Adsorbed atoms on the surface of a harmonic lattice are immersed in a strong laser field. The optical Bloch equations are derived, which include the thermal relaxation and the coherent excitation of the adatom. This is accomplished by a transformation to dressed states, which diagonalizes the interaction with the laser. The single-phonon couplings are then understood as transitions between dressed states. The radiative contributions for arbitrary strong fields are obtained in the master equation, and it is shown that the coherences with respect to the dressed states decay exponentially, due to the phonon relaxation. General properties of the competing phonon-induced redistribution and optical excitation of the level populations are presented, and exemplified by an explicit elaboration of a three-level system. The results are amenable to analytical evaluation once the interaction potential is prescribed, and extensions of the approach to include multiphonon processes are straightforward.

ABSTRACT

Adsorbed atoms on the surface of a harmonic lattice are immersed in a strong laser field. The optical Bloch equations are derived, which include the thermal relaxation and the coherent excitation of the adatom. This is accomplished by a transformation to dressed states, which diagonalizes the interaction with the laser. The single-phonon couplings are then understood as transitions between dressed states. The radiative contributions for arbitrary strong fields are obtained in the master equation, and it is shown that the coherences with respect to the dressed states decay exponentially, due to the phonon relaxation. General properties of the competing phonon-induced redistribution and optical excitation of the level populations are presented, and exemplified by an explicit elaboration of a three-level system. The results are amenable to analytical evaluation once the interaction potential is prescribed, and extensions of the approach to include multiphonon processes are straightforward.

I. INTRODUCTION

Relaxation or desorption of an atom in a vibrational bond with a surface of a crystal with finite temperature is fairly described by a Pauli-type master equation and has been studied extensively.\textsuperscript{1-6} The vibrational levels of the adbond are coupled by the phonon field of the crystal, and phonon-exchange reactions of the bond with the crystal, which acts as a thermal bath, cause the relaxation or desorption. The latter process can be either a result of successive resonant single-phonon excitations up the ladder of vibrational states or, when the level separations are larger than the Debye frequency $\omega_D$, as a one-step multiphonon process. Besides the academic interest in these processes, the thermal desorption of adatoms is the major technical method to obtain clean surfaces. However, when the distances between the lower levels are large in comparison with $\omega_D$, the desorption rate might be very low, since the first excitations can only occur through multiphonon processes.

An obvious way to enhance the desorption is by irradiation of the surface with infrared laser light. The laser, with frequency $\omega_L$, is tuned in resonance with a vibrational transition. In this fashion one can efficiently populate a high-lying state, such that the transition to the continuum can be established by a resonant one-phonon process.\textsuperscript{7-11} There is obviously a competing effect, which diminishes the efficiency of this procedure. An optically-excited bond can decay to a lower state under emission of a phonon into the crystal. This can be considered as a conversion of a photon into a phonon, and the net result is an energy flux into the crystal, without desorption of the atom. On a much larger time-scale however, this process heats the crystal, and consequently the desorption is again enhanced.
The problem of irradiation of an adsorbed atom, in combination with thermal relaxation due to the coupling with the phonon reservoir, has been treated in the weak-field limit\(^{12-18}\) with a perturbative approach and for special choices of the coupling potential (harmonic, Morse).\(^{19}\) A systematic development of a concise theory for strong laser fields, which does not rely on a specific form of the potential, is apparently not available yet. In this paper, we investigate the interaction of an intense radiation field with the bounded atom. We interpret the results in terms of transition diagrams, and we identify the contributions of pure-phonon, phonon-photon exchange and one-phonon/two-photon processes to the laser-assisted redistribution of the level populations and to the decay of the coherences. Common features are illustrated by an example.

II. EQUATION OF MOTION

We consider an atom with mass \(m\), which is adsorbed on the surface of a harmonic-lattice crystal. The van der Waals forces are represented by the potential \(V\) between the adatom and its nearest surface atom, and by an effective surface-potential \(\phi\). The lateral motion of the atom will be neglected, since it couples only weakly to the phonon field, and the direction perpendicular to the surface will be denoted by \(z\). If we choose the origin of our coordinate system at the equilibrium position of the surface atom, with mass \(M\), and indicate the position of \(m\) by \(z_\perp\) and of \(M\) by \(u\), then \(V\) will only depend on the distance \(|z_\perp - u|\). Since \(|u|\) is much smaller than \(|z|\), we can expand the potential as

\[
V(|z_\perp - u|) = V_0(z) - u \cdot \frac{d}{dz} V_0(z) \ldots , \tag{2.1}
\]

where \(V_0(z)\) is defined as the interaction for \(u = 0\). We will only retain
these two terms, which implies that we neglect multiphonon processes. This
will keep the formulation concise and the interpretation transparent. It
is, however, straightforward to retain higher-order terms. The atomic part
of the interaction is abbreviated as

\[ S = \frac{d}{dz} V_0(z) , \quad (2.2) \]

and the amplitude of the phonon field for the surface atom \( M \) will be
represented by\(^\text{20}\)

\[ u = \sum_{k} \left( \frac{\hbar \omega'}{2MV_0(k)} \right)^{1/2} \left( a_{k} + a_{k}^\dagger \right) e_{ks} . \quad (2.3) \]

Here \( v \) and \( v' \) are the volumes of the crystal and unit cell, respectively,
\( e_{ks} \) is the unit polarization vector of the phonon mode \( ks \), \( a_{ks} \) and \( a_{ks}^\dagger \) are
the annihilation and creation operator for the mode \( ks \), and \( \omega(k) \) is the
dispersion relation. With this notation, the vibrational coupling of the
ad bond to the crystal is accounted for by the Hamiltonian \( H = K + V_0 + \phi + H_{ph} - u \cdot e_s S \), with \( K \) the kinetic energy of \( m \) and \( H_{ph} \) the free-field phonon
Hamiltonian,

\[ H_{ph} = \sum_{k} \hbar \omega(k) a_{k}^\dagger a_{k} \quad (2.4) \]

The pure atomic part \( K + V_0 + \phi \) of the Hamiltonian will be termed the
bare-atom Hamiltonian, since it describes the atomic bond with \( u = 0 \) and
without a laser field. Its eigenvalues \( \hbar \omega_i \) and eigenstates \( |i\rangle \) are defined by

\[ (K + V_0 + \phi)|i\rangle = \hbar \omega_i |i\rangle , \quad (2.5) \]
and explicit representations in coordinate space can easily be found for a number of potentials. A prime example here is the Morse potential, which provides a fair representation of the binding potential well, and for which analytical expressions for $\mathcal{H}_1$ and $|i\rangle$ are known. With respect to its own eigenvectors, we can write the bare-atom Hamiltonian as

$$H_b = K + V_0 + \phi = \sum_i \mathcal{H}_i P_i,$$

with

$$P_i = |i\rangle\langle i|,$$

the projector onto the eigenstate $|i\rangle$. We shall assume that for the atomic part $S$ of the interaction with the phonon field, the diagonal matrix elements $\langle i|S|i\rangle$ vanish. This is only an approximation in the presence of a laser field, since the $\langle i|S|i\rangle$-term will give rise to a small radiative contribution, but not to pure phonon transitions.

A continuous single-mode laser is tuned into resonance with a specific transition of the vibrational bond. The electric component of the electromagnetic field at the position of the bond is

$$E(t) = E_0 \text{Re}[\xi \exp(-i\omega_L t)],$$

and the coupled levels will be denoted by $|e\rangle$ and $|g\rangle$. This excited state and ground state (which is not necessarily the lowest state) are separated by $\omega_e - \omega_g > 0$, and the frequency mismatch with $\omega_L$, the detuning, will be indicated by $\Delta = \omega_L - (\omega_e - \omega_g)$. The strength of the dipole coupling is expressed in terms of the Rabi frequency

$$\Omega = \mathcal{H}^{-1} E_0 \langle e | \mathcal{H} | g \rangle.$$
which contains the dipole-moment operator $\mu$ of the vibrational bond. The interaction Hamiltonian is then $-\mu \cdot E(t)$.

