ABSTRACT

Complex visual simulations can strain the capability of a single workstation. A mix of different workstations is often more economical than the use of a large processor for such simulations. Methods of communicating between such workstations are needed that allow the developer to spend effort on the simulation and not on communications. Simple protocols are developed to support both broadcast and direct-connect communications between workstations using TCP/IP on an Ethernet. Comparisons are made between broadcast and direct connect protocols.

ACKNOWLEDGEMENTS

The author wishes to express his gratitude to a number of people who supported this work. To my advisor, Dr. Michael Zyda, who provided me with the initial idea and direction to start the project, and then stepped back, allowing me the freedom to learn through exploration.

To the following people who provided programs and subroutines which were incorporated into the project:

- Captain Andy Nelson, USMC, for the original versions of the irisflavor Lisp routines.
- Dr. Sehung Kwak, for the conversion of the Explorer Lisp routines to run on the Symbolics as streams.
- Mr. Al Wong, as the guiding light behind the original netV routines, as well as for working broadcast routines, without which, the broadcast routines would never have functioned.
- Dr. Michael Zyda, for the original versions of the mpath, netV, receive, semaphore, send, shareseg, and support routines.

I would like to personally thank my wife, Clare, for the tremendous amount of patience and support provided during all phases of the project. By expertly running a home with two children and shuffling her schedule around the times I absolutely had to work, she provided me the time necessary to fully pursue this project and all others.
I. INTRODUCTION

The Graphics and Video Laboratory of the Department of Computer Science at the Naval Postgraduate School permits the researcher to create three-dimensional visual simulations from digital terrain data [Ref. 1]. Specialized graphics hardware allows the display of such simulations in near-real time. The goal of a good part of the work in the lab is the creation of a movie-like view of movement over and on terrain, with increasingly complex movement animation models. Such projects have strained the equipment's capabilities. One method of increasing available computing power is to harness multiple heterogeneous machines together in some distributed computing organization. It requires communication between the various machines, as well as carefully matching each machine's capabilities to its assigned tasks.

A. PROBLEM

Rapid turnover of inexperienced students at the Naval Postgraduate School makes the creation of complex simulations difficult to manage. The learning curve becomes steeper as the lab's capabilities increase. One of the areas of difficulty has been intercomputer communications. So much time has been spent on designing, coding, and debugging communication software, little has been left for the original research. \textit{V': set out to provide an easy-to-use, yet powerful, set of tools to aid in the development of multi-computer projects.}

1. Approach

A communication protocol can be optimized for large data transfers, or small data transfers, or both. Efforts to optimize for both are both complex and difficult [Refs. 2, 3]. File transfer protocols such as FTP in the Defense Advanced Research Project Agency (DARPA) Internet domain and \textit{uucp} in the UNIX domain can be used for
large data transfers. Their overhead\(^1\) is high. This overhead cannot be tolerated in a real-time problem\(^2\). Our visual simulation efforts rely on small data transfers to communicate among machines. These small messages are typically commands and changing status indicators. Transferring the entire "world view" is only a reasonable task during initialization or reset. Hence, we designed our protocols for small messages.

2. **Design Criteria**

The design criteria for developed protocols were simplicity, ease of use, portability, and efficiency. Rapid turnover of inexperienced students at the Naval Postgraduate School makes simplicity of paramount importance. Inevitably, changes will be required and only a simple protocol is easily modified to take advantage of new capabilities. Much the same argument, and generally good software design practice, make ease of use only slightly less important. Almost all operating system-level aspects are hidden from the application. The number of other machines to be connected to, a use of dynamic memory allocation, and the names of the other machines are the only concerns for the application setting up a connection. The synchronization, or lack thereof, in communication between machines is a design decision.

Portability dictated our use of TCP/IP, an integral part of the Defense Data Network (DDN). Efficient use of processor power was considered more important than efficient use of the network resources. The network is shared by the entire Computer Science Department, but is not heavily loaded.

---

\(^1\) The cost of creating a file and then spawning a process to send it is high. On the receiving end, there is the cost of creating the file and then reading it. Even a zero-cost file transfer protocol will require all this overhead.

\(^2\) Large data transfers, in real-time systems, will not be possible until 100 MByte/Sec networks are commonly available.
B. BACKGROUND

1. Visual Simulation

   a. Vision and Information Presentation

   The eye has the largest bandwidth of any human sensory organ. Proper use of this capability is a challenge to all scientists. Static graphs are used in most disciplines to show the relationships between a limited number of variables. These two-dimensional representations convey information more readily to human beings than would a table of the underlying numbers. [Ref. 4: pp. 8-12]

   Time, a common independent variable, is often one dimension on a graph. The other dimension is a single dependent variable. To portray additional variables in one presentation is a frequently occurring requirement. Various techniques such as multiple colored lines, multiple icons, and perspective drawing are used. With each technique, only a few additional variables are added before the graph becomes incomprehensible.

   Pictures, particularly those in color, have a dense information content. Unless blind, we live in a world of pictures. Human beings can recognize many differences between two similar pictures. One presentation portrays many different variables. When a series of pictures are presented, the time variable is easily correlated to the actual time of presentation. When a series of pictures is presented rapidly, the experience approaches reality, partly explaining the success of moving pictures and television.

   Animation creates visual images with an explicit time dimension, in addition to two or three spatial dimensions. Using actual time to portray the experimental time variable allows at least one more dependent variable on the display. Images can be as simple as a changing graph, or as complex as a feature-length cartoon.
However, animation creates its effect with the playback of prerecorded scenes [Ref. 5]. It is not suitable for providing immediate feedback to a researcher.

b. Definition

*Visual simulation* is the creation, by computer, of a realistic, easily-modified, moving image from the mathematical model of a phenomenon. Realism implies high-resolution, color graphics. Movement implies adequate floating point calculation capacity to recalculate the model and its graphical representation between display refresh cycles. Easy modification implies a well-designed computer application.

*Visual simulation* allows a researcher to experiment easily with his subject. Ideally, we display a realistic approximation of part of the world. The experimenter then manipulates some part of this *visual simulation* and receives immediate visual feedback. The rapidly refreshed display is one key to visual realism. Such a display allows the direct manipulation of the *visual simulation*, making it easy and intuitive to use [Ref. 6]. Ease of use allows the researcher to concentrate on the research question, not the display methodology or the computer interface.

c. Examples

Recent *visual simulation* projects of the Graphics and Video Laboratory include speed control of autonomous vehicles [Ref. 7], control of autonomous walking machines [Ref. 8], rule-based control of autonomous underwater vehicles [Ref. 9], interactive moving platforms [Ref. 10] and combat vehicle control [Ref. 11]. Each of these projects exceeded the capacity of a single workstation. The speed control and interactive moving platform projects, written entirely in C, used two Silicon Graphics, Inc. IRIS workstations, allowing multiple simultaneous views. The other projects all required a rule-based artificial intelligence component, best programmed in Lisp for ease of modification. Running the Lisp subsystem on the IRIS workstation gave an unacceptably low refresh rate and correspondingly poor realism [Ref. 12]. Placing the
Lisp subsystem on another machine improved the refresh rate of the IRIS workstation used for the graphics display.

2. **Computer System Architecture**

Computer systems can have a distributed or a non-distributed architecture. Distributed architectures have only one characteristic in common, more than one processor used to accomplish the task. Beyond this, many different approaches have been tried [Ref. 13]. Identical processors give a homogeneous architecture. Different processors give a heterogeneous architecture. Either distributed architecture may incorporate shared memory or it may not. The separate processors can be closely or loosely coupled. Communication between processors can be via shared memory, common bus, or some form of communications network. Communication via some combination of the above, such as a file server on a local area network, is also common [Ref. 3]. In the Computer Science Department at the Naval Postgraduate School, a heterogeneous mix of stand-alone workstations, file server supported workstation clusters, and minicomputers communicates via Ethernet.

