 = \max_{m_0 \leq n \leq m-1} \frac{|S_n'|}{S_n'^{1/2}},$$ 

where $S_n' = Z_{m-1} + \cdots + Z_{m-n}$ and $S' = ((m-1)^{-1}(Z_1^2 + \cdots + Z_{m-1}^2))^{1/2}$. However, as long as we are only concerned with the significance level, it makes no difference whether the recursive residuals are summed from the right or, as Brown, Durbin, and Evans proposed, from the left. We note also that although we are considering this very simple problem of a change in mean, the null hypothesis distribution of the recursive residuals statistic is in fact the same as in the general regression model of Brown, Durbin, and Evans, the only difference being that there are $m - p$ recursive residuals $Z_n$ instead of $m - 1$, where $p$ is the number of regression parameters.

We will first obtain approximate significance levels for the tests based on $T_1$ and $T_2$. Since the distribution of the process $\{(S_n - n\bar{X}_m)/S, \ n = 0, 1, \ldots, m\}$ does not depend on $(\mu, \sigma^2)$, the process is independent of the complete sufficient statistic $(S_m, U_m)$, by Basu’s theorem.
(Lehmann, 1959, Theorem 5.2). Therefore, starting with the easier to handle $T_2$ we have

$$P(T_2 \geq b) = P_{0,m}^{(m)}(T_2 \geq b) = P_{0,m}^{(m)}(\max_{1 \leq n \leq m-1} |S_n| \geq b).$$

If we assume that $b = b_m = m\zeta$, for some $0 < \zeta < \frac{1}{2}$, then we can apply our theorem with $g(t) \equiv \zeta$, $\xi_0 = 0$, $\lambda_0 = 1$, and $t^* = \frac{1}{2}$ to obtain

$$(3.1) P(T_2 \geq b) \sim 2\nu \left\{\frac{4\zeta}{(1 - 4\zeta^2)^{1/2}}\right\} (1 - 4\zeta^2)^{(m-3)/2}.$$  

An approximate size $\alpha$ test based on $T_2$ can now be obtained by using as critical value $b = m\zeta$, where $\zeta$ makes the right-hand side of (3.1) equal to $\alpha$.

For the modified likelihood ratio test, we have

$$P(T_1 \geq b) = P_{0,m}^{(m)}(T_1 \geq b) = P_{0,m}^{(m)}(\max_{0 \leq n \leq m-1} |S_n| \geq b).$$

Conditioning with respect to the values of $S_{m_1}$ and $U_{m_1}$ and using the Markov property, we have

$$P(T_1 \geq b) = P_{0,m}^{(m)}(\{S_{m_1} \geq b \{m_1 (1 - m_1/m)\}^{1/2}\})$$

$$+ \int \int_{A_{m_1}} P_{0,m}^{(m)}(r < m_1) P_{0,m}^{(m)}(S_{m_1} \in dz, U_{m_1} \in dy),$$

where $r = \inf\{n \geq m_0 : S_n \geq b\{n(1 - n/m)\}^{1/2}\}$ and $A_{m_1}$ is the set of $(z, y)$ such that $|z| < b\{m_1 (1 - m_1/m)\}^{1/2}$ and the $P_{0,m}^{(m)}$-joint density of $S_{m_1}$ and $U_{m_1}$, as a function of $z$ and $y$, is positive.

The first summand in the right-hand side of (3.2) can be calculated exactly, as in (2.1). The theorem can be used to approximate the integrand in the second summand. For this, assume that $b = cm^{1/2}$, $m_0 = mt_0$, $m_1 = mt_1$, $x = m_1z_0$, and $y = m_1y_0$, where $0 < c < 1$, $0 < t_0 < t_1 < 1$, $|x_0| < ct_1^{-1/2}(1 - t_1)^{1/2}$, and $m_1y_0$ is a $P_{0,m}^{(m)}$-possible value of $U_{m_1}$, given $S_{m_1} = m_1z_0$. For $g(t) = c(t^{-1}_{1}(1 - t_1))^{1/2}$, $\xi_0 = x_0$ and $\lambda_0 = y_0$, we obtain

