A Further Generalized Kettele Algorithm
With Multiple Constraints

A. Charnes
D. Zhang

Abstract

J.D. Kettele [1], using dynamic programming, developed a simple algorithm (KA) for the optimal redundancy problem in reliability and life testing problems with a single constraint. F. Proschan and T.B. Bray [2] gave a generalization of Kettele's dynamic programming algorithm to include multiple constraints. To solve a much broader class of optimization problems than in [1], R.E. Barlow and F. Proschan generalized the Kettele algorithm (GKA) to apply to strictly increasing separable function problems with a single constraint [3].

In this paper, we consider a still more general optimization model and develop a Further Generalized Kettele Algorithm (FGKA) to apply to multiple constraints, etc. As an example, an integer Lexicographic programming model will be solved (corollary 1; section 2). Furthermore, another form of the more general optimization model is pointed out in section 4 of the paper.

Kettele Algorithms
optimal redundancy
1. Introduction

Kettele [1] presents an algorithm for allocating redundancy so as to maximize system reliability without exceeding a specified cost. Specifically, a system consisting of k "stages" is considered. The system functions if and only if each stage functions. Stage i consists of \( n_i \) (to be determined) units of type i in parallel, so that stage functions if and only if at least one of \( n_i \) units of type i functions, \( i = 1, 2, \ldots, k \). Suppose unit i has a "cost" \( c_i \), \( i = 1, \ldots, k \). A unit of type i has probability \( p_i \) of functioning, independently of the functioning or nonfunctioning of the other units of the system. Thus system reliability is given by

\[
P(n) = \prod_{i=1}^{k} (1 - (1 - p_i)^{n_i})
\]

Then the problem considered in [1] is

\[
\max \prod_{i=1}^{k} (1 - (1 - p_i)^{n_i})
\]

s.t. \( \sum_{i=1}^{k} c_i n_i \leq c \)

\( n_i \geq 0, \ \text{integer}, \) \hspace{1cm} (1)

where c is a limit "cost".

Proschans and Bray [2] generalize KA to solve the more general problem of maximizing system reliability without exceeding any of several linear constraints, i.e., specifically,

\[
\max \prod_{i=1}^{k} (1 - (1 - p_i)^{n_i})
\]

s.t. \( \sum_{i=1}^{k} c_{ij} n_i \leq c_j \) \hspace{1cm} (j = 1, 2, \ldots, r)

\( n_i \geq 0, \ \text{integer}, \)

where \( c_{ij} \) is the "cost" of the unit i of the jth type, \( i = 1, \ldots, k; \ j = 1, \ldots, r \), and \( c_j \) is the limit "cost" of the jth type. As an example, the first type of cost might be money, the second weight, the third volume, the fourth population rate.

Barlow and Proschan [3] then give a Generalized Kettele Algorithm to solve an optimization model more general than in [1] as follows. Suppose \( x_1, \ldots, x_k \) are k variables
called "decision variables"; \( x_i \in S_i = \{ x_i^{(1)} < x_i^{(2)} < \ldots \} \), \( i = 1, \ldots, k \). Let \( \bar{x}_i = (x_1, \ldots, x_i) \), \( i = 1, \ldots, k \). Assume \( f_1, \ldots, f_k \) are strictly increasing functions, with \( y_1(x_1) = f_1(x_1), y_2(x_2) = f_2(y_1, x_2), \ldots, y_k(x_k) = f_k(y_{k-1}, x_k) \). Similarly, assume \( g_1, \ldots, g_k \) are strictly increasing functions, with \( z_1(x_1) = g_1(x_1), z_2(x_2) = g_2(z_1, x_2), \ldots, z_k(x_k) = g_k(z_{k-1}, z_k) \). It is suggestive to call \( \bar{x}_i \) an "allocation" of order \( i \), \( y_i \) a "payoff" of order \( i \), and \( z_i \) a "cost" of order \( i \) \( (i = 1, \ldots, k) \) even though the model is more general than these terms would indicate.

The Barlow and Proschan (B-P) model is

\[
\begin{align*}
\text{max} & \quad y_k(\bar{x}_k), \\
\text{s.t.} & \quad z_k(\bar{x}_k) \leq c, \\
\bar{x}_k & = (x_1, \ldots, x_k) \in S_1 \times \cdots \times S_k,
\end{align*}
\]

(2)

where \( c \) is a limit "cost". In this model there is only a single constraint. The cost \( z_k \) may not be a sum of linear functions \( c_j x_j, j = 1, \ldots, k \). It is strictly increasing in the number of spares of each type.