The full equation of motion can now be summarized as

$$\frac{d\rho}{dt} = [H, \rho], \quad \rho^+ = \rho, \quad \text{Tr} \rho = 1,$$

(2.10)

where $\rho(t)$ is the density operator of the atomic bond and the phonon field. The Hamiltonian is given explicitly by

$$H = H_b + H_{ph} - \sum_{ks} \beta_{ks} (a_{ks} + a_{ks}^+) S_{ks} - \frac{1}{2} \hbar \Omega \{|e\rangle \langle g| e^{-i\omega_L t} + e^{i\omega_L t} |g\rangle \langle e|\},$$

(2.11)

with the free evolution of the ad bond $H_b$ and the phonon field $H_{ph}$ given by Eqs. (2.6) and (2.4), respectively. The coupling parameter with the phonon-mode $ks$ is given by

$$\beta_{ks} = \left(\frac{\hbar \nu'}{2 M v(k)}\right)^{1/2} e_{ks} \cdot e_L.$$

(2.12)

III. DRESSED STATES

The interaction between the bare states and the laser mode can be diagonalized directly. To this end we introduce the transformed density operator $\sigma(t)$ by

$$\sigma(t) = e^{-i\omega_L t P} \rho(t) e^{i\omega_L t P},$$

(3.1)

with $P$ the projector onto the ground state. This transformation eliminates the oscillatory factors in the interaction term $-\mu \cdot E(t)$, but at the expense of the appearance of a time-dependent coupling with the phonon field. The equation of motion for $\sigma(t)$ reads
\[
\begin{align*}
\text{i} \frac{\text{d} \Phi_i}{\text{d} t} &= \left[ H_d + H_{ph} \right] \Phi_i \\
&= \left\{ \begin{array}{l}
\sum_{k=1}^{n} \beta_{k} \left[ (a_{k} + a_{k}^{\dagger}) q(t), \Phi_i \right], \\
\sum_{k=1}^{n} \beta_{k} \left[ (a_{k}^{\dagger} + a_{k}) q(t), \Phi_i \right],
\end{array} \right.
\end{align*}
\] 
\tag{3.2}

with
\[
q(t) = e^{-i \omega_{L} t \Phi_i} e^{i \omega_{L} t \Phi_i}.
\tag{3.3}
\]

The dressed-atom Hamiltonian \( H_d \) is defined as
\[
H_d = \sum_{i=e,g} \omega_i \hat{P}_i \\
+ \frac{1}{2} \hbar (\omega_{L}^{(e) g} + \omega_{e} + \omega_{g})(\hat{P}_{e} + \hat{P}_{g}) - \frac{1}{2} \hbar \Delta (\hat{P}_{e} - \hat{P}_{g}) \\
- \frac{1}{2} \hbar \Delta (|e><g| + |g><e|).
\tag{3.4}
\]

which has the interpretation of the bare atom \( H_b \) dressed with the photons of the laser field, including the interaction. The dressed-atom Hamiltonian \( H_d \) is defined as

\[
H_d = \sum_{i=e,g} \omega_i \hat{P}_i \\
+ \frac{1}{2} \hbar (\omega_{L}^{(e) g} + \omega_{e} + \omega_{g})(\hat{P}_{e} + \hat{P}_{g}) - \frac{1}{2} \hbar \Delta (\hat{P}_{e} - \hat{P}_{g}) \\
- \frac{1}{2} \hbar \Delta (|e><g| + |g><e|).
\tag{3.4}
\]

which has the interpretation of the bare atom \( H_b \) dressed with the photons of the laser field, including the interaction. The eigenvalue equations of \( H_d \) are readily derived from Eq. (3.4). We obtain

\[
H_d |\Phi_i\rangle = \phi_i |\Phi_i\rangle, \quad i = \text{bare }, \quad i = e,g
\tag{3.6}
\]

\[
H_d |\xi\rangle = \phi_\xi |\xi\rangle,
\tag{3.7}
\]

with

\[
\phi_\xi = \frac{1}{2} (\omega_{L}^{(e) g} + \omega_{e} + \omega_{g}) \xi + \frac{1}{2} \Delta
\tag{3.8}
\]
where
\[ \Omega' = \Delta(1 + \Omega^2/\Delta^2)^{1/2} \quad (3.9) \]

Hence the dressed states are identical to the bare states, provided that \( i \neq e, g \). The states \(|e>\) and \(|g>\) are coupled to form \(|+>\) and \(|->\) according to
\[
|+> = |e> \cos \theta/2 + |g> \sin \theta/2, \\
|-> = |g> \cos \theta/2 - |e> \sin \theta/2, 
\]
which is a parametrization in terms of the angle \( \theta/2 \), where \( \theta \) is defined by
\[ \theta = \arctan(\Omega/\Delta) \quad (3.12) \]

For weak driving fields (\( \Omega \to 0 \)) we have \(|+> = |e>\) and \(|-> = |g>\), but for strong fields we find \(|+> = (|g> + |e>)/\sqrt{2} \). The summation in Eq. (3.5) runs over the bare states \( i = e, g \), and over \( i = \bar{i} \), where \( \bar{i} = |i><i| \). This diagonalizes the laser interaction. The relation between the eigenvalues of \( H_b \) and \( H_d \) is illustrated in Fig. 1.

The coupling to the phonon field is now regarded as an interaction between the dressed bond and the free phonons. The time dependence of this interaction is embodied in \( q(t) \) from Eq. (3.3). With the property \( P^2_g = P_g \), we can expand the exponentials as
\[
e^{-i\omega_t P_g} = I - P_g + e^{-i\omega_t P_g}, \\
e^{i\omega_t P_g} = I + P_g + e^{i\omega_t P_g}, 
\]

which allows us to write
\[
q(t) = 5 + e^{-i\omega_t P_g} S + e^{i\omega_t P_g} S \quad (3.14)
\]

Here we used that \( <g|S|g> = 0 \), and we introduced the time-independent part.
of the interaction by

$$S = S - P_S S - SP_S .$$  \hfill (3.15)

The identification of the contributions to the interaction of the three frequencies in Eq. (3.14) will facilitate the following computations considerably.