Programming distributed architectures has inspired creativity. The fundamental problems with distributed programming are the communications between processes and the temporal interaction of the processes. Communicating sequential processes [Ref. 14], distributed processes [Ref. 15], and remote procedure calls [Refs. 2, 16] have all been proposed as primitives to hide message passing from the programmer. Remote procedure calls [Refs. 2, 3] and communicating sequential processes [Ref. 17] have been implemented. However, even today, none of these is generally available as a standard mechanism across varied architectures. We have created simpler (but less general) communication routines for use among heterogeneous, distributed, standalone computers.
Complex projects can require the resources of more than one computer. Graphics portions are best handled by the specialized hardware of a graphics workstation, such as a Silicon Graphics, Inc. IRIS. Artificial intelligence portions are best handled by a Lisp machine, such as a Symbolics* or a Texas Instruments Explorer**. Database requests can be made to a machine with appropriate database software. A general purpose computer, such as the Digital Equipment Corporation VAX***, can be used for additional processing power, file storage, or other administrative support. Providing easy access across such a mix of heterogeneous computers is a large task [Ref. 3]. The simple mechanism described in this work gives communication access between cooperating processes running on diverse hardware. It leaves temporal design to the application developer, while providing the tools for synchronous and asynchronous interaction.

3. Communication

Communications between computers cooperating on a task can be one-to-one, many-to-one, or one-to-many. It can be synchronous or asynchronous. Any, or all, of these can be required for one visual simulation.

One-to-one, or direct connect, communications puts the lowest load on the network when there are few messages to be sent. A single virtual channel between the two processes is required. Each communication between any two processes comprises one message. All messages are known to be intended for the receiving process. These messages can be sent synchronously or asynchronously. Direct connect communication requires one action by the sender and one by the receiver. With more processors,

** Explorer is a trademark of Texas Instruments Incorporated.
*** VAX is a registered trademark of Digital Equipment Corporation.
potential virtual channels grow in number geometrically. For a fully connected network, the virtual channels required can exceed capacity. The potential messages required also grow geometrically in number.

One-to-many, or broadcast, communications puts the lowest load on the sending process. A message is sent to all other processes that are connected to it. It requires one action by the sender, and two actions by each receiver (the reception and a decision on whether the message is intended for that receiver). It also places one to n messages on the network (depending on how the network and the broadcast protocols are designed). It is primarily used in an asynchronous mode, although synchronous protocols could be designed.

Many-to-one communications puts the highest load on the receiving process. It requires two actions by the receiver on every message that is sent by any connected process. It is also a primarily asynchronous method. The receiver portion of a process sees many-to-one whenever broadcast protocols are the only ones used in a visual simulation.

C. ORGANIZATION

The previous sections of this chapter provide background on visual simulation, distributed architectures, and communication paradigms. Chapter II describes the hardware and software environment in the Computer Science Department at the Naval Postgraduate School. The protocols developed are discussed in Chapter III. Chapter IV describes the implementation of the protocols. Chapter V covers the use of these protocols. The performance of the protocols is detailed in Chapter VI. Chapter VII concludes with a discussion of limitations, future extensions and research topics, and summarizes the research conducted. Listings of the program source code for each of the hardware systems are included as Appendices.
II. EXISTING SYSTEM

A. INTRODUCTION

The distributed architecture available in the Naval Postgraduate School Computer Science Department Graphics and Video Laboratory is Ethernet-connected workstations and minicomputers. The workstations include IRIS 2400, 3120, and 4D graphics, Symbolics 36xx* and TI Explorer Lisp, ISI AI, and Sun-3s**. The minicomputers include VAX 11/785 and an ISIV minicomputer complex providing database services. All computers, except the Symbolics and TI, use some version of UNIX*** as the primary operating system.

B. HARDWARE

1. Network

Ethernet connects all the computers in our lab. There is a backbone network and subnetworks for certain groups of computers. Currently there are two subnetworks, one for the ISIV minicomputers and one for the ISI AI workstations. Subnetworks are planned for the IRIS workstations, the Sun Workstations****, and the Symbolics and TI workstations. Figure 2.1 illustrates the network configuration.

* Symbolics 3600, Symbolics 3640, Symbolics 3650, and Symbolics 3675 are trademarks of Symbolics, Inc.

** Sun-3 is a trademark of Sun Microsystems, Inc.

*** UNIX is a trademark of AT&T Bell Laboratories

**** Sun Workstation is a registered trademark of Sun Microsystems, Inc.
Figure 2.1 Network Configuration
All computers support TCP/IP protocols. The Symbolics Lisp machines also use the CHAOS protocol to provide file server services from sym1 to the other Symbolics machines. This logical local area network (LAN) uses the Ethernet backbone for its messages. The Sun file servers also support their diskless nodes over the backbone Ethernet.

2. Workstations

a. Silicon Graphics, Inc. IRIS

Table 2.1 shows the IRIS workstation configurations. All are connected directly to the backbone Ethernet. The proprietary Geometry Engines in each of these workstations allows three dimensional color graphics displays to be generated and updated in real-time. The primary use of these machines is for color graphics.

b. ISI AI

Table 2.2 shows the ISI AI workstation configurations. Only ai8 is connected directly to the backbone Ethernet. The other workstations are connected to it in a subnetwork. These workstations are used primarily for artificial intelligence projects. The ai8 machine provides, as well as a gateway to the backbone Ethernet, file server support for the other workstations. Their high resolution black on white monitors, although bitmapped, have rudimentary graphics capabilities.

C. SOFTWARE

1. UNIX Machines

Two versions of UNIX are commonly used. The machines purporting to use System V*, also incorporate characteristics of 4.2BSD and 4.3BSD. The relevant incorporation is the Berkeley socket mechanism.

a. 4.3BSD

A "pure" 4.3BSD system (4.3 BSD UNIX #11) exists only on unix1. The ISIV minicomputers use 4.2 BSD UNIX Release 3.07, with a multi-backend database system installed [Refs. 18-20]. The ISI AI workstations use IS68K 4.3 BSD UNIX: 4.0D #2.

b. System V

The IRIS 4D systems use UNIX System V-based version 4D1-2.2. The IRIS 2400 and 3120 systems use UNIX System V-based version GL2-W3.6. Both have extensive 4.3BSD extensions. The Sun-3 uses an almost System V version of 4.2BSD UNIX. The currently installed release is 3.4.

2. Lisp Machines

a. Genera

The Symbolics Lisp Machines first used Genera 6.0 software. All machines are now on Genera 7.1.

b. Explorer

The TI Explorer lisp machine first used Explorer version 1.0.2 software. All machines are now on version 3.4 except expl, which is still on version 3.2.

* UNIX System V is a trademark of AT&T Bell Laboratories
D. SUMMARY

The configuration described above is constantly changing. Additional machines are acquired. Older machines receive hardware upgrades. The network is reconfigured. Software releases are updated (especially 4.2BSD UNIX to 4.3BSD UNIX). The fundamental needs for distributed computation in this heterogeneous environment remain.
III. PROTOCOLS

A. INTRODUCTION

Our visual simulation efforts rely on small data transfers to communicate among machines. These small messages are typically commands and changing status indicators. Hence, we optimized our protocols for small messages. Overhead to optimally encode and decode packets was deemed inappropriate. The design criteria for developed protocols were simplicity, ease of use, portability, and efficiency.