B-P gave some examples (see examples and exercises, [3]) and pointed out that a great many other models requiring optimization subject to a constraint arising in reliability, and more generally in operations research, are special cases of the general optimization model. Such problems may be solved by the Generalized Kettlele Algorithm [3].

In this paper, we propose a more general optimization model and develop an associated Further Generalized Kettlele Algorithm (FGKA). Thereby, the optimal problems which can be solved by FGKA will not confine to a simple numerical objective function or a single constraint.

**Example 1:** An Integer Lexicographic Problem

\[
\begin{align*}
\text{max} & \quad \left( y_k^{(1)}(\bar{x}_k), y_k^{(2)}(\bar{x}_k), \ldots, y_k^{(i)}(\bar{x}_k) \right), \\
\text{s.t.} & \quad z_k^{(i)}(\bar{x}_k) \leq c_i, \quad i = 1, 2, \ldots, m,
\end{align*}
\]

(3)
where $c_i$ is a constant, $i = 1, \ldots, m$; $\tilde{x}_i = (x_1, \ldots, x_i)$, and $x_j$ is a real variable, $i, j = 1, \ldots, k$; $f_1^{(i)}, \ldots, f_k^{(i)}$ all are strictly increasing functions with real values, and

$$y_1^{(i)}(x_j) = f_1^{(i)}(x_j), \quad y_2^{(i)}(x_k) = f_2^{(i)}(y_1^{(i)}, x_2), \quad \ldots, \quad y_k^{(i)}(x_k) = f_k^{(i)}(y_{k-1}^{(i)}, x_k), \quad j = 1, \ldots, l; \quad g_1^{(i)}, \ldots, g_k^{(i)}$$

all are strictly increasing functions with real values, and $z_1^{(i)}(x_1) = g_1^{(i)}(x_1), z_2^{(i)}(x_2) = g_2^{(i)}(z_1^{(i)}, x_2), \ldots, z_k^{(i)}(x_k) = g_k^{(i)}(z_{k-1}^{(i)}, x_k), z_{i+1}^{(i)}(z_i^{(i)}, x_i), i \geq 2, j = 1, \ldots, m; (y_1, \ldots, y_k^{(i)})$ belongs to $l$-dimensional real vector space $\mathbb{R}^l$ with the Lexicographic ordering.

The Lexicographic problem is a special case of our still more general optimization model. And as we know, an integer bottleneck problem and an integer time-cost problem are in some sense special cases of the integer Lexicographic problems.
2. Still More General Optimization Model and FGKA

Now, let us give the still more general optimization model. Suppose $S_i$ is a countable well ordered set, $S_i = \{ x_i^{(1)} < x_i^{(2)} < \ldots \}$, $i = 1, 2, \ldots, k$. $Y$, $Z$ both are ordered sets. In $Z$ there exists a maximal element $z_0$ (or $\infty$). Let $x_i$ represent a variable called a "decision" variable, $x_i \in S_i$, and $\bar{x}_i = (x_1, x_2, \ldots, x_i)$. Let $f_1, f_2, \ldots, f_k; g_1, g_2, \ldots, g_k$ all be strictly increasing functions, with $y_1(x_1) = f_1(x_1), y_2(x_2) = f_2(y_1, x_2), \ldots, y_k(\bar{x}_k) = f_k(y_{k-1}, x_k)$ and $y_1(y_1(\bar{x}_k)) = y_k(y_{k-1}, \bar{x}_k)$ and $y_i \in Y; z_1(x_1) = g_1(x_1), z_2(x_2) = g_2(z_1, x_2), \ldots, z_k(x_k) = g_k(z_{k-1}, x_k)$ and $z_i \in Z, i = 1, 2, \ldots, k; \text{ for } i > 1, g_i(z_0, x_i) = z_o, z_{i-1} = g_i(z_{i-1}, x_i^{(1)})$.

Call $\bar{x}_i$ an allocation of order $i$, $y_i$ a payoff of order $i$, and $z_i$ a cost of order $i$, $i = 1, 2, \ldots, k$.

The still more general optimization model is

$$\text{Max } y_k(\bar{x}_k),$$
$$\text{s.t. } z_k(\bar{x}_k) \leq c, \quad (4)$$

where $c \in Z \setminus \{ z_0 \}$, $\bar{x}_k = (x_1, x_2, \ldots, x_k)$. $x_j \in S_j, j = 1, 2, \ldots, k$.

Assume that (4) and $z_j \geq c, j = 1, \ldots, k$ all have solutions.