**IV. INTERACTION PICTURE**

In contrast to the photon field, where only the laser mode is occupied, the phonon field consists of many modes $k_s$, which all contribute to the interaction. This prohibits an immediate diagonalization, so other methods have to be applied. In this section we set up the notation and write down the basic equation. To this end, we introduce the density operator in the interaction picture by

$$\tilde{\sigma}(t) = e^{\frac{i}{\hbar} (H_d + H_{ph}) t} \sigma(t) e^{-\frac{i}{\hbar} (H_d + H_{ph}) t} . \hfill (4.1)$$

When there is no coupling between the dressed system and the phonon field, we have $\tilde{\sigma}(t) = \sigma(0) = \tilde{\sigma}(0)$. The equation of motion for $\tilde{\sigma}(t)$ follows from Eq. (3.2), and we obtain

$$i\hbar \frac{d}{dt} \tilde{\sigma}(t) = [W(t), \tilde{\sigma}(t)] . \hfill (4.2)$$

The interaction Hamiltonian $W(t)$ is then

$$W(t) = - \sum_{k_s} \beta_{k_s} (a_{k_s} e^{-i\omega(k)t} + a_{k_s}^+ e^{i\omega(k)t}) \tilde{q}(t) , \hfill (4.3)$$

with the transformed atomic part given by

$$\tilde{q}(t) = e^{\frac{i}{\hbar} H_d t} q(t) e^{-\frac{i}{\hbar} H_d t} . \hfill (4.4)$$
If we expand the exponentials in the projectors on the dressed states and use the expression (3.14) for \( q(t) \), we obtain

\[
\tilde{q}(t) = \sum_{k,l} e^{i \hat{\Delta}_{kl} t} \hat{P}_k \{ S + e^{-i \omega_L t} \hat{P}_S + e^{i \omega_L t} \hat{P}_S \} \hat{P}_l ,
\]

where

\[
\hat{\Delta}_{kl} = \hat{\omega}_k - \hat{\omega}_l
\]

is the level separation between the dressed states \( |k\rangle \) and \( |l\rangle \). Besides the usual time-dependence \( \exp(i \hat{\Delta}_{kl} t) \) in the interaction picture, we now also find \( \exp(i(\hat{\Delta}_{kl} + \omega_L)t) \).

Since the system of interest is the adatom, we define the reduced density operator of the dressed atom by

\[
\sigma_0(t) = \text{Tr}_{\text{ph}} \sigma(t) ,
\]

and similarly for \( \tilde{\sigma}_0(t) \). Taking the trace over the phonon field in Eq. (4.1) yields

\[
\sigma_0(t) = e^{\frac{i}{\hbar} \hat{H}_d t} \tilde{\sigma}_0(t) e^{\frac{i}{\hbar} \hat{H}_d t} ,
\]

and therefore it is sufficient to derive an equation for \( \tilde{\sigma}_0(t) \). If we iterate the first integral of Eq. (4.2) twice, differentiate the result with respect to time, and take the trace over the phonon field, we obtain

\[
\frac{d}{dt} \tilde{\sigma}_0(t) = -\frac{i}{\hbar^2} \text{Tr}_{\text{ph}} \int_0^t \text{d}t' \{ \hat{W}(t) , i \hat{\omega}(t') , \tilde{\sigma}(t') \} .
\]

The right-hand side of this equation accounts for the phonon interaction in the evolution of \( \sigma_0(t) \).
V. PHONON RESERVOIR

The phonon field will be considered as a large reservoir,\textsuperscript{29-31} or heat bath, with a short recovery time. Then the integral in Eq. (4.9) can be evaluated by standard techniques,\textsuperscript{29-33} so here we merely state the result. Care should be exercised, however, since the atomic part of the interaction, $\tilde{q}(t)$, contains three frequencies for a single $k\ell$ matrix element. This gives rise to a number of cross terms, which do not appear without a laser field.

The average number of phonons in mode $\omega$ for the crystal in thermal equilibrium at temperature $T$ is

$$n(\omega) = [\exp(\hbar\omega/k_B T) - 1]^{-1} . \quad (5.1)$$

We extend the definition of $n(\omega)$ to negative values of $\omega$, which enables us to write

$$n(\omega) + 1 = -n(-\omega) . \quad (5.2)$$

This will simplify the notation considerably. Next we introduce another function of $\omega$ by

$$f(\omega) = \zeta \frac{1}{\omega} \left| \frac{dk(|\omega|)}{d|\omega|} \right| k^2(|\omega|) [n(\omega) + 1] , \quad (5.3)$$

with

$$\zeta = \frac{v}{2\pi\hbar M} , \quad (5.4)$$

in terms of the dispersion relation $k = k(\omega)$, which is the inverse of $\omega = \omega(k)$. This $f(\omega)$ enters because of the summation over all modes $k\ell$ of the reservoir.

After these preliminary definitions, we can evaluate the integral in Eq. (4.9). We obtain the simple result
\[
\frac{d}{dt} \tilde{\sigma}_0(t) = -\frac{1}{2} \sum_{k\ell} |S_{k\ell}|^2 (\{P_{k} \tilde{\sigma}_0(t) + \tilde{\sigma}_0(t) P_{k} - 2 \tilde{P}_{k} \langle k | \tilde{\sigma}_0(t) | k \rangle \})
\]
\[
-\frac{1}{2} \sum_{\pm\ell} g_{\pm} |S_{g\ell}|^2 f(\tilde{\alpha}_{\pm\ell} - \omega_L)
\times \{P_{\pm} \tilde{\sigma}_0(t) + \tilde{\sigma}_0(t) P_{\pm} - 2 \tilde{P}_{\pm} \langle \pm | \tilde{\sigma}_0(t) | \pm \rangle \}
\]
\[
-\frac{1}{2} \sum_{k\ell} g_{\pm} |S_{g\ell}|^2 f(\tilde{\alpha}_{k\ell} + \omega_L)
\times \{P_{k} \tilde{\sigma}_0(t) + \tilde{\sigma}_0(t) P_{k} - 2 \tilde{P}_{k} \langle k | \tilde{\sigma}_0(t) | k \rangle \}.
\]
- \sum_{\pm\ell} g_{\pm} |S_{eg}|^2 (f(\omega_L) + f(-\omega_L)) \sum_{\pm\ell} \tilde{P}_{\pm} \tilde{\sigma}_0(t) \tilde{P}_{\pm} \quad \text{(5.5)}
\]

The first term comes from the time-independent part \(S\) of the interaction, and is proportional to \(|S_{k\ell}|^2 = |\langle k | S | \ell \rangle|^2\). Here the summation runs over all dressed states \(k, \ell\). The second and the third terms only connect the dressed states \(\pm\ell\) with all other states. In the first term, the overall factor contains \(f(\tilde{\alpha}_{k\ell})\), which depends only on the level distance \(\tilde{\omega}_k - \tilde{\omega}_\ell\), but in the other two terms, this frequency is shifted by the optical frequency \(\omega_L\). Furthermore, they involve the geometrical factors
\[
g_{\pm} = \langle \pm | P_{g} | \pm \rangle \quad \text{(5.6)}
\]
e.g., the matrix elements of the projector on the ground state with respect to the dressed states. This factor is only non-vanishing for the states \(|+\rangle\) and \(|-\rangle\), which explains the limited summations in the last two terms. For later purposes we note that \(g_{\pm}\) can be expressed in terms of the optical parameters \(\Omega'\) and \(\Delta\) according to
\[
g_{\pm} = \frac{\Omega' \mp \Delta}{2\Omega'} \quad \text{(5.7)}
\]
as can be found from the definitions (3.10) and (3.11) of the dressed states.
Notice that the operator equation (5.5) for $\tilde{O}_0(t)$ involves only well-defined quantities. The projectors inside the curly brackets select a specific matrix element of $\tilde{O}_0(t)$ with respect to the dressed states, and the prefactors contain $f(\omega)$, a given function of $\omega$ and the temperature, and the matrix elements of $S = dV_0/dz$. Besides that, the optical parameters $g_2$ appear, which are known functions of $\Omega^2$ and the detuning $\Delta$. In view of Eq. (2.9), the parameter $\Omega^2$ is proportional to the laser intensity and to the square of the transition-dipole moment. It is this combination that determines whether a laser field can be treated as a weak field (perturbation), or not. We address this item in more detail in Section VII. The temperature enters parametrically through $f(\omega)$ from Eq. (5.3). If the laser heating of the crystal is considerable, the temperature will depend on time, and hence an additional macroscopic heat-transport equation has to be supplied. However, if the direct heating is dominant, the details of the atomic evolution and the radiative excitation of the adbond have no importance. Therefore, we assume an "adiabatic following" with temperature in this paper.