B. DIRECT CONNECTION

The client/server paradigm is used for direct connection. The client requests services from the server, so establishing communications is asymmetrical. Once communications are established, however, the protocol used is completely symmetrical. [Ref. 21: p. 17]

1. High-Level Protocol

The variety of data types supported is limited (see Table 3.1). Each message contains exactly one instance of one type of data. All integer or float data is converted to an ASCII character string before it is sent. It is converted back to the proper type after

<table>

</tr>
</tbody>
</table>
reception. While the conversion is unnecessary when communicating between similar architectures, it greatly simplifies the task of communicating between fundamentally different architectures. Knowledge of the other machine's architecture is not required. The inherent portability of this solution outweighs the processing cost.

A message is created with three fields. The type field is a one-character field. It contains the appropriate code from Table 3.1. The length field is a four-character field. It contains an ASCII string from 0001 to 9999. This string gives the length of the data field. The data field is a variable length field containing the ASCII representation of the data element. Figure 3.1 illustrates these fields.

While C programmers are continuously concerned with data types, Lisp programmers are not. The Lisp routines support arrays of characters, single integers, and single floating point numbers. Each of these is an object. Objects, not types (as implied in Table 3.1), are received and sent by lisp applications. The underlying protocol is the same, the application interface is different.

\text{Data} & & & & & & & & & \\
\hline
\end{array}\]

Figure 3.1 Message Format

\(^3\) Chapter 5 discusses applications' use.
2. **Supporting Protocols**

Full-duplex *stream sockets* are used to provide sequenced, reliable connection between machines. The sockets are created in the DARPA Internet\(^4\) domain. The Internet pseudo-protocol is used [Ref. 22]. No out-of-band capability was included. We could not envision a use for it, since our protocol is inherently asynchronous. If a strictly synchronous protocol was used, out-of-band transmission might be necessary to interrupt for an urgent message. In an asynchronous protocol, however, encoding the next message gives the same effect. Processing overhead for encoding is no greater than for continuous monitoring for an out-of-band message. With only a small volume of data transfers expected, no urgent message waits very long.

Two ports, each with its own *stream socket*, are used for each channel between machines. Although full-duplex, the *stream sockets* are used in a simplex mode. The separate sockets are used because two processes cannot be bound to the same socket at the same time. Two separate UNIX processes then monitor the independent send and receive sockets. Blocking sockets are used, avoiding processing overhead for busy-waiting. While non-blocking sockets are available in 4.3BSD [Ref. 21: p. 25], they were not explicitly available in 4.2BSD [Ref. 22]. Operating systems might include 4.2BSD sockets rather than 4.3BSD versions and so the blocking socket mechanism was deemed more portable. Both TCP/IP and the C routines provide buffering.

On the TI Explorer, sockets were also blocking\(^5\). Direct access was made to the TCP methods provided. Lisp *streams* are used for the Symbolics lisp routines. The

---

\(^4\) This is the underlying mechanism of the Defense Data Network (DDN) and was chosen for its wide availability and applicability to Department of Defense problems.

\(^5\) Version 1.0 of the Explorer TCP/IP software uses blocking sockets. Version 2.0 uses non-blocking sockets. There has been no update of this system's TI Explorer lisp routines to version 2.0.
lisp stream mechanism isolates the code from the issues revolving around blocking versus non-blocking sockets.

C. BROADCAST

A broadcast message is sent to all machines on a local Ethernet. Those machines that are waiting for some broadcast message will probably\(^6\) receive it. If a machine on a subnetwork is to get a broadcast message, an application must run on the gateway machine that will rebroadcast on the subnetwork any messages received on the backbone Ethernet. Machines not expecting a broadcast message must nevertheless process it and reject it as inappropriate. The extra load on all machines connected to the Ethernet restricts broadcasting to infrequent occurrences until most of the machines used in simulations\(^7\) are on a private subnetwork.

1. **High-Level Protocol**

   We expect users of the broadcast protocol to mix its use with the use of direct connections. The same data types and messages are supported (see Table 3.1).

2. **Supporting Protocols**

   Full-duplex *datagram sockets* are used to provide connectionless broadcast capability. The sockets are created in the DARPA Internet domain. As with our use of *stream sockets* for the direct connection protocol, we use these full-duplex *datagram sockets* in a simplex mode. We use a sending socket for one-way sending of a broadcast message to all other machines on a single network or subnetwork. We use a receiving socket for one-way receiving from a specific broadcasting machine on the network or

---

\(^6\) Unlike the direct connect protocol, the broadcast protocol does NOT guarantee reception. Trying to provide such a guarantee requires a feedback mechanism so that the sender knows that the machines expected to receive the broadcast did so. This is difficult without resorting to a direct connection or flooding the network with messages.

\(^7\) The IRIS machines and the Lisp machines are the ones principally used for visual simulation.
subnetwork. Direct connection, with its use of guaranteed reliable *stream sockets*, is used for any other communication, including return messages. [Ref. 21: pp. 32-34]

As in the direct connection protocol, independent UNIX processes are bound to the sockets. Since broadcasting is a one-way activity, a sender or receiver only spawns one\(^8\) UNIX process.

D. SUMMARY

By building our high-level protocols on top of DARPA TCP/IP standards, we provide the highest degree of portability possible today. By using full-duplex *stream sockets* and *datagram sockets* in a simplex mode, we do not make full utilization of a socket’s capabilities. However, this concern is outweighed by the increased simplicity and resultant maintainability of the code. The use of ASCII character strings for the messages is simple and makes interconnection with diverse architectures straightforward.

\(^8\) If broadcasting were used exclusively for complete connectivity, each of \(n\) machines would spawn \(n\) processes. If direct connection was used exclusively for complete connectivity, each of \(n\) machines would spawn \(2n-2\) processes.
IV. IMPLEMENTATIONS

A. INTRODUCTION

The first connection was between the IRIS 2400-Turbo and TI Explorer. Then the Symbolics Lisp machines were included. These routines have had extensive use [Refs. 8, 9, 11]. The IRIS functions were updated for the IRIS 4D, coincidentally providing Mex support on the older IRIS machines. Broadcast capability was added for UNIX-based machines. A port to 4.3BSD UNIX (application calls unchanged) was begun.

B. SYSTEM V UNIX

All our System V UNIX-based systems include the socket mechanism first introduced by 4.2BSD. Sockets are a key aspect of all implementations. We expect they will become part of System V or its successors [Ref. 23]. The System V-unique semaphore and shared memory interprocess communication (IPC) capabilities are also used.

1. Silicon Graphics, Inc. IRIS 2400
   a. Sockets

   The socket was introduced in 4.2BSD as the preferred metaphor for IPC. It was easy and efficient to implement and the select mechanism could be used to implement remote procedure calls, if desired [Ref. 23]. System V had no comparable mechanism until version 3 was released with streams. The BSD sockets were included by many vendors, Silicon Graphics, Inc. included\(^9\). While the use of sockets could be

---

\(^9\) The System V version available on the IRIS machines, at the start of the project, was version 2 and so streams were not considered.
replaced with streams, device drivers would have to be written. The advantage of streams is the ability to filter them between streamhead and the actual device driver. These filters, however, reside in the kernel's address space and have the kernel's permissions [Ref. 24]. In our environment, the potential performance increase is not as important as the requirement for simplicity.