**Definition 1:** Allocation $\bar{x}_i$ dominates allocation $\bar{x}'_i$ if

(i) $y_i(\bar{x}_i) > y_i(\bar{x}'_i)$ and $z_i(\bar{x}_i) \leq z_i(\bar{x}'_i) < z_0$, or

(ii) $y_i(\bar{x}_i) = y_i(\bar{x}'_i)$ and $z_i(\bar{x}_i) < z_i(\bar{x}'_i) < z_0$, or

(iii) $z_i(\bar{x}'_i) = z_0$

We write $\bar{x}_i \Delta > \bar{x}'_i$. We also say the corresponding payoff-cost pair $(y_i, z_i)$ dominates $(y'_i, z'_i)$ and write $(y_i, z_i) \Delta > (y'_i, z'_i)$.

**Definition 2:** $\bar{x}_i$ is called an undominated allocation of order $i$ if there exists no $\bar{x}'_i$ such that $\bar{x}_i \Delta > \bar{x}'_i$. We also say the corresponding payoff-cost pair $(y_i, z_i)$ is undominated.
**Definition 3:** A complete sequence of undominated allocations of order \(i\) (ending in \(x_i^{(n)}\), say) is a sequence of undominated allocations \(x_1^{(1)}, \ldots, x_i^{(n)}\) each of order \(i\), such that

(i) \(y_1(x_1^{(1)}) \leq \ldots \leq y_1(x_i^{(n)})\),

(ii) \(z_1(x_1^{(1)}) \leq \ldots \leq z_1(x_i^{(n)})\), and

(iii) If \(x_i\) is undominated and yields a payoff-cost pair distinct from those of \(x_1^{(1)}, \ldots, x_i^{(n)}\), then \(y_i(x_i) > y_i(x_1^{(n)})\) and \(z_i(x_i) > z_i(x_1^{(n)})\).

We call the corresponding sequence \((y_1^{(1)}, z_1^{(1)}), \ldots, (y_i^{(n)}, z_i^{(n)})\) a complete undominated sequence of payoff-cost pairs of order \(i\).

We now present an algorithm to solve this more general optimization model (4). We shall call it the Further Generalized Kettele Algorithm (FGKA).

**Step 1:** Compute \(y_1 = f_1(x_1^{(1)}), z_1 = g_1(x_1^{(1)})\) for \(i = 1, 2, \ldots, s_1\), where \(z_1^{(s_1)} \leq c\), and \(z_1^{(s_1+1)} > c\). There exists such \(s_1\) since \(z_1(x_1) = z_k(x_1, x_2^{(1)}, \ldots, x_k^{(1)})\) and \(z_k \leq c, z_1 > c\) both have solutions. \((y_1^{(1)}, z_1^{(1)}), \ldots, (y_1^{(s_1)}, z_1^{(s_1)})\) constitute a complete sequence of undominated payoff-cost pairs of order 1 not violating the cost constraint.

**Step 2:** Compute \(y_2 = f_2(y_1, x_2), z_2 = g_2(y_1, x_2)\) for \(i = 1, 2, \ldots, s_1; j = 1, 2, \ldots\) such that \(z_2 \leq c\). Enter the payoff-cost pair \((y_2, z_2)\) in row \(i\), column \(j\) of a table of payoff-cost pairs.

**Step 3:** The lowest cost undominated pair \((y_2^{(1)}, z_2^{(1)})\) in the table is clearly \((y_2, z_2)\) if \(z_2 \leq c\). If \(z_2 > c\), there is no solution.

To determine \((y_2^{(2)}, z_2^{(2)})\), find \((y_2, z_2)\) such that \(y_2 > y_2^{(1)}\) with \(z_2\) minimum among entries satisfying this inequality. If several entries of identical cost qualify, choose the highest payoff \(y_2\). If several entries of identical cost and identical highest payoff qualify, choose one at random, since all are equally cost-effective. The payoff-cost entry so chosen is \((y_2^{(2)}, z_2^{(2)})\).

Continue in this fashion, i.e. having found \((y_2^{(n)}, z_2^{(n)})\), then \((y_2^{(n+1)}, z_2^{(n+1)})\) is the pair \((y_2, z_2)\) such that \(y_2 > y_2^{(n)}\) with \(z_2\) minimum among pairs satisfying this inequality. In case of ties, follow the rules for breaking ties described above.
Stop at \((y_2, z_2)\), where \(s_2\) is determined so that \(z_2^{s_2} \leq c\), while \(z_2^{s_2+1} > c\). Such \(s_2\) exists if there is a solution to (4).