VI. THE BLOCH EQUATIONS

For a given transition $|k\rangle \to |\ell\rangle$ there might be a contribution from more than one term in Eq. (5.5) if $k = \pm$ or $\ell = \pm$. In order to distinguish between the various contributions in every transition, we rearrange the terms. Furthermore, we will express all matrix elements of $S$ and $\tilde{S}$ in terms of bare-state matrix elements. This implies that the optical parameters will appear in the overall factors, and hence the effect of the laser is tracked down explicitly in every transition.

From the definition of $\tilde{S}$, Eq. (3.15), it follows immediately that

$$<k|\tilde{S}|\ell> = <k|S|\ell>, \text{ if } k \neq \pm, \ell \neq \pm,$$  

(6.1)
so that for states $|k\rangle, |\ell\rangle$, which are not directly coupled by the laser, we can replace $S$ by $S$. If one of these states equals $|+\rangle$ or $|-\rangle$, we obtain

$$|S_{\pm k}|^2 = g_{\pm} |S_{ek}|^2 , \text{ if } k \neq \pm ,$$

(6.2)

and again $g_{-}$ accounts for the optical effects. We note that these matrix elements connect the excited state $|e\rangle$ with $|k\rangle$. Finally, we find

$$\langle k | S | \ell \rangle = 0$$

(6.3)

if both $|k\rangle$ and $|\ell\rangle$ are one of the states $|+\rangle$ or $|-\rangle$. For the matrix elements of $S$ itself, as they appear in the second and the third terms of Eq. (5.5), we find

$$|S_{g\pm}|^2 = g_{+} |S_{eg}|^2 .$$

(6.4)

A transition $|k\rangle \rightarrow |\ell\rangle$ might gain contributions from more than one term in Eq. (5.5), but for the time evolution of $\tilde{S}_0(t)$ these terms add up. Hence, we can define the effective rate constants $a_{k\ell}$ for every specific transition $|k\rangle \rightarrow |\ell\rangle$. The radiationless coupling between two bare states is governed by

$$a_{k\ell} = f(\hat{a}_{k\ell}) |S_{k\ell}|^2 , \quad k \neq \pm , \quad \ell \neq \pm .$$

(6.5)

For $k = \ell$ this rate constant is zero, because we assumed $S_{kk} = 0$. If one of the states equals $|+\rangle$ or $|-\rangle$, we obtain

$$a_{+\ell} = g_{-} f(\hat{a}_{+\ell}) |S_{e\ell}|^2 + g_{+} f(\hat{a}_{+\ell} - \omega_L) |S_{eg}|^2 ,$$

(6.6)

$$a_{k+} = g_{-} f(\hat{a}_{k+}) |S_{ek}|^2 + g_{+} f(\hat{a}_{k+} + \omega_L) |S_{eg}|^2 ,$$

(6.7)
for $t = i$, $k = i$. The transition rates between the two $|i\rangle$ doublets are determined by

\begin{align*}
a_{++} &= a_{--} = g_{+} g_{-} [f(-\omega_{L}) + f(\omega_{L})] |S_{eg}|^2, \\
a_{+-} &= [g_{+}^2 f(-\omega' - \omega_{L}) + g_{-}^2 f(-\omega' + \omega_{L})] |S_{eg}|^2, \\
a_{-+} &= [g_{-}^2 f(\omega' - \omega_{L}) + g_{+}^2 f(\omega' + \omega_{L})] |S_{eg}|^2.
\end{align*}

We note that $a_{kk} = 0$ if $k = +$ or $k = -$.

With these identifications of the various contributions, Eq. (5.5) can be summarized as

\begin{align*}
\frac{d}{dt} \tilde{\sigma}(t) &= -\frac{1}{2} \sum_{k,l} a_{kl} \left[ \rho_{k} \tilde{\sigma}(t) + \tilde{\sigma}(t) \rho_{k} - 2 \rho_{k} \langle k | \tilde{\sigma}(t) | k \rangle \right] \\
&\quad - a_{++} \sum_{l} \rho_{l} \tilde{\sigma}(t) \rho_{l}^{-}
\end{align*}

(6.11)

for the atomic density operator in the interaction picture. Transforming back with Eq. (4.8) then yields the optical Bloch equations for this system. We find

\begin{align*}
\frac{d}{dt} \sigma(t) &= [H, \sigma(t)] - i \hbar \Gamma \sigma(t), \quad \sigma(t)^\dagger = \sigma(t), \quad \text{Tr} \sigma(t) = 1,
\end{align*}

(6.12)

where the Liouville operator $\Gamma$ is defined by its action on an arbitrary operator $\rho$ according to

\begin{align*}
\Gamma \rho &= \frac{1}{2} \sum_{k,l} a_{kl} (\rho_{k} \rho + \rho_{k} \rho^{-} - 2 \rho_{k} \langle k | \rho | k \rangle) + a_{++} \sum_{l} \rho_{l} \rho \rho_{l}^{-}.
\end{align*}

(6.13)

Here the summation runs over all dressed states. This $\Gamma$ represents the relaxation of the adbond due to single-phonon transitions, and it incorporates the combined phonon-photon processes, as will be explained in the next section.
VII. DIAGRAMS

The structure of the relaxation operator $\Gamma$ is quite transparent. Every $k\ell$-combination assumes the form $\frac{1}{2}(\hat{p}_k\sigma_0 + \sigma_0\hat{p}_k - 2\hat{p}_k\langle k|\sigma_0|k\rangle)$ times a constant $a_{k\ell}$, and in the next section it will become clear that this action on $\sigma_0$ corresponds to a transition $|k\rangle \rightarrow |\ell\rangle$ at a rate of $a_{k\ell}$ times the population of level $|k\rangle$. Therefore, $a_{k\ell}$ is termed the rate constant or the inverse lifetime of the transition. On the other hand, we actually know which term corresponds to which transition, because every term reflects a single-phonon excitation or decay. The particular transition can then be inferred from the definition (6.5)-(6.10) of the rate constants, since any appearance of a factor $f(\omega)$ displays the occurrence of a single-phonon transition with phonon frequency $|\omega|$. Here a positive argument $\omega$ pertains to a downward transition, and $\omega < 0$ corresponds to an excitation. Both $f(\omega)$ and $f(-\omega)$ appear for every transition, and the inverse lifetime for a decay is always larger than for an excitation. For zero temperature we have $n(\omega) = 0$, so that the upward transitions disappear identically, and we are left with a pure decaying system. The occurring transitions between dressed states with their optical part of the rate constants are pictorially represented in Fig. 2, and in Fig. 3 we plot the explicit dependence on the optical parameters $\Omega$ and $\Delta$.

At this stage it is elucidating to consider the limit of a weak driving field. The laser intensity is proportional to $\Omega^2$. For $\Omega^2 = 0$ we find from Eq. (5.7)

\[ g_- = 1 \quad g_+ = \frac{\Omega^2}{4\Delta^2} \quad (7.1) \]

for the parameters which determine the transition rates. Furthermore, the dressed states of Fig. 1 approach the bare states, since $\Omega' = \Delta$. If we
inspect the transitions of Fig. 2, we can now also consider them as bare-
state transitions, where every appearance of a factor $g_+^+$ corresponds to one
photon. This is illustrated in Fig. 4 for single-phonon excitations. We
obtain three diagrams without photons, and five radiation-assisted
transitions, which disappear for a zero intensity.