The system call for socket creation is `socket`. The system calls supporting socket configuration are `setsockopt`, `bind`, `connect`, and `accept` [Ref. 22]. To simplify their use, these are all repackaged into four high level routines: `connect_server` and `connect_client` for direct connection, `start_broadcast` and `broadcast_receive` for broadcast. These routines are encapsulated in `netV.c`. `netV.c` can be separately linked with any application that needs to make a server/client connection using stream sockets or a broadcasting connection using datagram sockets. Table 4.1 describes the four routines.

**Using the socket number**, a process can transmit data through the socket. In our system, sockets for inter-computer communication are created and used by the `send` and `receive` processes exclusively. The file `netV.c` is not linked with the application at all.

---

10 The `accept` system call is only relevant to stream sockets. The `setsockopt`, `bind`, and `connect` system calls are used with both stream sockets and datagram sockets.

11 In the direct connect protocol, the server process reads from and writes to a remote socket number. The client process reads from and writes to its local socket number. The reason for this is that a server could be connected to different clients (although not in our implementation) at different times. The client, meanwhile, is only going to connect to the one server. In the Internet domain, all necessary routing information, for either server or client, is contained in a `sockaddr` structure and is accessed (transparency) via the socket number.

In the broadcast protocol, both the broadcaster and receiver(s) use their local socket number because they are using connectionless datagram sockets. The routing information is also contained in a `sockaddr` structure.
Table 4.1 SOCKET SUPPORT FUNCTIONS

</tr>
</tbody>
</table>

b. Semaphores

The semaphore mechanism was chosen as the least expensive, in both space and time, for communication between processes. Signals could have been used, but implementation would have been more complex and less reliable. Signal-based communication functions would also have been more difficult for the application programmer to use [Ref. 25: p. 10]. There are two semaphore ids maintained for each connection\textsuperscript{12}. One is used to communicate with the send process; one is used to communicate with the receive process. The two semaphores are both used to signal their process when it is safe to proceed. A send process is permitted to proceed only after the

\textsuperscript{12} Two semaphore ids are required for direct connect protocol connections since both a send and a receive process are spawned. Two semaphore ids are still created for broadcast protocol connections, even though only one process is spawned.
application has requested a write action\textsuperscript{13} on the channel. A receive process is permitted to proceed only after the application has read all data from the shared memory buffer. Neither the send nor the receive process is executing more than absolutely necessary, assuring maximum availability of the local processor to the application.

The system calls supporting semaphores are \textit{semget}, \textit{semop}, and \textit{semctl}. To simplify their use, they are repackaged into three high level routines: \textit{semtran}, \textit{P}, and \textit{V} [Ref. 25: pp. 188-190]. These routines (and a support routine \textit{semcall}) are encapsulated in \texttt{semaphore.c}. It can be separately linked with any application that needs semaphores. Table 4.2 describes the three routines.

c. Shared Memory

A cost barrier to IPC in UNIX is the cost of copying data from one process to the kernel and then from the kernel to another process. Using a \textit{shared memory segment}, as a buffer, minimizes this overhead. To further reduce overhead from system calls, only a single segment is created. An application accesses the entire segment, while a send or receive process accesses only its preassigned section. Figure 4.1 displays the layout. The message area of each section is used for several purposes. It is formatted as

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|}
\hline
Function & Description & Use  \\
\hline
\texttt{semtran} & Creates a semaphore associated with a key. Returns a semaphore id. & \texttt{int semtran( key )}
\texttt{int key;}
\texttt{sid = semtran( key );}  \\
\hline
\texttt{P} & Acquire semaphore & \texttt{void P( sid )}
\texttt{int sid;}  \\
\hline
\texttt{V} & Release semaphore & \texttt{void V( sid )}
\texttt{int sid;}  \\
\hline
\end{tabular}
\caption{SEMAPHORE SUPPORT FUNCTIONS}
\end{table}

\textsuperscript{13} The data must also be valid in the shared memory buffer. All this is transparent to the application, which only issues a write command.

</tbody>
</table>
The system calls supporting shared memory are \textit{shmget}, \textit{shmat}, \textit{shmdt}, and \textit{shmct1} [Ref. 25: pp. 192-198]. To simplify their use, they are repackaged into four high level routines: \textit{sharedsegment}, \textit{dynamicsharedsegment}, \textit{detachsharedsegment}, and \textit{deletesharedsegment}. These routines (and a support routine \textit{attach\_within\_datasegment}) are encapsulated in \texttt{shareseg.c}. It can be separately linked with any application that needs shared memory. Table 4.4 describes the four routines.

The implementation of shared memory on the IRIS 2400 and IRIS 3120 was a surprise. A basic UNIX memory allocation scheme is shown in Figure 4.2. Each process has its own text, data, and stack sections. Neither the relative locations of these sections nor the direction of growth for stack and data sections is specified for UNIX. The shared memory segments are logically part of the data section [Ref. 26: p. 151].

| Table 4.4 \textbf{SHARED MEMORY SUPPORT FUNCTIONS} [Ref. 26: p. 151] |
|-----------------|-----------------|-----------------|
| **Function**      | **Description**            | **Use**                                      |
| \textbf{sharedsegment} | Creates (if not already in existence) a shared memory segment associated with a key. Attaches application to that shared memory segment. Returns a shared memory segment address and id. Does not permit subsequent dynamic memory allocation. | char *\texttt{sharedsegment}( key, nbytes, shmid ) |
| \textbf{dynamicsharedsegment} | Creates (if not already in existence) a shared memory segment associated with a key. Attaches application to that shared memory segment. Returns a shared memory segment address and id. Permits subsequent dynamic memory allocation. | char *\texttt{dynamicsharedsegment}( nummachines, key, nbytes, shmid, freespace ) |
| \textbf{detachsharedsegment}      | Detach shared memory segment from application | void \texttt{detachsharedsegment}( segment ) |
| \textbf{deletesharedsegment}      | Delete shared memory segment | void \texttt{deletesharedsegment}( segment, shmid ) |
Actual implementation is left to the team porting UNIX to the machine. The Silicon Graphics, Inc. implementation attaches a shared memory segment to the first available valid address within the data section. However, the beginning of shared memory delimits the size of all other sections [Ref. 6: pp. 367-370]. Figure 4.3 illustrates this.

---

14 Shared memory segments must begin on a page boundary. This allows easy table-driven access by multiple processes. On the IRIS 2400 and 3120 machines, the Motorola 68000 architecture is used. The pages are 8KBytes.
relationship. While no dynamic memory calls\(^{15}\) are made, the default arrangement works fine. But when dynamic memory allocation—linked lists and `makeobj()` calls are examples—is needed, the technique fails.

To allow dynamic memory allocation, the shared memory segment must be attached at an address beyond the greatest ever required for regular data. Dynamic allocation can then occur without reaching the shared memory segment. Attaching at an unknown address both within the data section and sufficiently beyond existing data to permit dynamic data section growth, can be done at least two ways. First, the data section can be expanded until it is as large as possible, then the shared memory segment

\(^{15}\) Dynamic memory allocation is made with system call `brk` or alternate `sbrk`. Library functions `malloc`, `realloc`, and `calloc` use `brk` and so also do dynamic memory allocation.
can be attached at a valid location just inside this maximum value. While minimizing application programmer effort, this technique requires many system calls to grow the data section. It also has the fatal flaw of limiting the stack section, if the stack section and data section grow into the same unallocated memory. Second, the application can be required to prespecify the maximum amount of dynamic memory allocation it might use.