The sequence \(\left(y_2^{(1)}, z_2^{(1)}\right), \ldots, \left(y_2^{(s_2)}, z_2^{(s_2)}\right)\) obtained this way constitutes a complete sequence of undominated payoff-cost pairs of order 2 not exceeding the cost limit \(c\).

**Step 4**: Proceeding in a similar fashion using the payoff-cost pairs \(\{y_{3ij}, z_{3ij}\}\), where \(y_{3ij} = f_3(y_2, z_3), z_{3ij} = g_3(z_2, x_3)\) for \(i = 1, 2, \ldots, s_2; j = 1, 2, \ldots, s_2\), obtain a complete sequence of payoff-cost pairs not violating the cost constraint. Continue in this fashion until at the \(k^{th}\) stage, arrive at the complete sequence of undominated payoff-cost pairs \(\left(y_k^{(1)}, z_k^{(1)}\right), \ldots, \left(y_k^{(s_k)}, z_k^{(s_k)}\right)\), where \(z_k^{(s_k)} \leq c\), while \(z_k^{(s_k+1)} > c\).

**Step 5**: Finally, \(y_k^{(s_k)}\) is the maximum payoff achievable under the cost constraint; the corresponding cost is \(z_k^{(s_k)}\). The allocation \(x^{(s_k)}\) yielding the payoff-cost pair \(\left(y_k^{(s_k)}, z_k^{(s_k)}\right)\) is the solution to (4).

**Theorem 1.** The payoff-cost pair \(\left(y_k^{(s_k)}, z_k^{(s_k)}\right)\) and the allocation \(x^{(s_k)}\) obtained using the FGKA is the solution to the more general optimal model (4). That is, it is the maximum payoff achievable with corresponding cost \(z_k^{(s_k)} \leq c\), the cost constraint.

**Proof.** The argument of the proof is similar to that of the original theorem about the GKA (p. 221, [3]). In the original proof two lemmas are used. They are as follows.

**Lemma 4.5.** (a) Every payoff-cost pair of order 2 obtained by GKA is undominated. (b) Every undominated payoff-cost pair of order 2 may be obtained by the GKA.

**Lemma 4.6.** Let \((y_2, z_2) \gtrdot (y_2', z_2')\), \(y_3 = f_3(y_2, x_3), z_3 = g_3(z_2, x_3)\), \(y_3' = f_3(y_2', x_3)\), and \(z_3' = g_3(z_2', x_3)\). Then \((y_3, z_3) \gtrdot (y_3', z_3')\).
The two lemmas are correct for FGKA. The proof of the former is almost word for word repeat of the original lemma proof. The proof of the latter is little different from the original. By the hypothesis of Lemma 4.6,

(i) \( y_2 > y_2' \) and \( z_2 \leq z_2' < z_0 \), or
(ii) \( y_2 = y_2' \) and \( z_2 < z_2' < z_0 \), or
(iii) \( z_2' = z_0 \).

In cases (i) and (ii), we know \( (y_3, z_3) \gg (y_3', z_3') \). In case (iii), this also holds since \( g_3 \) is monotone and \( z_3' = g_3(z_2', x_3) = z_0 \). Hence, Lemma 4.6 holds for FGKA.

Using the two new lemmas and repeating the argument of the proof of the original theorem 4.7 word by word, we get a proof of Theorem 2.

Q.E.D.

Now we show that the general optimization model (B-P) under multiple constraints is a special case of the still more general optimization model (4).

**Theorem 2.** The problem

\[
\begin{align*}
\text{max} & \quad y_k(x_k), \\
\text{s.t.} & \quad z_k^{(i)}(x_k) \leq c_i, \quad i = 1, 2, \ldots, m, \\
& \quad \tilde{x} = (x_1, x_2, \ldots, x_k) \in S_1 \times S_2 \times \ldots \times S_k,
\end{align*}
\]

(5)

where \( S_j, y_i, x_j, \tilde{x}_i, Y_j, z_j^{(i)} \) all are as in the more general optimization model; \( Z^{(i)} \) is an ordered set without assuming a maximal element, is a special case of the still more general optimization model (4).

**Proof.** Let \( Z_0 = Z^{(1)} \times Z^{(2)} \times \ldots \times Z^{(m)} \). Define an equivalence relation \( \equiv \) among elements of \( Z_0 \) as follows. For \( a_i, b_i \in Z^{(i)}, \ i = 1, 2, \ldots, m, \)

\[(a_1, a_2, \ldots, a_m) \equiv (b_1, b_2, \ldots, b_m)\]
if and only if either

(i) \( a_i > c_i \) for some \( i = 2, 3, \ldots, m \), and \( b_j > c_j \) for some \( j = 2, 3, \ldots, m \), or

(ii) \( a_i \leq c_i \) and \( b_i \leq c_i \), \( i = 2, 3, \ldots, m \), and \( a_1 = b_1 \).