VIII. MATRIX ELEMENTS

Equation (6.12) contains all information about the state of the bounded
atom, including its interaction with the phonon field and the radiation. It
is a condensed operator equation, but in order to solve it, we have to
rewrite it in matrix form. This is easily accomplished if we use the
explicit form (6.13) of the damping operator. The equation of motion for
the $k\ell$-th matrix element of $\sigma_0(t)$ attains the form

$$
\frac{d}{dt} <k|\sigma_0(t)|\ell> = -i(\hat{\omega}_k - \hat{\omega}_\ell) <k|\sigma_0(t)|\ell> 
- \frac{1}{2} <k|\sigma_0(t)|\ell> \sum_n (a_{kn}^+ + a_{kn}) 
+ \delta_{k\ell} \sum_n a_{nk} <n|\sigma_0(t)|n> 
- a_{+-} <k|\sigma_0(t)|\ell> \sum_{\ell=+} \delta_{k\ell} \delta_{\ell+} 
$$

(8.1)

Now we can distinguish two cases. First, for $k = \ell$ and $k$ and $\ell$ not both
equal to + or - we find

$$
\frac{d}{dt} <k|\sigma_0(t)|\ell> = (-i(\hat{\omega}_k - \hat{\omega}_\ell) - \frac{1}{2}(A_k^+ + A_\ell)) <k|\sigma_0(t)|\ell> 
$$

(8.2)

where we introduced the abbreviation

$$
A_k = \sum_n a_{kn} 
$$

(8.3)

Equation (8.2) is an equation for a single coherence of $\sigma_0(t)$, and we note
that its time evolution decouples from the evolution of the other matrix
elements. The solution is
\begin{equation}
<k|\sigma_0(t)|t> = e^{-i(\hat{\omega}_k - \hat{\omega}_\ell)t} \frac{1}{2} (A_k + A_\ell)t \frac{1}{e^{\frac{1}{2}(A_k + A_\ell)t}} <k|\sigma_0(0)|t>
\tag{8.4}
\end{equation}
for a given initial state \(\sigma_0(0)\). For \(t \gg (A_k + A_\ell)^{-1}\) we find \(<k|\sigma_0(t)|t> = 0\) for any initial state \(\sigma_0(0)\). This justifies the random-phase approximation with respect to dressed states and in the long-time limit.

Since the coherences between dressed states vanish, they do not disappear with respect to the bare states, as is commonly assumed in a random-phase approximation.

For \(k = \ell\) we obtain the master equation
\begin{equation}
\frac{d}{dt} n_k(t) = -A_k n_k(t) + \sum_\ell a_{k\ell} n_\ell(t) \tag{8.5}
\end{equation}
where we have denoted the population of the \(k\)-th level by
\begin{equation}
n_k(t) = <k|\sigma_0(t)|k> \tag{8.6}
\end{equation}
Equation (8.5) involves the populations of all levels, but it does not couple with the coherences. This shows that a master-equation approach is only correct with respect to the dressed states, since a transformation of Eq. (8.5) to bare states involves coherences. In the bare-state basis we have to include all matrix elements simultaneously, which is a cumbersome procedure.

Equation (8.5) for the populations is a simple set of linear first-order differential equations with time-independent coefficients, and it can be solved easily for any configuration of states \(|k\rangle\). The set (8.5) has to be accompanied by the normalization
\begin{equation}
\sum_k n_k(t) = \text{Tr}\sigma_0(t) = 1 \tag{8.7}
\end{equation}
The structure of Eq. (8.5) is obvious. The population of $|k\rangle$ decays exponentially with an inverse lifetime $A_k$ due to decay/excitation to all other levels, and it is modified by the gain-term $a_k n_k(t)$ from every other level $|l\rangle$. This shows that a $|k\rangle \rightarrow |l\rangle$ transition occurs at a rate $a_k n_k(t)$, as already mentioned in Section VII. Furthermore, level $|k\rangle$ decays with a total rate $A_k n_k(t)$, and the coherence between $|k\rangle$ and $|l\rangle$ decays with $\frac{1}{2}(A_k + A_l)$. This also clarifies, at that stage, the arbitrary factor $\frac{1}{2}$, which was separated from the overall factors in Eq. (5.5).

IX. DECAY OF DRESSED STATES

The rate constants $a_{kl}$ for every transition $|k\rangle \rightarrow |l\rangle$ between dressed states are defined in Eqs. (6.5)-(6.10). They are also defined for $k$ or $l$ equal to $e$ or $g$ in Eq. (6.5). We now make a slight approximation in the level-distance dependence of the constants by assuming that $f(\omega)$ does not vary significantly over one $|l\rangle$-doublet. This is exact for weak fields and perfect resonance. Then we can express the rate constants entirely in the bare-atom transition constants (6.5) and the laser parameters $g_\pm$. We obtain

\begin{align}
a_{\pm} & = g_- a_{\pm} + g_+ a_{\mp} , \quad t \neq t , \\
a_{kl} & = g_+ a_{kl} + g_- a_{lk} , \quad k \neq l , \\
a_{++} & = a_{--} = g_+ g_- (a_{eg} + a_{ge}) , \\
a_{+-} & = g_+ a_{ge} + g_- a_{eg} , \\
a_{-+} & = g_- a_{ge} + g_+ a_{eg} .
\end{align}

\hspace{1cm} (9.1)
\hspace{1cm} (9.2)
\hspace{1cm} (9.3)
\hspace{1cm} (9.4)
\hspace{1cm} (9.5)

In analogy with the definition (8.3) for the total decay constant $A_k$ of a dressed state, we now define
\[ A_k = \sum_{n = \text{bare}} a_{kn}, \quad k = \text{bare} \quad (9.6) \]

which would be the relaxation constant for the bare state \( |k> \) if the laser field were not present. Now it can be proven immediately from Eqs. (9.1)-(9.5) that the definition (9.6) is identical to

\[ A_k = \sum_{n = \text{dressed}} a_{kn}, \quad k = \text{bare} \quad (9.7) \]

provided that we define \( a_g^\pm \) and \( a_e^\pm \) as in Eq. (9.2). This remarkable result states that the decay constant for the bare state \( |k> \), including \( k = e \) and \( k = g \), is unaffected by the presence of the laser.

The decay of the dressed states \( |\pm> \) can now easily be expressed in terms of the rate constants of the bare levels \( |e> \) and \( |g> \). The result is

\[ A_\pm = g_+ A_e^\pm + g_- A_g^\pm \quad (9.8) \]

Here \( A_e \) and \( A_g \) are defined by Eq. (9.6), and they are independent of optical parameters. The \( g_\pm \) factors enter into Eq. (9.8), so that the decay of the dressed states does depend on \( \Omega \) and \( \Delta \). From \( g_+ + g_- = 1 \) it follows that

\[ A_+ + A_- = A_e + A_g \quad (9.9) \]

which is not so obvious, since \( A_+ + A_- \) or \( A_e + A_g \) have no direct physical interpretation. Recall that the loss rate from the doublet \( |\pm> \) equals

\[ A_+ n_+(t) + A_- n_-(t). \]

X. STEADY STATE

The master equation (8.5) can be solved immediately for any initial set of populations \( n_k(0) \). The transient behavior of the solution is however trivial, since we have a pure exponentially-decaying system. Furthermore,
it is experimentally not feasible to prepare the system in a well-defined initial state. Due to the relaxation however, every $\sigma_0(0)$ will evolve to a steady-state $\bar{\sigma}$, defined as

$$\bar{\sigma} = \lim_{t \to \infty} \sigma_0(t) ,$$  

(10.1)

which is not necessarily unique. Similarly, we denote $n_k(\infty)$ by $\bar{n}_k$. In this limit, the master equation reduces to

$$A_k \bar{n}_k = \sum_{\ell = \text{dressed}} a_{\ell k} \bar{n}_\ell ,$$  

(10.2)

or equivalently

$$\sum_{\ell = \text{dressed}} (\bar{n}_\ell a_{\ell k} - \bar{n}_k a_{k \ell}) = 0 .$$  