The solution adopted is adding a `freespace` parameter to the `sharedsegment` function; and renaming it the `dynamicsharedsegment` function. The `sharedsegment` function was retained for backward compatibility. The `freespace` parameter gives the caller the ability to specify the maximum additional memory required for the application. A request for this additional space is made before the shared memory segment is attached. After acquiring (and freeing) the additional space, the next available address is determined and the shared memory segment is attached to the next valid address. We have now established the shared memory segment beyond the specified growth of the application’s data.

When multiple machines are connected together, there must be a separate shared memory buffer for each channel. There is no way to connect a second shared memory segment. The solution adopted is adding a `nummachines` parameter to the `dynamicsharedsegment` function. The `nummachines` parameter requires the application developer to specify, in advance, the maximum number of channels that can be created in the application. The first `dynamicsharedsegment` call establishes a shared memory segment big enough for `nummachines` maximum requested channels. Subsequent `dynamicsharedsegment` calls return the same shared memory id as the first; but return a different address within the segment. Since the application does not directly access these functions, there were no problems caused by this parameter list change.
The shared memory functions are isolated from the application by the machinepath, dynamicmachinepath, dynamicmachinepaths, and deletemachinepath functions\textsuperscript{16}. For the direct connect protocol, each machinepath, dynamicmachinepath, or dynamicmachinepaths call spawns both a send and a receive process. For the broadcast protocol, these calls spawn only a send process (for the broadcaster) or a receive process (for the receiver). In all cases, the spawned processes issue a sharedsegment call to attach to the shared segment earlier created by the spawning function. A command line parameter is passed providing the offset into the shared memory segment that the spawned process is to use. Figure 4.4 illustrates a system with three machines and two channels.

d. Buffering

(1) Direct Connect. When a receive process is quiescent, waiting for the application to read from the shared memory buffer, anything sent to it is buffered by TCP/IP. The buffering provides the reliable delivery promised by a stream socket. The next read command will deliver up to LARGESTREAD bytes into the receive data area of the shared memory buffer. Since the messages are variable length, there cannot be a guarantee that only one message was read\textsuperscript{17}. Multiple messages might be in the shared memory buffer. A partial message might be in the last bytes.

The shared memory buffer management is handled by the various read functions\textsuperscript{18} provided. Each read, requested by the application, is satisfied from the

---

\textsuperscript{16} See Chapter 5, Sections A.1.b(1) and A.1.b(3) for more information on these functions.

\textsuperscript{17} The idea to pad all messages to some arbitrary size was considered and rejected. Whatever size was chosen would always be too small for some character array. If the maximum Ethernet packet size was chosen, an unnecessary network dependence would be introduced. The cost of application buffer management is considered acceptable, especially since it is incurred only on reads.

\textsuperscript{18} See Chapter 5, Section A.1.b(2) for more information on these functions
Figure 4.4 Three-Machine Interconnection
shared memory buffer. Remaining valid data is shifted into the low order positions of the data area. The count of valid bytes, held in the message area, is decremented. The shared memory buffer now appears as it would have, if it had only received the remaining data and not the first message at all. As long as only entire messages are received (one or more at a time), this works well. When the TCP/IP buffer has more data than the data area can take at one time, however, the receive process deposits LARGESTREAD bytes in the shared memory data area. It is highly unlikely that this will be on a message boundary.

A socket read overwrites all data in the data area. A partial data reception must be stored and concatenated with bytes from the next socket read to get a complete message. The protocol area was introduced to retain the protocol information\(^1\) required to decipher the variable length messages. The count of already received bytes of a message is held here between socket reads. A message's protocol information is stored here, too. Protocol information is built up until complete (covering the possibility that the break is in the protocol information itself). It is then maintained until the entire message is received and read by the application. The buffering works with data areas as small as four bytes\(^2\).

(2) Broadcast. The datagram socket used by the broadcast protocol preserves message boundaries. Each recvfrom call to a socket returns only one message. This message must be no longer than LARGESTREAD bytes. The shared memory buffer management routines are not needed.

---

\(^1\) See Chapter 3, Section B.1 for a description of the protocol

\(^2\) LARGESTREAD must be specified in multiples of four bytes. The smallest possible data area is therefore four bytes.
TCP/IP keeps unread messages on a queue. This queue may not be in sending sequence. If the queue buffer becomes full, subsequent messages are lost [Ref. 21: p. 8-8]. The sending buffer can easily be filled if many messages are broadcast in a short period of time. Each broadcast message must be processed by every host on the Ethernet. Only then can the next be sent. No access for manipulation of the TCP/IP sending buffer is provided because its size is normally specified during system generation and is not easily manipulated by an application program.

2. Silicon Graphics, Inc. IRIS 3120

There are no required changes to the IRIS 2400-Turbo code. The Makefile must be changed to remove the -Zf compile flag, since there is no floating point accelerator board in this machine.

3. Silicon Graphics, Inc. IRIS 4D

The IRIS 4D required programming changes only to the shared memory module, shareseg.c. The path name for user directories is also different. Changes were necessary to the Makefile because the /usr/include directory structure changed.

The IRIS 4D is based on the MIPS RISC architecture. The UNIX implementation was done differently than that for the Motorola 68020. Shared memory segments are not attached to addresses within the data section, as illustrated in Figure 4.5. They are attached at a much higher address, yet accessing them does not result in a segmentation violation. This is a more robust technique that obviates any manipulation of attachment addresses. Multiple shared memory segments are easily attached, using default system calls. The sharedsegment call suffices, even when dynamic memory allocation is needed. To maintain backward compatibility for application code, dynamicshtaredsegment calls sharedsegment, ignoring the freespace parameter, when compiled on an IRIS 4D, and calls attach_within_datasegment when compiled on an older IRIS machine.
C. 4.3BSD UNIX

The netV.c file functions properly on a 4.3BSD machine that is connected to only one network. The start_broadcast function does not properly handle multiple networks. The other functions work correctly, even when the machine is connected to multiple networks.

All other functions depend upon semaphores and shared memory for communication between the spawned processes and the main application. Stream sockets\textsuperscript{21} could be used to provide the IPC between these processes under 4.3BSD. The

\footnote{\textsuperscript{21} Unidirectional stream sockets are equivalent to pipes.}
three channels used will have to be multiplexed into one, but the implementation is otherwise straightforward.

D. LISP MACHINES

The communication code is a flavor to be mixed with the application [Ref. 11]. The Explorer software is syntactically equivalent to Genera 6 on the Symbolics. With a simple change in the sequence of method and flavor names, the Genera 7 code runs on the TI Explorer. The older flavor, originally developed for the Explorer, is also presented to illustrate working directly with TCP/IP instead of using a stream.

1. Texas Instruments Explorer I

This older flavor works with Release 1.0 of the Explorer TCP/IP software. It will not work with Release 2.0 as the implementation was changed from blocking to non-blocking [Ref. 27].

Messages to the flavors in the ip package are made together with messages to the tcp flavors. Network-independent addressing is not used. Table 4.5 describes the addressing schemes possible [Ref. 28: pp. 4-2—4-3]. Class C addressing is used by the Computer Science Department. Figure 4.6 shows the simple encapsulation of the addresses for *iris1*, *iris2*, and *iris3*. Extension to include other machines is easy.

        (t (setq *dest-address* *iris2-address*)))

Figure 4.6 Encapsulation of IRIS Addresses

A port is acquired by using the :get-port method of the tcp-handler flavor. Here, shown in Figure 4.7, we use the global instance, *tcp-handler* to create specific instances of the Transmission Control Block (TCB) for each of the two ports. Only the client side of the server/client paradigm has been implemented. The client is created by using the :active mode argument to the :open method of the tcp-port flavor. Both the sending and receiving ports are full duplex, but are only used in a simplex mode. Figure 4.8 shows the creation of the sending port [Ref. 28: pp. 4-12—4-18].