Thus we get a collection \( Z \) of classes of equivalent elements of \( Z_0 \). Denote the class including \((c_1, c_2, \ldots, c_m)\) by \( c \in Z \). Define

\[
(a_1, a_2, \ldots, a_m) > (b_1, b_2, \ldots, b_m)
\]

if and only if either

(i) \((a_1, a_2, \ldots, a_m) = z_0 \neq (b_1, b_2, \ldots, b_m)\), where \( z_0 \) is the class whose one of components \( 2, 3, \ldots, m \) is greater than corresponding \( c_i \), or

(ii) \( z_0 \neq (a_1, a_2, \ldots, a_m) \) or \((b_1, b_2, \ldots, b_m)\), where \( a_1 > b_1 \).

Then \( Z \) is an ordered set with a maximal element \( z_0 \).

Here we do not distinguish a class from its representatives.

So, (5) is equivalent to a (4) in which \( z_k \in Z \), \( c \in Z \setminus \{z_0\} \). That is, (5) is a special case of (4).

Q.E.D.

Similarly, we can prove corollary 1. In fact, it can be obtained as a conclusion of Theorem 1 itself, also.

**Corollary 1.** The integer Lexicographic problem (3) is a special case of the more general optimization model (4), or (5).
3. An Example using FGKA

Example 2. Fill Rate Model (compare it to [3], p. 209)

\[
\begin{align*}
\text{max} & \quad R(\mathbf{n}), \\
\text{s.t.} & \quad \sum_{i=1}^{4} n_i c_i \leq c_0, \\
& \quad \sum_{i=1}^{4} n_i w_i \leq w_0, \\
& \quad n_i \geq 0, \text{ integer, } i = 1, 2, 3, 4,
\end{align*}
\]

where \( \mathbf{n} = (n_1, n_2, n_3, n_4) \) is a spares allocation; \( c_i \) is the price of part \( i \), \( c_0 \) is a spares budget constraint; \( w_i \) is the weight of part \( i \), \( w_0 \) is the limit weight of a spare parts kit, \( R(\mathbf{n}) \) is the fill rate,

\[
R(\mathbf{n}) = \sum_{i=1}^{4} \sum_{j=0}^{n_i-1} \frac{(\lambda_i v_i)^j}{j!} e^{-\lambda_i v_i} \left( \sum_{i=1}^{4} \lambda_i \right)^{-j},
\]

where \( \sum_{i=0}^{\infty} = 0 \). Here we assume that

(i) Demands for spares of type \( i \) at a maintenance depot is governed by a Poisson process with demand rate \( \lambda_i \).

(ii) Enough repair facilities are available at the depot so that repair of a failed unit is initiated as soon as it is received.

(iii) The mean time to repair a failed unit of type \( i \) is \( v_i \).

(iv) The cost of purchasing \( n_i \) units of type \( i \) is \( n_i c_i \).

(v) There are \( k \) part types, i.e., \( i = 1, 2, \ldots, k \).

In (6) there are two constraints, which says, that the budget is not to be exceeded nor is the allowed total weight (or volume).
To solve the example, first let $S_i = \{0, 1, 2, \ldots \}$, $Y$ the set $R^1$ of real numbers. To define $Z$, first define an equivalence relation $\equiv$ in the 2-dimensional real vector space $R^2$ as follows.

$$(u_1, u_2) \equiv (v_1, v_2)$$

if and only if either

(i) $u_1 > w_0$ and $v_1 > w_0$, or

(ii) $u_1, v_1 \leq w_0$ and $u_2 = v_2$

Denote $(u_1, u_2)$ by $z_0$ if $u_1 > w_0$. Then let $Z$ be the collection of equivalence classes of elements in $R^2$. Define an order relation $>$ in $Z$:

$$(u_1, u_2) > (v_1, v_2)$$

if and only if either

(i) $u_1 > w_0$ and $v_1 \leq w_0$, or

(ii) $u_1, v_1 \leq w_0$ and $u_2 > v_2$.

Denote $(w_0, c_0)$ by $c$.