(10.3)

We will now derive some salient features of the steady-state solution. We recall that the coherences vanish with respect to the dressed states, so that $\bar{\sigma}$ is given by

$$\bar{\sigma} = \sum_{k = \text{dressed}} \bar{n}_k \bar{P}_k ,$$  

(10.4)

in terms of the solution of Eq. (10.3) and the projectors $\bar{P}_k$ on the dressed states. With the definition of the $|\ell>\text{ states in Eqs. (3.10) and (3.11), we can transform the density matrix $\bar{\sigma}$ to the bare-state representation, which yields

$$\bar{\sigma} = \sum_{k = \text{bare}} \bar{n}_k \bar{P}_k + \frac{\Omega}{2\bar{n}} \left( \bar{n}_+ - \bar{n}_- \right) (|e><g| + |g><e|) .$$  

(10.5)

Here $\bar{n}_k$ is the same as $\bar{n}_k$ in Eq. (10.4) for $k = e, g$, and the relation between the populations $\bar{n}_e, \bar{n}_g$ and $\bar{n}_\perp$ is explicitly
\[ \bar{n}_e = g_+ \bar{n}_+ + g_+ \bar{n}_- \quad \text{(10.6)} \]

\[ \bar{n}_g = g_+ \bar{n}_+ + g_- \bar{n}_- \quad \text{(10.7)} \]

Equation (10.5) shows that a non-vanishing coherence \( <e|\bar{\sigma}|g> \) appears in the bare-state representation. With the aid of Eqs. (10.6) and (10.7), we find the relation

\[ \bar{n}_+ - \bar{n}_- = \frac{\bar{n}_g - \bar{n}_e}{g_+ - g_-} \quad \text{(10.8)} \]

and with the expression (5.7) for \( g_\pm \), we obtain for the coherence

\[ <e|\bar{\sigma}|g> = \frac{\Omega}{2\Delta} (\bar{n}_e - \bar{n}_g) \quad \text{(10.9)} \]

In the absence of a laser we have \( \Omega = 0 \), and \( <e|\bar{\sigma}|g> \) vanishes.

Relations (10.6) and (10.7) can be inverted to express \( \bar{n}_\pm \) in terms of \( \bar{n}_e \) and \( \bar{n}_g \). If we subsequently use Eq. (9.8) for the relation between the rate constants, we find

\[ A_+ \bar{n}_+ + A_- \bar{n}_- = A_\bar{n}_e + A_\bar{n}_g \quad \text{(10.10)} \]

This identity expresses that the total loss rate of \( |t> \) equals the sum of the loss rates of \( |e> \) and \( |g> \), as could be expected.

An advantage of the application of dressed states is that the master equation (10.3) has a simple form. With the relations of Section IX, we can transform Eq. (10.3) to its bare-state equivalent. We find

\[ \left\{ \begin{array}{l}
\bar{n}_{t=\text{bare}} \\
\bar{n}_{t} = \\
\sum_{k \neq k, k \neq e, g} A_k \bar{n}_k, \quad k = e, g, \\
\end{array} \right.
\]

\[ = \left\{ \begin{array}{l}
A_{g} \bar{n}_g + \frac{\Omega^2}{4\Delta^2} (A_e + A_g)(\bar{n}_e - \bar{n}_g), \quad k = g, \\
A_{e} \bar{n}_e + \frac{\Omega^2}{4\Delta^2} (A_e + A_g)(\bar{n}_e - \bar{n}_g), \quad k = e, \\
\end{array} \right. \quad \text{(10.11)} \]
where all quantities pertain to bare-state properties. This result is remarkably simple also. The laser only modifies the master equation for $k = g$ and $k = e$ in the form of an additional term, and the optical parameters only appear in the combination $\Omega^2/\hbar^2$. The set (10.11) couples, however, between all $k$-values, and therefore the extra terms affect all populations $\bar{n}_k$. We notice that the right-hand side of the master equation for $k = e$ and $k = g$ contains the same radiative contribution. If we add the two equations, we are left with

$$\sum_k \bar{n}_k (a_{kg} + a_{ke}) = A_g \bar{n}_g + A_e \bar{n}_e ,$$

(10.12)

and the laser has disappeared completely in this combination.

Let us now consider a specific situation. Suppose that the ground state $|g\rangle$ is the lowest state and that its separation from every other level is larger than the Debye frequency. Then the single-phonon transition rates from and to $|g\rangle$ can be neglected in comparison with the radiative coupling to $|e\rangle$. From Eq. (10.11) for $k = g$, it then follows that

$$\bar{n}_g = \bar{n}_e ,$$

(10.13)

and the master equation reduces to

$$\sum_k \bar{n}_k a_{k\bar{e}} = A_k \bar{n}_k ,$$

(10.14)

t = bare

for every bare state $|k\rangle$. This is, however, the Master equation in the absence of the laser, and it might seem that the laser has no effect at all. Such is not the case. The master equation always provides one superfluous equation, which allows us to impose the normalization (8.7) on the solution. Now we have the restriction $\bar{n}_e = \bar{n}_g$, so Eq. (8.7) should be replaced by the constraint
2\overline{n}_e + \sum_{k = e, g} \overline{n}_k = 1 \quad \text{(10.15)}

This proves that for this specific configuration the distribution of population over the states is purely thermal for \( k \neq g \), e.g., independent of the laser intensity. The normalization (10.15) indicates that we can ignore the ground state completely, provided that we take into account that there is a population equal to \( \overline{n}_e \) missing. The desorption rate is determined by the populations of the upper levels, which implies that the presence of the laser enhances the desorption. Indeed, population which would be trapped in the ground state is now continuously pumped upwards to the desorptive states.

XI. SIMPLE THREE-LEVEL EXAMPLE

In order to demonstrate the applicability of our approach, we elaborate an example. Suppose that we have, beside the levels \( |e\rangle \) and \( |g\rangle \), one other level \( |\eta\rangle \). Three independent rate equations are then

\[ \overline{n}_e a_{eg} + \overline{n}_g a_{g\eta} = A \overline{n}_e g + \frac{\overline{n}_e^2}{4\Delta^2} (A_e + A_g)(\overline{n}_e - \overline{n}_g) \quad \text{(11.1)} \]

\[ \overline{n}_e A_{eg} + \overline{n}_g A_{g\eta} = A \overline{n}_e \eta \quad \text{(11.2)} \]

\[ \overline{n}_g + \overline{n}_e + \overline{n}_\eta = 1 \quad \text{(11.3)} \]

which are Eq. (10.11) for \( k = g \), \( k = \eta \) and the normalization. If we add Eq. (11.1) to Eq. (10.11) for \( k = e \), we obtain Eq. (11.2). The solution of the set (11.1)-(11.3) is easily found. For \( \overline{n}_\eta \) we obtain

\[ \overline{n}_\eta = \left( a_{eg} a_{g\eta} + a_{ge} a_{e\eta} + a_{g\eta} a_{e\eta} + \frac{\overline{n}_e^2}{4\Delta^2} (A_e + A_g)(a_{e\eta} + a_{g\eta}) \right) \]

\[ \times \left( a_{eg} \eta + a_{e\eta} g + a_{ne} g + a_{e\eta} e + a_{g\eta} g + a_{ge} e \right) \]
\begin{align}
+a_{\eta g} a_{ge} + \frac{\Omega^2}{4\Delta^2} (A_e + A_g) (a_{en} + a_{\eta n} + 2A_{\eta})^{-1} ,
\end{align}

(11.4)

and similar expressions hold for $n_e$ and $\bar{n}_g$. This result displays explicitly the dependence on the optical parameter $\Omega^2/\Delta^2$ and the laser-independent inverse lifetimes.

