We calculate the local density of states between the barriers of a double-barrier resonant tunneling structure within the context of a simplified model. As the area of the barriers increases, there is a smooth crossover in the density of states from a three-dimensional square root of energy behavior to a two-dimensional step-like behavior. The local one-dimensional density of states corresponding to a fixed electron momentum transverse to the barriers is also calculated and shows sharp peaks at energies corresponding to the quasi-bound states between the wells. The width of the lowest quasi-bound state is computed as a function of barrier area.

1. INTRODUCTION

Recent advances in semiconductor growth techniques have led to a widespread interest in the physics of ultra-small semiconducting systems. Quantum wells, superlattices, double-barrier resonant tunneling structures, and a variety of other exotic structures have become the objects of extensive investigation [1,2]. The interest in these ultra-small systems is motivated by two factors. First, their optical and electrical properties have quasi-two-dimensional (2-d) features which frequently offer distinct advantages in device applications. Second, actual physical systems whose electron dynamics are quasi-2-d provide one with a rich testing ground for theoretical models.

One of the systems attracting considerable attention is the double-barrier resonant tunneling (DBRT) structure [3]. A typical structure consists of two thin -50 Å AlGaAs layers, separated by an equally thin (-50 Å) GaAs layer, all of which are embedded in a single GaAs crystal. The regions to the left and right of the barriers (usually beyond spacer layers) are n-doped and usually electrically contacted for transport studies. Current-voltage characteristics of this device show an enhancement in the current when the applied voltage aligns the quasi-Fermi energy of incoming electrons with the energies of the quasi-bound states in the quantum well region. A number of theoretical calculations have been done to describe the nonlinear current response [4-16] in this system. However, controversy still exists regarding the basic mechanism behind the nonlinearity [14,15,17-20]. Despite the large number of studies to date, we have not found in the literature any calculation of the local density of states (DOS) for even a highly simplified model of a DBRT structure. The local DOS provides information about resonant states and gives one a quantitative measure of the extent to which the dynamics are quasi-2-d. The purpose of this paper is to present such a calculation.

In section 2, using a simple model potential, we calculate the eigenvalues and eigenfunctions of an effective mass Schrödinger equation. These results are used in section 3 to compute the local DOS in the quantum well region of the potential. In section 4, we relate this local DOS to an integral of a one-dimensional (1-d) DOS. This latter DOS has sharp peaks at energies corresponding to the quasi-bound states between barriers.

2. THE MODEL

We consider a simplified model, which is defined by the following effective mass Hamiltonian:

\[
H = -\frac{\hbar^2}{2m_0} \nabla^2 + V(z),
\]

where \( m_0 \) is the effective mass of electrons at the bottom of the GaAs conduction band and the double barrier potential, \( V(z) \), is

\[
V(z) = V_0 \delta(z - a) + V_0 \delta(z - a).
\]
In this model, the two AlGaAs potential barriers have been replaced by delta function barriers of strength $V_0$, separated by a distance $2a$ along the $z$-axis (the growth direction). The parameter $V_0$ is given by

$$V_0 = \frac{c}{2} \Delta V_c,$$

where $\Delta V_c$ is the conduction band discontinuity and $b$ is the barrier width.

We solve the one-electron Schroedinger equation

$$H\psi(\mathbf{r}) = E\psi(\mathbf{r}),$$

subject to periodic boundary conditions in the $x$- and $y$-directions

$$\psi(x+L, y, z) = \psi(x, y, z),$$

$$\psi(x, y+L, z) = \psi(x, y, z).$$

Since equation (4) is separable, we can write the wavefunction in the product form

$$\psi(\mathbf{r}) = \frac{1}{L} e^{\frac{i\mathbf{k}\cdot\mathbf{r}}{2}},$$

where $\mathbf{k} = (k_x, k_y, 0)$, $k_x = \frac{2\pi n_x}{L}$, $k_y = \frac{2\pi n_y}{L}$, and $n_x, n_y$ take the integer values $0, \pm1, \pm2, \ldots$. The $z$-part of the wavefunction, $\psi(z)$, satisfies the reduced equation

$$\psi''(z) + \frac{2m_c}{\hbar^2} [E - V(z)]\psi(z) = 0,$$

where $E = E - \frac{\hbar^2 k_z^2}{2m_c}$. For $\psi(z)$, we choose the vanishing boundary conditions

$$\psi(-\frac{L}{2}) = 0,$$

$$\psi(\frac{L}{2}) = 0.$$  

The presence of the delta functions imposes two jump discontinuity conditions on the derivative of $\psi(z)$ at the delta function positions, which are given by