The decision variables are to be the number of spares of the $k$ different types, $(n_1, n_2, n_3, n_4)$. The functions of $f_i$ and $g_i$ of the more general model are given by

$$f_1(n_1) = \lambda_1 \sum_{j=0}^{n_1-1} \frac{\left(\lambda_1, u_1\right)^j}{j!} e^{-\lambda_1 u_1}$$

$$f_i(R, n_i) = R + \lambda_i \sum_{j=0}^{n_i-1} \frac{\left(\lambda_i, u_i\right)^j}{j!} e^{-\lambda_i u_i}$$

$$g_1(n_1) = (w_1, n_1, c_1 n_1),$$

$$g_i((w, c), n_i) = (w, c) + (w_i, n_i, c_i n_i).$$

So, all $f_i$ are strictly increasing functions. And all $g_i$ are increasing in $Z$, strictly increasing in $Z \setminus \{z_0\}$. 
For example, consider the situation of a budget \( c_0 = 1500 \) (in dollars), weight limit \( w_0 = 100 \) (in kg), and demand, repair, weight and cost data as shown in Table 1.

Table 1. Input Data for Spares Allocation

To simplify the computation throughout, we drop the denominator to \( \sum_1^k \lambda_i \) in \( R(n) \) since it is constant throughout and just compute the fill rate numerator \( \sum_1^k \lambda_i R(n) \), where

\[
R(n) = \sum_{j=1}^{n-1} \left( \frac{\lambda_i v_i}{j!} \right) e^{-\lambda_i v_i} \quad i = 1, 2, \ldots, k
\]

The steps taken in carrying out FGKA are the following.

1. Noting that \( n_i = 0, 1, 2, \ldots, \), in Step 1 we get

\[
f_1(n_i) = \lambda_i \sum_{j=0}^{n_i-1} \left( \frac{\lambda_i v_i}{j!} \right) e^{-\lambda_i v_i} = .01 \sum_{j=0}^{n_i-1} \left( \frac{1.0}{j!} \right) e^{-1.0}
\]

and

\[
g_1(n_i) = (w_1 n_i, c_i n_i) = (30n_i, 200n_i),
\]

and

\[
c = (w_0, c_0) = (100, 1500)
\]
we get the complete sequence of undominated payoff-cost pairs of order 1,

\[ (y_1^{(1)}, z_1^{(1)}) = (0, (0, 0)), \quad (y_1^{(2)}, z_1^{(2)}) = (0.0368, (30, 200)), \]

\[ (y_1^{(3)}, z_1^{(3)}) = (0.0736, (60, 400)), \quad (y_1^{(4)}, z_1^{(4)}) = (0.0920, (90, 600)). \]

Here \( s_1 = 4 \)

(2) Noting that \( n_2 = 0, 1, 2, \ldots \), in Step 2 and Step 3,

\[ f_2(R_1, n_2) = R + \lambda_2 \sum_{j=0}^{n_2} \frac{(\lambda_2 v_2)^j}{j!} e^{-\lambda_2 v_1} = R + 0.02 \sum_{j=0}^{n_2} \frac{(3.0)^j}{j!} e^{-3.0} \]

and

\[ g_2((w, c), n_2) = (w, c) + (10 n_2, 100 n_2), \]

we get Table 2.

The complete sequence of undominated payoff-cost pairs of order 2 is shown by

\[ \cdots \] in Table 2. Here \( s_2 = 9 \).

(3) Since \( n_3 = 0, 1, 2, \ldots \), in Step 4

\[ f_3(R, n_3) = R + \lambda_3 \sum_{j=0}^{n_3} \frac{(\lambda_3 v_3)^j}{j!} e^{-\lambda_3 v_1} = R + 0.03 \sum_{j=0}^{n_3} \frac{(1.8)^j}{j!} e^{-1.8} \]

and

\[ g_3((w, c), n_3) = (w, c) + (40 n_3, 300 n_3), \]

we obtain Table 3. Here \( s_3 = 9 \), i.e., the complete sequence of undominated payoff-cost pairs of order 3 shown in Table 3 has 9 elements.

(4) Noting that \( n_4 = 0, 1, 2, \ldots \), in Step 4

\[ f_4(R, n_4) = R + \lambda_4 \sum_{j=0}^{n_4} \frac{(\lambda_4 v_4)^j}{j!} e^{-\lambda_4 v_1} = R + 0.01 \sum_{j=0}^{n_4} \frac{(2.0)^j}{j!} e^{-2.0} \]

and

\[ g_4((w, c), n_4) = (w, c) + (5 n_4, 250 n_4), \]