If we now set $\omega - \omega > \omega_D$ and $\omega - \omega > \omega_D$, Eq. (11.4) reduces to

$$
\bar{n}_\eta = \frac{a_{en}}{a_{en} + 2a_{\eta e}}
$$

(11.5)

and the populations of $\bar{n}_e$ and $\bar{n}_g$ are

$$
\bar{n}_e = \bar{n}_g = \frac{a_{\eta e}}{a_{en} + 2a_{\eta e}}
$$

(11.6)

This shows that in this limit the dependence on the laser intensity indeed vanishes, as stated in general in the previous section. Without a laser, the stationary state for this limit becomes

$$
\bar{n}_\eta = \bar{n}_e = 0 , \quad \bar{n}_g = 1
$$

(11.7)

Hence the laser sustains a finite population of the states $|e\rangle$ and $|\eta\rangle$, which have a finite desorption rate.

XII. CONCLUSIONS

We have studied the interaction of a physisorbed atom with strong coherent radiation. The mechanisms of spontaneous phonon transitions of the vibrational atomic bond and the photon absorptions and stimulated emissions all give rise to a redistribution of the level populations. The thermal relaxation, due to phonon-exchange reactions, drives the system towards equilibrium with the phonon reservoir, but the irradiance tends to maintain a temperature gradient between the adsorb and the phonon field. This can be
understood from the underlying photon-phonon exchange reactions via the adbond, as pictorially displayed in Fig. 4. Since the absorption rate does not necessarily equal the rate of stimulated emission, a net photon absorption rate will remain. For strong fields this simple picture does not apply anymore, and we have to consider multiphoton processes as well. This was accomplished by the introduction of the dressed states, which are schematically presented in Fig. 1. The Hamiltonian of the atom plus the laser, including the interaction, is diagonal with respect to these dressed states. The interaction with the phonon field was restricted to single-phonon transitions, which were assumed to be dominant. For situations where this is not the case, higher-order processes can easily be included. In practical situations only two, not necessarily adjacent, levels will be coupled resonantly by the laser. The generic idea is to drive a \( |g\rangle \rightarrow |e\rangle \) transition, with \( |g\rangle \) as one of the low-lying states and \( |e\rangle \) as close as possible to the continuum. This configuration prohibits resonant coupling of other transitions and gives a maximum enhancement of the desorption. Besides that, the optical frequency will be larger than \( \omega_D \), and consequently the direct crystal-heating is absent. Hence, our two-level and adiabatic approach can be regarded as quite general.

The dressed states appear to be a convenient basis set for the derivation of the optical Bloch equations for this configuration. The master equation was obtained by taking the matrix elements of the full operator equation, and it was shown that the populations obey the Pauli equation. The coefficients involve, however, the optical parameters \( \Omega \) and \( \Delta \), and hence the lifetimes of the transitions depend on the properties of the driving field. Furthermore, it was shown that the coherences with respect to the dressed states decay exponentially to zero. The master
equation in the bare-state representation and in the steady state was obtained by applying the relation between dressed states and bare states. We found that the master equation greatly resembles the radiationless equations, and that the presence of the laser could be incorporated entirely by the addition of a few terms.

The general theory was exemplified by the simple case of a three-level system. We achieved the explicit steady-state solution for the bare-state populations, and it was pointed out that the system can be desorptive due to the continuous optical excitation, whereas the bond would be completely in its lower, non-desorbing state in the absence of the irradiance.

Figure Captions

Fig. 1. The energy levels of the bare system plus the free laser field are represented by the diagram on the left-hand side. The detuning $\Delta$ is taken positive. The number of photons in the laser mode is indicated by $n$. If the dipole coupling $-\mu E$ is included, a new diagonalization yields the dressed energy-level system on the right-hand side. The level separations $\Delta$ and $\omega_L$ in the bare system now become $\Omega'$ and $\omega_L'$, where $\Omega'$ is always larger than $\Delta$ due to $\Omega^2 > 0$. This is the ac-Stark shift. The state $|k\rangle$, which is not coupled to another level by the laser, remains unaltered. In general, we suppress the quantum number $n$ and represent the dressed atom as an infinite ladder of states $|i\rangle$, which is the famous Jaynes-Cummings model for the interaction of a two-level system with a strong radiation field.

Fig. 2. Illustration of the single-phonon transitions, whenever a $|+\rangle$ or $|-\rangle$ state is involved. The parameters near the arrows are the optical parts of the prefactors as they occur in the transition rates. Without a driving laser, the $g_+$ vanishes, and hence only the double-arrowed transitions survive. For weak incident fields, the single arrows appear, and only for sufficiently strong fields will the dashed transition $|+\rangle \rightarrow |-\rangle$ be present. We note that there are no transitions in a single doublet. Furthermore, the corresponding downward transitions have the same optical factor but a different $f(\omega)$, e.g., a different temperature dependence. Besides these transitions, we have single-phonon processes between any two bare states $|k\rangle$ and $|i\rangle$, which are obviously independent of the laser parameters.

Fig. 3. The optical factors in the transition rates as a function of $\Omega^2/\Delta^2$. For strong fields or small detunings, both $g_+$ and $g_-$ tend to their asymptotic value of 1/2, which is the upper dotted line, and $g_+^2$, $g_-^2$ and
$g_+g_-$ will approach $1/4$ in this limit. For weak fields or large detunings, we have $g_- = g_{-}^2 = 1$ and $g_+ = g_{+}^2 = g_+g_- = 0$. For increasing field strengths, the $g_-^2$ transition will diminish very strongly, in favor of the other three processes between the $|i\rangle$ doublets.

Fig. 4. Single-phonon excitations in the low-intensity limit. For $\Omega^2$ small, we can consider the transitions between the dressed states, as given in Fig. 2, as photon-assisted transitions between the bare states. The diagrams in this picture have the same order as the transitions in Fig. 2. Here every diagram connects two of the three bare states $|k\rangle$, $|e\rangle$ or $|g\rangle$, since we cannot populate a virtual level (dotted lines). A straight line indicates a phonon, and a wiggly arrow is a photon with frequency $\omega_L$. The three double-arrow transitions in Fig. 2 are the three radiationless transitions, so they persist even if we switch off the laser field. The single arrows from Fig. 2. appear to correspond to one-photon transitions in this diagram, so they arise already for low intensities. The diagram on the right-hand side is a two-photon process, which consequently appears for relatively strong fields only. It is the dashed $g_+^2$ transition form $|+\rangle$ to $|-\rangle$ in Fig. 2. The phonon-decay processes correspond to the inverse diagrams (reverse the direction of all arrows). In this figure we only draw the phonon excitations, which correspond to the absorption of a phonon by the adibond from the crystal. The third diagram represents the absorption of a photon from the laser field, but all other diagrams give rise to stimulated emissions of photons.
\[ |n, k\rangle \quad |n, g\rangle \quad |n-1, e\rangle \quad |n-1, +\rangle \]

\[ |n+1, g\rangle \quad |n, e\rangle \quad |n, +\rangle \quad |n, -\rangle \]

\[ \Delta \quad \omega_L \quad \Omega' \]

ABSTRACTS DISTRIBUTION LIST, 056/625/629

Dr. F. Carter
Code 6132
Naval Research Laboratory
Washington, D.C. 20375

Dr. Richard Colton
Code 6112
Naval Research Laboratory
Washington, D.C. 20375

Dr. Dan Pierce
National Bureau of Standards
Optical Physics Division
Washington, D.C. 20234