$$t^* = \frac{x_0^2 t_1}{c^2 (1 - t_1)^2 + x_0^2 t_1^2}.$$  

The only hitch in applying the theorem is that $\tau \geq m_0$; a direct application requires $m_0 = 1$. However, this is no problem if $t^* > t_0/t_1$, because in this case it follows from (2.4) that the
$P_{T_1 > b}$-probability of the process's crossing the boundary before $n = m_0$ is of exponentially smaller order than that of crossing before $n - m_1$, so that we may replace $m_0$ by 1. On the other hand, if $t^* < t_0/t_1$, which corresponds to $|x_0| < c t_1^{-1}(1 - t_1)\{t_0(1 - t_0)^{-1}\}^{1/2}$, we can approximate the integrand by 0. This follows again from (2.4), which implies that the integrand will be of exponentially smaller order than other values of the integrand corresponding to $t^* > t_0/t_1$. Therefore, we are led to the approximation

$$P(T_1 > b) \approx \frac{2\Gamma((m - 1)/2)}{\pi^{1/2}\Gamma((m - 2)/2)} \int_0^1 (1 - z^2)^{(m - 4)/2} \, dz$$

$$+ 2c \left(\frac{1 - t_1}{t_1}\right)^{1/2} \int \frac{1}{x_0} \nu \left(\frac{x_0}{t^*(1 - t_1)\sigma} \right) \left(\frac{\sigma^2}{y_0 - x_0^2}\right)^{(m_1 - 3)/2} \cdot P_{S_{m_1}/m_1}^{(m)}(S_{m_1}/m_1, U_{m_1}/m_1 \in d\nu),$$

where $\sigma^2 = \sigma^2(x_0, y_0) = y_0 - c^2 t_1^{-1} + x_2^2 t_1(1 - t_1)^{-1}$ and

$$B = \{(x_0, y_0) : \frac{c^2}{t_1} - \frac{x_2^2 t_1}{1 - t_1} \leq y_0 \leq \frac{1}{t_1} - \frac{x_2^2 t_1}{1 - t_1}, \frac{c(1 - t_1)}{t_1} \left(\frac{t_0}{1 - t_0}\right)^{1/2}$$

$$< x_0 < c \left(\frac{1 - t_1}{t_1}\right)^{1/2}\}.$$

The factor 2 above is due to restriction to positive values of $x$, by symmetry.

A further approximaton can be made upon insertion of the conditional density into the integral, with subsequent utilization of the fact that $U_{m_1}$ is conditionally, given $S_m = 0$, $U_m = m$, and $S_{m_1} = m_1 x_0$, a linear function of a random variable with a beta distribution with parameters $(m_1 - 1)/2$ and $(m - m_1 - 1)/2$, which as $m \to \infty$ with $m_1/m \to t_1$ collapses to a point mass at $t_1$. Following this procedure, we can insert the $P_{S_{m_1}/m_1}$-density of $(S_{m_1}/m_1, U_{m_1}/m_1)$, to wit

$$\frac{(t_1 m_1/(1 - t_1))^{1/2}\Gamma((m - 1)/2)}{\pi^{1/2}\Gamma((m - 1)/2)\Gamma((m - m_1 - 1)/2)}(y_0 - x_0^2)^{(m_1 - 3)/2}[1 - t_1\{y_0 + x_0^2 t_1/(1 - t_1)\}]^{(m - m_1 - 3)/2},$$

make the change of variable (in $y_0$)

$$z = t_1(1 - c^2)^{-1}\{y_0 + x_0^2 t_1(1 - t_1)^{-1} - c^2 t_1^{-1}\},$$

integrate with respect to $z$, and use Stirling's formula to approximate the remaining gamma functions, to show that the double integral appearing above reduces asymptotically to a single
integral in $x_0$. Thus we are led to the approximation

$$P(T_1 \geq b) = \left( \frac{2m}{\pi} \right)^{1/2} \frac{1}{c} \int_c^1 (1 - x^2)^{(m-4)/2} dx$$

(3.3)

$$+ c \left( \frac{2m}{\pi} \right)^{1/2} (1 - c^2)^{(m-4)/2} \int_{c((t_0^{-1} - 1)/(1 - c^2))^{1/2}}^{c((t_1^{-1} - 1)/(1 - c^2))^{1/2}} \frac{1}{z} \left\{ z + \frac{c^2}{(1 - c^2)z} \right\} \, dz.$$

Remark 4. It is easy to see that for each $i = 0, 1, \cdots$

$$\int_c^1 (1 - x^2)^{(m-i)/2} dx = (cm)^{-1}(1 - c^2)^{m-i+2)/2} \{1 + m^{-1}(i - 1 - c^{-2}) + o(m^{-1})\}$$

as $m \to \infty$. Use of this approximation simplifies slightly the computational burden associated with application of (3.3) or (3.4) below. From this expansion it is evident that the first term on the right-hand side of (3.3) is asymptotically of smaller order than the second and mathematically could be neglected. In a number of related problems Siegmund (1985) shows numerically that including this term typically improves the approximation, and hence we have included it for numerical purposes.