Thus we get Table 4.
The complete sequence of undominated payoff-cost pairs of order 4 is

\[0, 0, 0, 0; \quad 0, 1, 0, 0; \quad 0, 2, 0, 0; \quad 0, 3, 0, 0;\]
\[0, 4, 0, 0; \quad 0, 5, 0, 0; \quad 1, 4, 0, 0; \quad 1, 5, 0, 0;\]
\[2, 4, 0, 0; \quad 2, 4, 0, 1; \quad 2, 4, 0, 2; \quad 1, 5, 0, 3.\]

(5) Finally, a solution of example 3 is

\[(n_1, n_2, n_3, n_4) = (1, 5, 0, 3)\]

with \(\max (\hat{n}) = .02576.\)

Table 3 (y_{3i}j, z_{3i}j)
Table 4 (y_{4ij}, z_{4ij})
4. Another Form of the More General Optimization Model

Corresponding to (1), consider an optimal design problem

$$\min \sum_{i=1}^{k} c_i n_i$$

s.t. $$\prod_{i=1}^{k} (1-(1-p_i)^n) R,$$

$$n_i \geq 0, \text{ integer},$$

where $R$ is a limit reliability, $c_i$, $n_i$, $p_i$ are as in (1).

Generally, let us consider a resolvable problem

$$\min y_k \{x_k\},$$

s.t. $$z_k \{x_k\} \geq c,$$

where $x_k$, $y_k$, $z_k$ and $c$ are as in (4). The only difference is that in $Z$ there exists a minimal element $z_0$, but a maximal element $z_j < c$ has a solution, $j = 1, \ldots, k$. And

$$S_j = \{ \ldots < x_j^{(2)} < x_j^{(1)} \}, \ 1, 2, \ldots, k.$$ (9)

For (7), select positive integers $m_1, \ldots, m_k$ large enough. Let $S_j = \{ 0 < \ldots < m_j - 1 < m_j \}, y_1(x_1) = f_1(x_1) = c_1 x_1, \ y_2(x_2) = f_2(y_1, x_2) = y_1 + c_2 x_2, \ldots, y_k(x_k) = f_k(y_{k-1}, x_k) = y_{k-1} + c_k x_k; z_1(x_1) = (1 - (1 - p_1)^x_1), z_2 = z_1(1 - (1 - p_2)^x_2) \frac{1}{(1 - (1 - p_2)^m_2)}, \ldots,$

$$z_k = z_{k-1}(1 - (1 - p_k)^x_k) \frac{1}{(1 - (1 - p_k)^m_k)}.$$ Then (7) is an example of (8).

We point out that (8) is another form of the more general optimization model (4). Let $S_i^* = \{ x_i^{(1)} \triangle x_i^{(2)} \triangle \ldots \}$ be an ordered set with ordering $\triangle$, $i = 1, \ldots, k$. That is $x_i^{(u)} \triangle x_i^{(v)}$ if and only if $x_i^{(u)} > x_i^{(v)}$. Define a new ordering $\triangle$ in $Y$ such that $a \triangle b$ if and only if $a > b$. Denote the $Y$ with the new relation $\triangle$ by $Y^*$. Similarly, we get $Z^*$. Thus $z_0$ is a maximum in $Z^*$ about the relation $\triangle$. Now, the problem (8) gets a new form as follows.

$$\max y_k \{x_k\},$$

s.t. $$z_k \{x_k\} \triangle c,$$ (10)

where the sign max is about the new relation $\triangle$ in $Y^*$ and the equality sign is the same with the original.
**Theorem 3.** The problem (8) is just another form of the still more general optimization model (4).

Hence, we can use the FGKA solving (8) or (10).

Furthermore, let us look at another optimal design problem

$$\min \sum_{i=1}^{k} c_i n_i$$

s.t. $\prod_{i=1}^{k} \left(1 - \left(1 - p_j^n\right)\right) \geq R$

$$\sum_{i=1}^{k} w_i n_i \leq w,$$

where $w_i$ is the weight of a part of type $i$, $w$ is the total weight limit. Other signs are as in (7).

Generally, we would consider a problem

$$\min y_k(\bar{x}_k),$$

s.t. $z_k(\bar{x}_k) \leq c$

$$z_k(\bar{x}_k) \leq c',$$

where $\bar{x}_k, y_k, z_k, c$ are as in (8), $z_k' \in Z'$, an ordered set with a maximal element $z_0'$, and $c' \in Z' - \{z_0\}$.