Dr. R. Stanley Williams
Department of Chemistry
University of California
Los Angeles, California 90024

Dr. R. P. Messmer
Materials Characterization Lab.
General Electric Company
Schenectady, New York 22217

Dr. Robert Gomer
Department of Chemistry
James Franck Institute
5640 Ellis Avenue
Chicago, Illinois 60637

Dr. Ronald Lee
R301
Naval Surface Weapons Center
White Oak
Silver Spring, Maryland 20910

Dr. Paul Schoen
Code 5570
Naval Research Laboratory
Washington, D.C. 20375

Dr. John T. Yates
Department of Chemistry
University of Pittsburgh
Pittsburgh, Pennsylvania 15260

Dr. Richard Greene
Code 5230
Naval Research Laboratory
Washington, D.C. 20375

Dr. L. Kesmodel
Department of Physics
Indiana University
Bloomington, Indiana 47403

Dr. K. C. Janda
California Institute of Technology
Division of Chemistry and Chemical Engineering
Pasadena, California 91125

Dr. E. A. Irene
Department of Chemistry
University of North Carolina
Chapel Hill, North Carolina 27514

Dr. Adam Heller
Bell Laboratories
Murray Hill, New Jersey 07974

Dr. Martin Fleischmann
Department of Chemistry
Southampton University
Southampton S09 5NH
Hampshire, England

Dr. John W. Wilkins
Cornell University
Laboratory of Atomic and Solid State Physics
Ithaca, New York 14853

Dr. Richard Smardzewski
Code 6130
Naval Research Laboratory
Washington, D.C. 20375

Dr. H. Tachikawa
Chemistry Department
Jackson State University
Jackson, Mississippi 39217
ABSTRACTS DISTRIBUTION LIST, 056/625/629

Dr. G. A. Somorjai  
Department of Chemistry  
University of California  
Berkeley, California 94720

Dr. J. Murday  
Naval Research Laboratory  
Surface Chemistry Division (6170)  
455 Overlook Avenue, S.W.  
Washington, D.C. 20375

Dr. J. B. Hudson  
Materials Division  
Rensselaer Polytechnic Institute  
Troy, New York 12181

Dr. Theodore E. Madey  
Surface Chemistry Section  
Department of Commerce  
National Bureau of Standards  
Washington, D.C. 20234

Dr. J. E. Demuth  
IBM Corporation  
Thomas J. Watson Research Center  
P.O. Box 218  
Yorktown Heights, New York 10598

Dr. M. G. Lagally  
Department of Metallurgical and Mining Engineering  
University of Wisconsin  
Madison, Wisconsin 53706

Dr. R. P. Van Duyne  
Chemistry Department  
Northwestern University  
Evanston, Illinois 60637

Dr. J. M. White  
Department of Chemistry  
University of Texas  
Austin, Texas 78712

Dr. D. E. Harrison  
Department of Physics  
Naval Postgraduate School  
Monterey, California 93940

Dr. W. Kohn  
Department of Physics  
University of California, San Diego  
La Jolla, California 92037

Dr. R. L. Park  
Director, Center of Materials Research  
University of Maryland  
College Park, Maryland 20742

Dr. W. T. Peria  
Electrical Engineering Department  
University of Minnesota  
Minneapolis, Minnesota 55455

Dr. Keith H. Johnson  
Department of Metallurgy and Materials Science  
Massachusetts Institute of Technology  
Cambridge, Massachusetts 02139

Dr. S. Sibener  
Department of Chemistry  
James Franck Institute  
5640 Ellis Avenue  
Chicago, Illinois 60637

Dr. Arnold Green  
Quantum Surface Dynamics Branch  
Code 3817  
Naval Weapons Center  
China Lake, California 93555

Dr. A. Wold  
Department of Chemistry  
Brown University  
Providence, Rhode Island 02912

Dr. S. L. Bernasek  
Department of Chemistry  
Princeton University  
Princeton, New Jersey 08544

Dr. P. Lund  
Department of Chemistry  
Howard University  
Washington, D.C. 20059
ABSTRACTS DISTRIBUTION LIST, 056/625/629

Dr. R. G. Wallis  
Department of Physics  
University of California  
Irvine, California 92664

Dr. D. Ramaker  
Chemistry Department  
George Washington University  
Washington, D.C. 20052

Dr. J. C. Hemminger  
Chemistry Department  
University of California  
Irvine, California 92717

Dr. T. F. George  
Chemistry Department  
University of Rochester  
Rochester, New York 14627

Dr. G. Rubloff  
IBM  
Thomas J. Watson Research Center  
P.O. Box 218  
Yorktown Heights, New York 10598

Dr. Horia Metiu  
Chemistry Department  
University of California  
Santa Barbara, California 93106

Dr. W. Goddard  
Division of Chemistry  
California Institute of Technology  
Pasadena, California 91125

Dr. J. T. Keiser  
Department of Chemistry  
University of Richmond  
Richmond, Virginia 23173

Dr. R. W. Plummer  
Department of Physics  
University of Pennsylvania  
Philadelphia, Pennsylvania 19104

Dr. E. Yeager  
Department of Chemistry  
Case Western Reserve University  
Cleveland, Ohio 41106

Dr. N. Winograd  
Department of Chemistry  
Pennsylvania State University  
University Park, Pennsylvania 16802

Dr. Roald Hoffmann  
Department of Chemistry  
Cornell University  
Ithaca, New York 14853

Dr. A. Steckl  
Department of Electrical and Systems Engineering  
Rensselaer Polytechnic Institute  
Troy, New York 12181

Dr. G. H. Morrison  
Department of Chemistry  
Cornell University  
Ithaca, New York 14853

Dr. P. Hansma  
Physics Department  
University of California  
Santa Barbara, California 93106

Dr. J. Baldeschwieler  
California Institute of Technology  
Division of Chemistry  
Pasadena, California 91125
ABSTRACTS DISTRIBUTION LIST, 056/625/629

Dr. J. E. Jensen
Hughes Research Laboratory
3011 Malibu Canyon Road
Malibu, California 90265

Dr. J. H. Weaver
Department of Chemical Engineering
and Materials Science
University of Minnesota
Minneapolis, Minnesota 55455

Dr. W. Knauer
Hughes Research Laboratory
3011 Malibu Canyon Road
Malibu, California 90265

Dr. C. B. Harris
Department of Chemistry
University of California
Berkeley, California 94720

Dr. W. Goddard
Division of Chemistry
California Institute of Technology
Pasadena, California 91125

Dr. F. Kutzler
Department of Chemistry
Box 5055
Tennessee Technological University
Cookeville, Tennessee 38501

Dr. A. Reisman
Microelectronics Center of North Carolina
Research Triangle Park, North Carolina 27709

Dr. D. DiLella
Chemistry Department
George Washington University
Washington D.C. 20052

Dr. M. Grunze
Laboratory for Surface Science and Technology
University of Maine
Orono, Maine 04469

Dr. R. Reeves
Chemistry Department
Rensselaer Polytechnic Institute
Troy, New York 12181

Dr. J. Butler
Naval Research Laboratory
Code 6115
Washington D.C. 20375

Dr. L. Interante
Chemistry Department
Rensselaer Polytechnic Institute
Troy, New York 12181

Dr. Irvin Heard
Chemistry and Physics Department
Lincoln University
Lincoln University, Pennsylvania 19352

Dr. K.J. Klaubunde
Department of Chemistry
Kansas State University
Manhattan, Kansas 66506