The three fields in a message are sent and received separately. Each field is then treated as a separate object. Figure 4.9 illustrates sending a message. For all fields, the urgent argument is specified as nil. The push argument is specified as nil until the

                         t nil))

Figure 4.9 Sending a Message

data buffer is sent, when it is specified as t. The entire message is thus sent as a unit to the other machine.

2. Symbolics 36xx

Genera 7 syntactic conventions are followed. The principle difference with Genera 6 conventions is in the defmethod function. In Genera 6 (and the TI Explorer), the method name follows the flavor name. In Genera 7, the method name precedes the
flavor name. Figure 4.10 shows the difference. It also shows the other main difference with the earlier code, that streams are used. The use of streams improves portability and eliminates the need for the :reuse-iris method\(^{24}\). It may be slightly slower, but any difference has been unnoticeable.

Another change was to remove the dependence on hard-coded addresses. The method :init-destination-host was added to the conversation-with-iris flavor (see Figure 4.11). By using the net:parse-host function, the application need only know the name of another machine. As network tables are updated, no change to the application code is necessary unless a different machine is desired.

\(^{24}\) The :reuse-iris method is retained for backward compatibility.
E. SUMMARY

For UNIX-based machines, generic routines are developed for semaphore use, shared memory use, and socket use. The socket routines use both *stream sockets* and *datagram sockets* in a simplex mode to provide directly connected client/servers and unconnected broadcasting communications. IRIS 2400, 3120, and 4D systems are fully supported. 4.3BSD systems are supported with mid-level socket calls only.

For Lisp machines, stream-based functions are available for direct connection as clients only. These functions are available directly if using Genera 7 syntax and with minor modification if using Genera 6 syntax.
V. USE BY APPLICATIONS

A. INTRODUCTION

The application using either direct connect or broadcast protocol is not concerned with system-level implementation details. Almost all aspects of shared memory, semaphore, and socket use are hidden. The number of other machines to be connected to, the use of dynamic memory allocation, and the names of the other machines are all that concern the application in setting up a connection. The synchronization, or lack thereof, in communication between machines is a design decision, not a protocol decision.

B. DIRECT CONNECT

A UNIX-based machine can be either a server, waiting for a client to call and establish a connection, or the client. A Lisp machine is always a client.

1. UNIX-Based Machines

The functions provided for UNIX-based machines are all written in C. They must be linked into the application program using them. Figure 5.1 is an example make file for creation of an application program on an IRIS system.

There are two independent processes, send and receive, that are spawned to create the sockets and monitor them. They are made separately with the makefile\textsuperscript{25} contained in their subdirectory.

a. Application Setup

The server process must be started first. The application can set up the communications paths as part of initialization, or it can do so only in response to a
specific operator command. In either case, there will be two messages returned to the terminal for each direct connection setup. Figure 5.2 illustrates a normal, single connection, response. Since the receive and send processes that provide the messages are independent, the two lines shown may be jumbled. A variety of errors can occur at this point. Table 5.1 gives the most common error messages, their cause, and solution.

Table 5.1 SERVER ERROR RESPONSES
The client process must not attempt connection until after the server is properly running (the messages in Figure 5.2 have been received). The application can set up the communications paths as part of initialization, or it can do so only in response to a specific operator command. When client communications setup is part of the initialization, care must be taken to wait for a ready server before starting the client. In either case, there will be two messages returned to the terminal for each direct connection setup. Figure 5.3 illustrates a normal, single connection, response. Since the receive and send processes that provide the messages are independent, the two lines shown may be jumbled. A variety of errors can occur at this point. Table 5.2 gives the most common error messages, their cause, and solution.

b. Coding Practices

(1) Connection. Making a connection requires two acts. The first is to set aside space for the data required. Figure 5.4 shows this code when local declaration is used. The Machine structure can also be declared globally. The second is to request the connection with a machinepath, dynamicmachinepath, or dynamicmachinepaths call. Table 5.3 compares the three types of call, while Figure 5.5 gives a server example for dynamicmachinepath. A description of the parameters used is in Appendix A, Section 2.a.

For flexibility, there is often a requirement for command line specification of the machine to be connected to. For ease of use, there is often a

requirement for a default specification. Figure 5.6 illustrates one way to accomplish this for a client. This example does not require that the network alias be defined to the system as it uses the complete address. The user, however, only enters the alias.

(2) Program Use. The simplest high-level communication paradigm is reading from and writing to the other machine. It closely parallels handling files and terminals in C. It was chosen for these reasons.

Twelve high-level functions are available. Four provide status information, four write to other_machine, and four read from other_machine. Table 5.4 describes these functions. The parameters used by these calls are described in Appendix A, Sections 1.a and 9.a.

Figure 5.6 Command Line Direction for Connection

There is a variety of ways to use these functions. Figure 5.7 illustrates a typical scenario. This code is from the display station of a two-workstation driver simulation. The display station provides its status (that of the "world") on each pass through its graphical display loop. The control station must read that status on each pass, to update the vehicle position on its track diagram. On each pass, the display station checks to see if any commands have been received. This is an asynchronous communication, as the display station continues with or without a control station.
command. The asynchronous reads are guarded by a `receiver_has_data` call that detects arrival of a message. Other `receiver_has_data` calls are used to "busy wait" for the next message. In practice, it has not been necessary to include any but the first "busy wait" `receiver_has_data` call. TCP/IP buffers messages when they are not immediately read. It then blocks them into the largest grouping possible and delivers them when the next read occurs. The LARGESTREAD defined constant in *shared.h* determines this maximum grouping. The first message is read by `receive`. The socket is then ignored until the application reads the data. During this time, the other messages have all been sent and buffered by TCP/IP. There is a slight delay between the time the first message is read and the block containing all the rest is read. Thus the necessity for the first "busy wait" `receiver_has_data` call. The other "busy wait" `receiver_has_data` calls are simply for robustness.

The "busy wait" `sender_is_free` call determines if something has happened to the other machine or Ethernet. The first write will always succeed, as it goes to a buffer. If there is a communications problem, TCP/IP will not accept it and the

    write_integer(&cardriver, &vehicle.situation.lightcolor);
}

} /* while loop */

} /* main */

Figure 5.7  Synchronous Write / Asynchronous Read
sender_is_free call will return FALSE. This often occurs when there is a delay by the client in connecting to the server (the display station here). If there is a good connection, TCP/IP will accept and buffer all input. No other "busy wait" calls are needed. The other side of the communication is shown in Figure 5.8.

(3) Disconnection. Termination, with a deletemachinepath call for each path opened, is mandatory. If not performed, the sockets (and shared memory segment on System V UNIX machines) will not be returned to the system. Problems may then occur on the next run. Figure 5.9 is an example termination when multiple paths have been opened [Ref. 11].

2. Lisp Machines

All necessary functions are contained in a single file. This file must be loaded before use. Figure 5.10 is an example. A Lisp machine is always a client and is started second. Figure 5.11 illustrates the message returned with a successful connection. Unsuccessful connections “hang” and return nothing.

a. Connection

The address of the server and the ports it is using must be specified. Figure 5.12 shows the ports specified as part of the loaded file. When using the older TI Explorer functions, the addresses are specified in the same way (see Figure 4.5) and then the machine desired is requested by number (shown in Figure 5.13). When using the stream-based functions, the addresses are not specified by the user at all. The network tables are accessed, by host name, through the select-host function provided (shown in Figure 5.14). Once the instance of conversation-with-iris flavor has been completed

51
with port numbers and host addresses, the connection is established with the method
:start-iris, see Figure 5.13.

b. Program Use

The method :get-iris returns with the object sent by one message. The
method (:put-iris object) sends the object as one message. Figure 5.15 illustrates both.
Note how methods are added to flavor conversation-with-iris to simplify the
application interface even further. [Ref. 11]

c. Disconnection

Disconnection is accomplished with the method :stop-iris, shown in
Figure 5.16.