**Theorem 4.** The problem

$$\min y_k(\bar{x}_k),$$

s.t. $z_{k_i}(\bar{x}_k) \geq c_i, \quad i = 1, \ldots, m,$$

$$z_{k_i}'(\bar{x}_k) \leq c'_i, \quad i = 1, \ldots, n,$$

$$\bar{x}_k = \{x_1, \ldots, x_k\} \in S_1 x \ldots x S_k,$$

where $S_j, Y, x_j, \bar{x}_j, y_j, \ y_j$, all are as in theorem 2, $z_{k_i}'(\bar{x}_k)$ is as $z_{j_i}'(\bar{x}_k)$ in theorem 2. The corresponding $g_j'$ takes values in the corresponding set $Z'$; $z_{j_i}'(\bar{x}_k) = g_{j_i}'(z_{j_i-1}(\bar{x}_k), x_j)$ is increasing and takes values in an ordered set $Z$ with minimum $z_0$, is a special case of (12).
Proof. Let $Z_0 = Z^{(1)} \times \ldots \times Z^{(m)}$. Define an equivalence relation $\approx$ among elements of $Z_0$ as follows. For $a_i, b_i \in Z^{(i)}$, $i = 1, \ldots, m$, $(a_1, \ldots, a_m) = (b_1, \ldots, b_m)$ if and only if either

(i) $a_i < c_i$ for some $i = 2, \ldots, m$ and $b_j < c_j$ for some $j = 2, \ldots, m$, or

(ii) $a_i \geq c_i$ and $b_i \geq c_i$, $i = 2, \ldots, m$, and $a_1 = b_1$.

Thus we get a collection $Z$ of classes of equivalent elements of $Z_0$. Denote the class including $(c_1, \ldots, c_m)$ by $c$, $(z_k(1)\{x_k\}, \ldots, z_k(m)\{x_k\})$ by $z_k(\{x_k\})$. Define $(a_1, \ldots, a_m) < (b_1, \ldots, b_m)$ if and only if either

(i) $(a_1, \ldots, a_m) = z_0 \neq (b_1, \ldots, b_m)$, where $z_0$ is the class whose one of components $2, 3, \ldots, m$ is less than corresponding $c_i$, or

(ii) $z_0 = (a_1, \ldots, a_m)$ or $(b_1, \ldots, b_m)$, where $a_1 < b_1$.

Then $Z$ is an ordered set with a minimum $z_0$. Similarly, let $Z_0' = Z^{(1)} \times \ldots \times Z^{(n)}$. Define an equivalence relation $\approx$ among elements of $Z_0'$ as follows. For $a_i, b_i \in Z^{(i)}$, $i = 1, \ldots, n$, $(a_1, \ldots, a_n) = (b_1, \ldots, b_n)$ if and only if either

(i) $a_i > c_i'$ for some $i = 2, \ldots, n$ and $b_j > c_j'$ for some $j = 2, \ldots, n$, or

(ii) $a_i \leq c_i'$, $b_i \leq c_i'$, $i = 2, \ldots, n$, and $a_1 = b_1$.

Hence we get a collection $Z'$ of classes of equivalent elements of $Z_0'$. Define the class including $(c_1', \ldots, c_n')$ by $c'$ and $(z_k'(1)\{x_k'\}, \ldots, z_k'(n)\{x_k'\})$ by $z_k'(\{x_k'\})$. Define $(a_1, \ldots, a_m) > (b_1, \ldots, b_n)$ if and only if either

(i) $(a_1, \ldots, a_n) = z_0' \neq (b_1, \ldots, b_n)$, where $z_0'$ is the class whose one of components $2, \ldots, n$ is greater than corresponding $c_i'$, or

(ii) $z_0' = (a_1, \ldots, a_n)$ or $(b_1, \ldots, b_n)$, where $a_1 > b_1$.

Then $Z'$ is an ordered set with a maximal element $z_0'$.

Therefore (13) is equivalent to (12) in which $z_k \in Z$, $c \in Z \setminus \{z_0\}$, $z_k' \in Z'$, $c' \in Z' \setminus \{z_0'\}$. That is, (13) is a special case of (12).

J.D. Kettele, using dynamic programming, developed a simple algorithm (KA) for the optimal redundancy problem in reliability and life testing problems with a single constraint. F. Proschan and T.B. Bray gave a generalization of Kettele's dynamic programming algorithm to include multiple constraints. To solve a much broader class of optimization problems than in [1], R.E. Barlow and F. Proschan generalized the Kettele algorithm (GKA) to apply to strictly increasing separable function problems with a single constraint.
20. Abstract (con't)

In this paper, we consider a still more general optimization model and develop a Further Generalized Kettle Algorithm (FGKA) to apply to multiple constraints, etc. As an example, an integer Lexicographic programming model will be solved (corollary 1, section 2). Furthermore, another form of the more general optimization model is pointed out in section 4 of the paper.