$$\psi'(-a + 0^+) - \psi'(-a - 0) = \gamma \psi(-a),$$

$$\psi'(a + 0^+) - \psi'(a - 0^+) = \gamma \psi(a),$$

$$\gamma = \frac{2m_c}{\hbar^2} \Delta V_c.$$
where \( Y = 2m_o V_o \hbar^2 \), and \( 0^+ \) is a positive infinitesimal quantity. These two conditions may be found by integrating equation (7) over the infinitesimal intervals \((-a - 0^+, -a + 0^+)\) and \((a - 0^+, a + 0^+)\). In addition, we require the wavefunction to be continuous at the delta function positions

\[
\psi(-a - 0^+) = \psi(-a + 0^+) ,
\]

\[
\psi(a - 0^+) = \psi(a + 0^+) .
\]

To look for a solution to equation (7), we take advantage of symmetry and solve the eigenvalue problem in the region \( 0 < z < L/2 \). We then look for even wavefunctions of the form

\[
\psi_{ok}(z) = \begin{cases} 
A_1(k) \cos(kz) & , \quad 0 < z < a , \\
A_2(k) \cos(kz) + A_3(k) \sin(kz) & , \quad a < z < L/2 ,
\end{cases}
\]

and odd wavefunctions of the form

\[
\psi_{ok}(z) = \begin{cases} 
B_1(k) \sin(kz) & , \quad 0 < z < a , \\
B_2(k) \cos(kz) + B_3(k) \sin(kz) & , \quad a < z < L/2 .
\end{cases}
\]

For the even wavefunctions, when we impose the conditions in equations (8b), (9b), and (10b), we get a set of three homogeneous equations for \( A_1(k) \), \( A_2(k) \), and \( A_3(k) \). To have a nontrivial solution, we require the determinant of the coefficient matrix to vanish. This gives an equation for the allowed \( k \)'s which label the even-parity states:

\[
\frac{Y}{k} \cos(ka) \sin(kl - ka) + \cos(kl) = 0 .
\]

Here we have used the convenient definition \( \ell = L/2 \). Solving the three homogeneous equations for the ratios, we find

\[
\frac{A_3(k)}{A_1(k)} = \frac{Y}{k} \cos^2(ka) ,
\]

\[
\frac{A_2(k)}{A_1(k)} = 1 - \frac{Y}{k} \sin(ka) \cos(ka) .
\]

Applying the same boundary conditions to the odd solutions given in equation (12) and setting the determinant of the coefficient matrix to zero, we obtain the equation satisfied by the allowed wavevectors labelling the odd-parity states:

\[
\frac{Y}{k} \sin(ka) \sin(kl - ka) + \sin(kl) = 0 .
\]
Solving the associated system of equations leads to

\[
\frac{B_2(k)}{B_1(k)} = -\frac{\gamma}{k} \sin^2(ka), \quad (14b)
\]
\[
\frac{B_3(k)}{B_1(k)} = 1 + \frac{\gamma}{k} \sin(ka) \cos(ka). \quad (14c)
\]

The constants \(A_1\) and \(B_1\) are evaluated from the normalization condition

\[
\int_{-l}^{l} |\psi_{ak}(z)|^2 dz = 1,
\]

where \(a = e (o)\) for the even (odd) solutions. We find

\[
\frac{1}{A_1^2(k)} = l \left[ 1 + \frac{\sin(2ka)}{2k} + \left( 1 - \frac{a}{l} \right) \left( \frac{\gamma}{2k} \right)^2 \sin^2(2ka) - \frac{\gamma}{k} \sin(2ka) + \left( \frac{\gamma}{k} \right)^2 \cos^2(ka) \right]
\]
\[
+ \frac{1}{k^2} \cos k(l+a) \sin k(l-a) \left[ \left( \frac{\gamma}{2k} \right)^2 \sin^2(2ka) - \frac{\gamma}{k} \sin(2ka) - \left( \frac{\gamma}{k} \right)^2 \cos^2(ka) + 1 \right]
\]
\[
- \frac{2}{k^2} \frac{\gamma}{k} \left[ \frac{\gamma}{2k} \sin(2ka) - 1 \right] \sin^2(ka) \sin k(l+a) \sin k(l-a)
\]

and

\[
\frac{1}{B_1^2(k)} = l \left[ 1 - \frac{\sin(2ka)}{2k} + \left( 1 - \frac{a}{l} \right) \frac{\gamma}{k} \left[ \sin(2ka) + \frac{\gamma}{k} \left[ \sin^2(ka) + \frac{1}{4} \sin^2(2ka) \right] \right]
\]
\[
+ \frac{1}{k^2} \cos k(l+a) \sin k(l-a) \left[ \left( \frac{\gamma}{k} \right)^2 \left[ \sin^2(ka) + \frac{1}{4} \sin^2(2ka) \right] - \frac{\gamma}{k} \sin(2ka) - 1 \right]
\]
\[
- \frac{2}{k^2} \frac{\gamma}{k} \left[ \frac{\gamma}{2k} \sin(2ka) + 1 \right] \sin^2(ka) \sin k(l+a) \sin k(l-a)
\]