Remark 5. It is natural to ask what precise mathematical meaning can be attached to (3.3). As noted in Remark 4, the first integral on the right hand side of (3.3) is asymptotically negligible. With some additional work it can be shown that $P(T_1 \geq b)$ is asymptotically equivalent to the second integral on the right-hand side of (3.3). It suffices to show that for each $x_0 \in (ct_1^{-1}(1 - t_1)(t_0/(1 - t_0))^{1/2}, c((1 - t_1)/t_1)^{1/2})$ the asymptotic behavior of the conditional probability indicated in the Theorem holds uniformly for $y_0$ in a neighborhood of $1 + c^2t_1^{-1}(1 - t_1) - x_0^2t_1(1 - t_1)^{-1}$ of width $a_m/m^{1/2}$, where $a_m \to \infty$, together with appropriate uniformity in Lemma 1. The details are tedious and have been omitted.

The procedure in studying $T_3$ is similar to that of $T_1$. Starting with sufficiency arguments, we have

$$P(T_3 \geq b) = P(T_3 \geq b \mid (S')^2 = 1) = P(\{S_{m-1}' \geq b(m - 1)^{1/2} \mid (S')^2 = 1\}$$

$$+ \int_{-b(m-1)^{1/2}}^{b(m-1)^{1/2}} P(T_3 \geq b \mid S_{m-1}' = x, (S')^2 = 1) P(S_{m-1}' \in dx \mid (S')^2 = 1).$$

The first summand on the right-hand side above can be calculated exactly from the conditional density. The last summand can be approximated by using the theorem to approximate the integrand. In this case, we assume $b = c(m - 1)^{1/2}$, $x = (m - 1)x_0$, and $m_0 = (m - 1)t_0$, where
\[0 < c < 1, \ |x_0| < c, \text{ and } 0 < t_0 < 1, \text{ and apply the theorem with } g(t) = ct^{1/2}, \xi_0 = x_0, \lambda_0 = 1, \text{ and } t^* = x_0^2/c^2. \]

Calculations similar to those done for the likelihood ratio test then lead to the approximation

\[
P(T_3 \geq b) \approx \left\{ \frac{2(m-1)}{\pi} \right\}^{1/2} \int_0^1 (1 - x^2)^{(m-4)/2} dx \\
+ c \left\{ \frac{2(m-1)}{\pi} \right\}^{1/2} (1 - c^2)^{(m-4)/2} \int_{c/(1-c^2)^{1/2}}^{c/(1-c^2)^{1/2}} z^{-1} \nu(z) dz.
\]

(3.4)

Some comments on the numerical accuracy of the above approximations can be found in James, James, and Siegmund (1985).

3.2. Confidence sets for the change-point. Our theorem can be used to obtain approximate, likelihood-based confidence sets for \(j\), assuming that it exists. The method extends that of Siegmund (1986, §3.5), who considered the case of known variance.

Suppose \(X_1, \cdots, X_m\) are independent, with \(X_1, \cdots, X_j\) independent, identically distributed \(N(\mu_1, \sigma^2)\) and \(X_{j+1}, \cdots, X_m\) independent, identically distributed \(N(\mu_2, \sigma^2)\) for some \(1 \leq j \leq m-1, \mu_1 \neq \mu_2, \text{ and } \sigma^2 > 0\) unknown. To test \(H: j = \rho\) versus \(K: j \neq \rho\), the likelihood ratio test can be based on the statistic

\[T_\rho = \max_{k \neq \rho} \frac{W_k - W_\rho}{\sum_{i=1}^m (X_i - \bar{X}_m)^2 - W_\rho},\]

where \(W_k = (S_k - k\bar{X}_m)^2 / \{k(1 - k/m)\}\). Under \(H_\rho\), the distribution of \(T_\rho\) depends only on \(\rho\) and \(\delta/\sigma = (\mu_2 - \mu_1)/\sigma\), and if we actually wanted to perform the test, or obtain a confidence set based on the family of such tests, we would need to find \(c = c_\alpha\) such that \(\alpha = \sup\{P_{\rho, \delta/\sigma}(T_\rho \geq c) : \delta/\sigma \neq 0\}\). This problem seems impracticable. However, since \(T_\rho\) is stochastically independent of \(S_m\) we do have

\[P_{\rho, \delta/\sigma}(T_\rho \geq c) = P_{\rho, \delta/\sigma}(T_\rho \geq c | S_m = 0),\]

which has the effect of eliminating \(\bar{X}_m\) from the expression for \(T_\rho\) and putting it as a conditioner.