C. BROADCAST

Only UNIX-based machines support our broadcast protocol at this time. It is a
unidirectional protocol, but nothing prevents the establishment of two unidirectional
channels in opposite directions. Using two broadcast channels to emulate a direct
connect channel, however, loads all other machines on the network by requiring every
other machine to process each message. It is also less reliable. Broadcasting is good for
sending status information to many other machines, as long as those machines can
tolerate missing reports.

1. Similarities With Direct Connect Protocol Use

Using the broadcast protocol is similar to using the direct connect protocol.
The same functions are used in the same way. Each connection must set aside space as
::: definitions:

    )
  )
)

Figure 5.15  Application Communication in Lisp

in Figure 5.4. The same criteria for using a specific machinepath call apply (see Table 5.3). The same communications functions are available as in Table 5.4. Each connection must be terminated as in Figure 5.9.
2. Differences With Direct Connect Protocol Use

a. Application Setup

The broadcast protocol is not directly modeled as a server/client relationship. The broadcaster broadcasts to whomever is prepared to receive. The receiver must be ready and so must be started first. Since the broadcaster is more similar to the server in a server/client model, this connection order seems exactly backward. No error will result if the broadcaster starts first, messages will simply not be received. The receiver message is shown in Figure 5.17. The broadcaster message is shown in Figure 5.18. When a direct connect channel is also required between the same two machines, achieving proper startup order is easy. Establish the direct connect channel first, then the soon-to-be broadcasting process sends a message telling the receiver to start up. Once started, the receiver process sends a message permitting the broadcaster to start.

**Figure 5.16** Termination of Communications in Lisp

```lisp
(if (y-or-n-p "stop iris connection ?")
  (send *battle* :stop-iris))
```

**Figure 5.17** Normal Receiver Response

**Figure 5.18** Normal Broadcaster Response
b. Coding Practices

The parameters to the *machinepath* family of functions are used differently for the broadcast protocol. All are required to be present, but some are ignored (see Table 5.5). Since a broadcast channel is unidirectional, the *receive_type* application calls are meaningless to the broadcaster (the *receiver_has_data* call always returns false). The *send_type* application calls are meaningless to the receiver (the *sender_is_free* call always returns false).

D. SUMMARY

Using the same functions, an application can either broadcast or directly connect to another machine. The same steps of setup, connection, use, and termination are common to both protocols. Care must be taken in the timing of the two (or more) machines setup. After that, an application merely reads or writes data.

VI. PERFORMANCE

A. INTRODUCTION

We look at the size of packets from our protocols. We also look at the effect of real applications on the network. We try to do this for both direct connect and broadcast protocols. However, no application making good use of broadcast protocols exists. Hence, we used a direct connect test application and replaced the channel with two broadcast channels.

B. DATA COLLECTION

The LANalyzer* EX 5500 network analyzer was used to gather Ethernet statistics. Version 2.0 of the software was used. The LANalyzer 5500 is a COMPAQ PORTABLE II** with a coprocessor board installed. The coprocessor board has an Intel 80286 CPU, an Intel 82586 LAN coprocessor, and two MBytes of memory. It performs packet collection, packet filtering, and network statistics calculation. The COMPAQ PORTABLE II processor handles user software control, screen updating and disk I/O. [Ref. 29]

Samples were taken while direct connect applications were running on iris2 and iris3. To compare direct connect protocol with the broadcast protocol, test programs were used28. Table 6.1 summarizes the information collected. These programs send a character string, an integer, and a floating point number in a rotating sequence. The messages are either sent to the machine specified on the command line or are broadcast to all machines on the local network but only received from the machine specified.

The *visual simulation* application measured was a modified version of the driving simulator [Ref. 7]. Table 6.2 summarizes the information collected. This data was taken during the day. The application’s communication code is shown in Figure 5.7 and Figure 5.8. One trip around the track took approximately five minutes. Seven messages are sent every cycle to report status. Four messages are sent in the opposite direction, as required, to control the car. One circuit was driven, on autopilot, for each test run. There were about 500 cycles per test. Approximately 3600 messages were generated per test. The number of packets sent was less than half of this. The apparent discrepancy exists for two reasons. First, each packet sent also generates an

*At night, with less competition for network resources, the results were similar.*
acknowledgement packet in return. By acknowledging each packet, the *stream socket* guarantee of delivery and proper sequence is met. Second, after the first packet (containing the first message) is received, the remaining three or six messages are immediately sent. The receiving process has often not yet handled the first one. The remaining messages are combined into one and all are read as one block. This reduces the interchange to a typical total of four packets per cycle, two with data and two for acknowledgement. Similarly, four packets are usually generated whenever the navigator process issues a command sequence to the car.

An evaluation of a five-workstation application [Ref. 11] was also made. This application used three Symbolics (*sym1*, *sym3*, and *sym4*), *expl*, and *iris2* to perform its tasks. Statistics were similar to the other application, but the Symbolics *irisflavor.lisp* exhibited some problem behavior. It sent three packets for every message. The first packet contained the *type field* only. The second packet contained both the *type field* and the *length field*. The third contained the entire message. If a second message immediately followed the first, three more packets were sent, each adding one field to the previous packet. Only one acknowledgement was received, as all packets in a group had the same identification number.

C. DISCUSSION

Attempting to use broadcast protocol with the simple test programs failed. One problem encountered was overflow of the sending buffer within the TCP/IP layers. The rapidity of attempted transmission was the cause. Higher network loading exacerbated the problem. When the test application was slowed down with *printf* calls (and the output redirected into a file) the buffer could keep up with sending requests. 

---

30 See Appendix C
broadcast protocol within a graphics display loop should pose no problems unless numerous data elements are transmitted at one time.

Without acknowledgement packets, broadcasting put fewer packets on the network than did the direct connect protocol. When overall load was heavy, some were lost. This poses a serious problem for visual simulation applications. Without an elaborate application-level protocol, the receiving process will never know what was intended to be sent. Since only one data object is transmitted at a time, labeling the data objects is difficult. All that is available is to alternately send different types and, after checking the type received, make a determination of the likely intent of the sending process. If a block of data, containing different types, could be sent as a single message, the decoding problem would become one of simply sequence checking. Missing status packets can be safely ignored in many situations. At most, a simple averaging algorithm can smooth any discontinuities caused by a missing packet. Timestamping, with a virtual timestamp, of each packet would eliminate the averaging requirement.

The Symbolics stream version is much less efficient, in terms of network utilization, than is the Explorer's. It still functions correctly, with no noticeable delay. As the amount of data to transmit increases, the Symbolics flavor will eventually have noticeable performance degradation.

The interconnection of five machines loads the network only slightly more than does that of two. The limitation will be from the process swap overhead, not the network.