The energy eigenvalues associated with the eigenfunctions in equation (5) are given by

\[
E_{k\alpha} = \frac{\hbar^2 k^2}{2m_c}.
\]

With vanishing boundary conditions on \(\psi(z)\) at \(z = \pm l\), the limit of zero strength \(\delta\)-functions \((\gamma \to 0)\) is identical to the limit where the delta functions are placed on the boundaries \((a = \ell)\). In both cases one recovers the 1-d particle in a box problem, where \(A_2/A_1 = B_2/B_1 = 0\), \(A_0/A_1 = B_3/B_1 = 1\), and \(A_1 = B_1 = (2/L)^{1/2}\).

8
3. THREE-DIMENSIONAL DENSITY OF STATES

We now construct the single-particle Green's function

\[ G(\mathbf{r}, \mathbf{r}'; E) = \sum_{\alpha} \sum_{\mathbf{k}} \frac{\psi_{\alpha\mathbf{k}}(\mathbf{r}) \psi_{\alpha\mathbf{k}}^*(\mathbf{r}')}{E - E_\mathbf{k} + \text{i} \epsilon}, \]  

where the eigenstates \( \psi_{\alpha\mathbf{k}}(\mathbf{r}) \) are given by equations (6), (11), and (12), and \( \mathbf{k} = (k_x, k_y, k_z) \). Here \( \alpha \) (equal to e or o) labels a state's parity, \( k_z \) is given by the roots of equations (13a) and (14a) for even- and odd-parity states, respectively. Using the Green's function, we calculate the local DOS (including both spins):

\[ D(z, E) = -\frac{2}{\pi} \text{Im} G(\mathbf{r}, \mathbf{r}; E) \]

\[ = \frac{2}{L^3} \sum_{\alpha} \sum_{\mathbf{k}} \sum_{\mathbf{k}'} |\psi_{\alpha\mathbf{k}}(z)|^2 \delta(E - E_{\mathbf{k}}) , \]

In the limit when the system size goes to infinity, with \( a \) being constant, the density of allowed wavevectors becomes \( 2\pi L \). This allows us to change the sums in equation (20) to integrals:

\[ D(z, E) = \frac{L}{4\pi^3} \int_{-\infty}^{\infty} d^2k \int_{0}^{\infty} dk \sum_{\alpha} |\psi_{\alpha\mathbf{k}}(z)|^2 \delta(E - E_{\mathbf{k}}) . \]

The integration over \( k_z = (k_x, k_y) \) is over all positive and negative wavevectors, whereas the \( z \)-component wavevector, \( k_z \), is integrated over positive values only. Using the explicit form of the wavefunctions and changing to spherical momentum coordinates, we have for the region \(-a < z < a\)

\[ D(z, E) = \frac{1}{8a_0 E_0} \int_0^{(\pi/2)} \frac{d\theta}{E/E_0} \left[ F_e(q) \cos^2(\frac{\pi}{a} q) + F_o(q) \sin^2(\frac{\pi}{a} q) \right] , \]

where

\[ F_e(q) = \frac{q^2}{q^2 + U^2 \cos^2(q) - Uq \sin(2q)} = \frac{1}{|1 + \frac{iU}{2q} (1 + e^{i2q})|^2} , \]  

\[ F_o(q) = \frac{q^2}{q^2 + U^2 \sin^2(q) + Uq \sin(2q)} = \frac{1}{|1 + \frac{iU}{2q} (1 - e^{i2q})|^2} . \]
the dimensionless potential strength $U$ is defined by $U = \frac{\alpha}{\hbar} = \frac{2m\alpha^2}{\hbar^2}$, and a convenient energy scale, $E_0 = \frac{\pi^2\hbar^2}{8m\alpha^2}$, has been introduced. The functions $F_e(q)$ and $F_o(q)$ are related to the wavefunction amplitudes by