In the spirit of Siegmund (1986, §3.5), we can then think of performing the test conditionally by conditioning first on \(S_\rho\), which eliminates the dependence on \(\delta/\sigma\), and then on \(U_\rho\) and
That is, we attempt to find $c = c(\alpha, \rho, \xi, \lambda_1, \lambda_2)$ such that

$$\alpha = P_\rho(T_\rho \geq c \mid S_\rho = \xi, S_m = 0, U_\rho = \lambda_1, U_m - U_\rho = \lambda_2)$$

(3.5)

$$= P_\rho(|S_k| \geq \left\{c \left(\lambda_1 + \lambda_2 - \frac{\xi^2}{\rho(1 - \rho/m)}\right) + \frac{\xi^2}{\rho(1 - \rho/m)}\right\}^{1/2} \{k(1 - k/m)\}^{1/2} \text{ for some } k \neq \rho \mid S_\rho = \xi, S_m = 0, U_\rho = \lambda_1, U_m - U_\rho = \lambda_2)$$

A likelihood based, level $1 - \alpha$ confidence set $C(X)$ could then be based on the family of size $\alpha$ tests determined by (3.5), by defining

$$C(X) = \left\{ \rho : T_\rho < c \left(\alpha, \rho, S_\rho - \rho \bar{X}_m, \sum_{k=1}^{\rho} (X_k - \bar{X}_m)^2, \sum_{k=\rho+1}^{m} (X_k - \bar{X}_m)^2\right) \right\}.$$

The above procedure can be carried out by using the theorem to obtain approximate values of $c(\alpha, \rho, \xi, \lambda_1, \lambda_2)$. Assume $\rho/m \rightarrow p$, $\xi = m\xi_0$, $\lambda_1 = m\lambda_{10}$, and $\lambda_2 = m\lambda_{20}$, where $0 < p < 1$, $\xi_0$, $\lambda_{10}$, and $\lambda_{20}$ are fixed. Let $c_0 = \{c(\lambda_{10} + \lambda_{20}) + (1 - c)\xi_0 p^{-1}(1 - p)^{-1}\}$. Then the Markov property implies

$$\text{RHS (3.5)} = p_1 + p_2 - p_1 p_2,$$

where

$$p_1 = P_\rho \left(|S_k| \geq m c_0 \left\{\frac{k}{m} \left(1 - \frac{k}{m}\right)\right\}^{1/2} \text{ for some } k < \rho \mid S_\rho = \xi, U_\rho = \lambda_1\right)$$

and

$$p_2 = P_{m-\rho} \left(|S_k| \geq m c_0 \left\{\frac{k}{m} \left(1 - \frac{k}{m}\right)\right\}^{1/2} \text{ for some } k < m - \rho \mid S_{m-\rho} = \xi, U_{m-\rho} = \lambda_2\right).$$

Applying the theorem with $g(t) = c_0 \{t(1 - pt)/p\}^{1/2}$, we obtain

$$p_1 \sim \nu \left(\frac{\xi_0^2}{(1 - p)\xi_0^2 \sigma_1^2} \left(\frac{\sigma_1^2}{\lambda_{10} - \xi_0^2}\right)^{(p-3)/2} \frac{c_0}{\xi_0} \left(\frac{1 - p}{p}\right)^{1/2}\right)$$

and

$$p_2 \sim \nu \left(\frac{\xi_0^2}{(m - \rho)\xi_0^2 \sigma_2^2} \left(\frac{\sigma_2^2}{\lambda_{20} - \xi_0^2}\right)^{(m-\rho-3)/2} \frac{c_0}{\xi_0} \left(\frac{p}{1 - p}\right)^{1/2}\right),$$

where $\xi_0^2 = \xi_0^2 p(c_0^2(1 - p)^2 + \xi_0^2 p^2)^{-1}$, $\xi_1^2 = \xi_0^2 (1 - p)\{c_0^2 p^2 + \xi_0^2 (1 - p^2)^{-1}\}$, $\sigma_1^2 = \lambda_{10} - c_0^2 p^{-1} - \xi_0^2 p(1 - p)^{-1}$, and $\sigma_2^2 = \lambda_{20} - c_0^2 (1 - p)^{-1} - \xi_0^2 (1 - p)p^{-1}$ ($\sigma_1^2$ and $\sigma_2^2$ are assumed > 0).