$$\lim_{a/\lambda \to 0} A_e(q/a) = F_e(q),$$

$$\lim_{a/\lambda \to 0} B_o(q/a) = F_o(q).$$

The local DOS given by equation (22) is a sum of two terms. The term containing $F_e(q)$ gives the local density of even states in the well, and the term with $F_o(q)$ gives the local density of odd states. Each function $F_\alpha(q)$, $\alpha = e$ or $o$, is an even function with an infinite sequence of (complex conjugate) pairs of simple poles in the complex $q$-plane (see fig. 1). Each pair of poles with Re$(q) > 0$ corresponds to one resonance. In the limit $U \to 0$ (no delta-function barriers), these poles move away from the real-$q$ axis to infinity and $F_\alpha(q) \to 1$ on the real axis. In this limit, $D(z,E)$ is simply the local DOS for a free electron gas in a box of volume $2aL^3$.

---

Figure 1. Locations of poles of $F_e(q)$ are shown for $U = 3$. Poles of $F_o(q)$ (not shown) lie between poles of $F_e(q)$. 
As we approach the limit of strong barriers, \( U \gg 1 \), the poles of the functions \( F_\alpha(q) \) move in toward the real axis in pairs (one pole above and one pole below) (see fig. 1). In the region of \( U \gg 1 \), and \( 0 < q \leq U \), the functions \( F_\alpha(q) \) are well represented by a sum of Lorentzians

\[
F_\alpha(q) = \sum_n \frac{\Gamma_n}{(q - q_{an})^2 + \Gamma_n^2},
\]

where the real and imaginary positions of the poles, \( q_{an} \pm i\Gamma_n \), are functions of \( U \). For \( U \to \infty \) we have \( \Gamma_n \to 0 \), \( q_{en} \to (2n + 1)\pi/2 \), and \( q_{on} \to n\pi \). In this limit we find

\[
\lim_{U \to \infty} F_\alpha(q) \to \pi \sum_n \delta(q - q_{an}).
\]

Rather than look at the local DOS in more detail, we consider its integral over the well volume

\[
N(E) = \frac{mL^2}{\pi^2 n^2} \int_0^{(\pi/2)(E/E_0)^{1/2}} dq \left\{ F_e(q) + F_0(q) + \left[ F_e(q) - F_0(q) \right] \frac{\sin(2q)}{2q} \right\}.
\]

The function \( N(E) \) gives the number of states in the well per unit energy interval. In the limit of weak barriers, \( U \ll 1 \), we find

\[
N(E) \to U \to 0 \quad \frac{1}{2\pi^2} \left( \frac{2m}{n^2} \right)^{1/2} 2aL^2\sqrt{E},
\]

which is the DOS for a free electron gas in a volume \( 2aL^2 \).

In the limit of strong barriers, \( U \gg 1 \), we find

\[
N(E) \to U \to \infty \quad \frac{mL^2}{\pi^2 n^2} \sum_{n=1}^{\infty} \theta(E - n^2E_0),
\]

where \( \theta(x) = 1 \) for \( x > 0 \) and \( \theta(x) = 0 \) for \( x < 0 \). This is the well-known staircase-like DOS one would expect in a quasi-2-d system. For intermediate values of \( U \), the DOS \( N(E) \) is plotted in figure 2.
Figure 2. Dimensionless density of states between barriers, 
\( \left( \frac{\pi^2 \hbar^2}{m L^2} \right) N(E) \), is plotted as a function of dimensionless electron energy, \( E/E_0 \), for values of \( U = 0, 1, 3, 5, 10, 20 \). Higher values of \( U \) correspond to an increased step-like structure.

4. ONE-DIMENSIONAL DENSITY OF STATES

Since the Hamiltonian in equation (1) conserves transverse electron momentum, \( k_x \) and \( k_y \) are good quantum numbers, and an electron placed in a state of definite \( k \) will remain in this state indefinitely. With this in mind we consider the Green's function

\[
G_{1-d}(\mathbf{r}, \mathbf{r}'; E) = \sum_{\alpha} \sum_{k} \frac{\psi_{\alpha k}(\mathbf{r}) \psi^{*\alpha \dagger}(\mathbf{r}')}{E - E_k + i\delta},
\]

in which the summation on \( \mathbf{k} \) is omitted. Using this Green's function we define the 1-d local DOS (including both spins) as
\[
D_{1-d}(z, E_z) = -\frac{2}{\pi} \text{Im} \ G_{1-d}(\vec{r}, \vec{r}; E)
\]
\[
= \frac{1}{L^2} \sum_{\alpha} \left| \psi_{\alpha k_a}(z) \right|^2 \delta \left( E - \frac{\hbar^2 k_a^2}{2m_c} - \frac{\hbar^2 k_\perp^2}{2m_c} \right),
\]
where \(\psi_{\alpha k_a}\) is given in equations (11) and (12), and \(E_z = E - \frac{\hbar^2 k_\perp^2}{2m_c}\).

The function \(D_{1-d}(z, E_z)\) gives the number of states (labelled by \(\alpha\) and \(k_a\)) per unit volume, for a given \(k_\perp\). This function displays peaks which are associated with the resonances. Substituting the explicit form of the wavefunctions into equation (31), we find

\[
D_{1-d}(z, E_z) = \frac{1}{2aL^2E_0\sqrt{\epsilon}} \left[ F_e \left( \frac{\pi}{2\sqrt{\epsilon}} \right) \cos \left( \frac{\pi z}{2a\sqrt{\epsilon}} \right) + F_o \left( \frac{\pi}{2\sqrt{\epsilon}} \right) \sin \left( \frac{\pi z}{2a\sqrt{\epsilon}} \right) \right].
\]

where the dimensionless z-component of energy, \(\epsilon\), is defined by \(\epsilon = E_z/E_0\).

Again, rather than looking at this in more detail, we consider the integral of \(D_{1-d}(z, E_z)\) over the well volume

\[
N_{1-d}(E_z) = \int_{\text{well}} D_{1-d}(z, E_z) \, d^3r
\]
\[
= \frac{1}{2E_0\sqrt{\epsilon}} \left[ F_e \left( \frac{\pi}{2\sqrt{\epsilon}} \right) \left[ 1 + \frac{\sin(\pi\sqrt{\epsilon})}{\pi\sqrt{\epsilon}} \right] + F_o \left( \frac{\pi}{2\sqrt{\epsilon}} \right) \left[ 1 - \frac{\sin(\pi\sqrt{\epsilon})}{\pi\sqrt{\epsilon}} \right] \right].
\]

This function specifies the number of states in the well labelled by \(\alpha, k_a\), per unit energy, for a given \(k_\perp\). In the limit of weak barriers, \(U \to 0\), the function \(N_{1-d}(E_z) \to 1/(E_0 e^{1/2})\) which is the DOS for a 1-d free-electron gas. In the limit of strong barriers, \(U \to \infty\), the number of states in the well per unit energy is just a sum of delta functions. In this limit the resonant states are the eigenstates of the 1-d particle in a box problem, and the resonance peaks shift to the appropriate limiting eigenvalues. For intermediate values of \(U\) (and energies \(0 < \epsilon < U\)) the function \(N_{1-d}(E_z)\) is approximately a sum of Lorentzians (see fig. 3). The lowest energy peak is composed predominantly of even wavefunctions, while the second peak is composed mostly of the odd wavefunctions. In figure 4 we show the DOS \(N_{1-d}(E)\) for several values of \(U\), in the energy region of the lowest resonant level. The inset of figure 3 shows the peak position of the lowest resonance as a function of
barrier strength $U$. For energies much larger than $U$, $\epsilon >> U$, the functions $F_{\alpha}(\sqrt{\epsilon}/2) + 1$ and the DOS returns to its value in the absence of barriers, $N_{\alpha-d}(E_z) \rightarrow 1/(E_0 \sqrt{\epsilon})$.

Figure 3. On outer axis, a plot of $2E_0N_{1-d}(E_z)$ versus $E_z/E_0$ is shown. On inset, solid line is a plot of energy of lowest resonance (lowest energy peak in density of states) versus dimensionless potential $U$. Vertical distance between dotted curves gives full width at half maximum of lowest resonant level, as a function of $U$. 
5. SUMMARY

Within the context of a simple model for a double-barrier structure, we solved for the normalized eigenstates. Using these eigenstates we calculated the 3-d local DOS between the barriers. This quantity shows a crossover from a 3-d square root of energy behavior to a quasi-2-d staircase-like behavior, as the barrier strength \( U \) is increased. For electron energies \( \epsilon \gg U \) the DOS always returns to the free electron DOS. We also calculated the 1-d DOS for a given transverse momentum \( k_\perp \). This quantity shows sharp peaks at energies corresponding to the resonant states. In a more realistic model, one can use the width of the lowest peak in \( N_{1-d}(E_z) \) to reliably estimate the lifetime of the lowest quasi-bound state. The inverse of this lifetime gives an estimate of the characteristic frequency above which the resonant contribution to the current becomes negligible.