D. SUMMARY

The direct connect protocol sends fewer packets than messages. Half of the packets sent are acknowledgements. These acknowledgements provide the reliability of the direct connect protocol. The broadcast protocol sends one packet for each message. These packets tend to be smaller than those for the direct connect protocol. Until a
mechanism exists to bundle several messages into one broadcast packet, the broadcast protocol is of small value.
VII. CONCLUSIONS AND RECOMMENDATIONS

A. LIMITATIONS

There are two primary limitations. First, the Lisp and C functions differ at the user level. This was done to allow each to be used readily by programmers "thinking" in their respective language. We have found this to be confusing to students who are inexperienced in both languages. Second, there is no simple means to transmit a block of data or an entire file. Each data element, unless it is part of an array of characters, must be sent separately. This was done to "hit a middle ground" between a complex facility—`printf` function—and low-level system calls. As long as only the direct connect protocol existed, this was only an annoyance. As discussed in Chapter 6, this is a critically limiting factor for the broadcast protocol.

The port to BSD UNIX systems without shared memory and semaphores was not completed. The socket handling aspects are portable, but the shared memory aspects are interwoven throughout the system. The difficult part of the porting will be designing the message-passing protocol for the pipe between the application and the `send` and `receive` processes, as discussed in Chapter 4. Other specific limitations include:

- no broadcast capability for Lisp machines
- no server capability for Lisp machines
- limited communication error handling—no signals are sent from the `send` or `receive` processes to the application process if they encounter problems
- limited read/write error handling—a read or write of the wrong type will be attempted and usually produce garbage
- no out-of-band capability
- Symbolics `iris-flavor.lisp` creates three packets per message
B. FUTURE RESEARCH AREAS

Implementation of the missing structure data type is one key area in which more work could be done. The most straight-forward solution to this would be to add messages to the send section of the shared memory array without signalling the send process to send it until the entire block was ready. Such a solution eliminates any need to change the receiving functions at the cost of either an additional sending function or an additional parameter to the existing send functions. The additional send function would be a push function and the existing send functions would be modified to never signal the send process to send. That would be left to the new push function. Adding a parameter to each send function would allow any send function to push. While in some respects simpler, changes to any application sending a block of data would have to carefully monitor which send function actually is pushing.

Creation of a Lisp flavor that mimics the UNIX functions would prove useful to C programmers who find a need for Lisp modules in their visual simulation. Adding server and broadcast capabilities would increase the applicability of the protocols to future visual simulation projects. Functions to break complex Lisp objects into simple ones and then combine these into a single message are necessary for the broadcast protocol. The Symbolics version should be corrected to send a packet only at message boundaries.

C. SUMMARY AND CONCLUSION

The routines described herein have already proved useful to researchers at the Naval Postgraduate School. With Ethernet loading never exceeding one percent, these routines are efficient enough to use without concern. With the additions mentioned above, the goal of an easy-to-use yet powerful system will be reached.
APPENDIX A - IRIS MODULE DESCRIPTIONS

1. io_single.c

   a. Calling Protocols

      This module contains functions that are intended for the application’s use and functions that are used exclusively by them. The parameters for externally accessible functions are described below.

      i. number_received

         number_received( instructure )

         Machine *instructure; /* includes char *instructure.segment a pointer to the shared segment */

      ii. read_character

         read_character(instructure,character_out)

         Machine *instructure; /* includes char *instructure.segment a pointer to the shared segment */

         char *character_out; /* pointer to output character */

      iii. read_characters

         read_characters(instructure,outarray,arraysize)

         Machine *instructure; /* includes char *instructure.segment a pointer to the shared segment */

         char outarray[]; /* output character buffer */

         int arraysize; /* the number of characters to be returned */

      iv. read_float

         read_float(instructure,float_out)

         Machine *instructure; /* includes char *instructure.segment a pointer to the shared segment */

         float *float_out; /* pointer to output float */

      v. read_integer

         read_integer(instructure,integer_out)

         Machine *instructure; /* includes char *instructure.segment a pointer to the shared segment */

         int *integer_out; /* pointer to output integer */
io_single.c

vi. received_type

```
char received_type(instructure)
```

```
Machine *instructure; /* includes
char *instructure.segment a pointer to the shared segment */
```

vii. write_character

```
write_character(instructure,character_in)
```

```
Machine *instructure; /* includes
char *instructure.segment a pointer to the shared segment
int instructure.sendsem the semaphore to the sender */
char *character_in; /* pointer to input character */
```

viii. write_characters

```
write_characters(instructure,inarray,arraysize)
```

```
Machine *instructure; /* includes
char *instructure.segment a pointer to the shared segment
int instructure.sendsem the semaphore to the sender */
char *inarray; /* input character buffer */
long arraysize; /* the number of characters input */
```

ix. write_float

```
write_float(instructure,float_in)
```

```
Machine *instructure; /* includes
char *instructure.segment a pointer to the shared segment
int instructure.sendsem the semaphore to the sender */
float *float_in; /* pointer to input float */
```

x. write_integer

```
write_integer(instructure,integer_in)
```

```
Machine *instructure; /* includes
char *instructure.segment a pointer to the shared segment
int instructure.sendsem the semaphore to the sender */
int *integer_in; /* pointer to input integer */
```
io_single.c

b. Code and Description

```
TITLE: Inter-Computer Communication Package

MODULE: io_single.c

VERSION: 3.0

DATE: 15 December 1987

AUTHOR: Theodore H. Barrow

HISTORY:

VERSION: 1.0

DATE: 27 May 1987

AUTHOR: Theodore H. Barrow

DESC.: Originally part of support.c. Contains the documented read and write calls for use by the application programmer.

VERSION: 2.0

DATE: 21 October 1987

AUTHOR: Theodore H. Barrow

DESC.: Modified read routines to use a global array to manage the possibility of a partial message receipt.

VERSION: 3.0

DATE: 15 December 1987

AUTHOR: Theodore H. Barrow

DESC.: Modified read routines to use part of a buffer set instead of the global array to manage the reception of a partial message.

a. Calling Protocols

All functions in this module are meant to be accessible by the application. These functions set up and tear down the communications path between two machines.

i. deletemachinemachinepath

deletemachinemachinepath(instructure)

Machine *instructure; /* structure to hold segment and semaphore info:
    char *instructure.segment -- returned ptr to the shared segment.
    int instructure.shmid -- returned system generated shared mem id
    int instructure.sendsem -- the returned send semaphore.
    int instructure.receivesem -- the returned receive semaphore.

    We base it on the send portnumber.
    We base it on the receive portnumber.

*/

ii. machinemachinepath

machinemachinepath(segmentnum, mname, sendportnum, receiveportnum, server, instructure)

long segmentnum; /* the key to use for the created shared segment */
char mname[]; /* machinename character string */
long sendportnum, receiveportnum; /* send and receive port numbers */
char server[]; /* this character string is either "client" or "server".
    It indicates whether the sender/receiver should open
    up as either a client or server. The first guy open
    must be the server.

Machine *instructure; /* structure to hold segment and semaphore info:
    char *instructure.segment -- returned ptr to the shared segment.
    int instructure.shmid -- returned system generated shared mem id
    int instructure.sendsem -- the returned send semaphore.
    int instructure.receivesem -- the returned receive semaphore.

    We base it on the send portnumber.
    We base it on the receive portnumber.

*/

iii. dynamicmachinemachinepath

dynamicmachinemachinepath(segmentnum, mname, sendportnum, receiveportnum, server, instructure, freespace)

long segmentnum; /* the key to use for the created shared segment */
char mname[]; /* machinename character string */
long sendportnum, receiveportnum; /* send and receive port numbers */
char server[]; /* this character string is either "client" or "server".
    It indicates whether the sender/receiver should open
    up as either a client or server. The first guy open
    must be the server.

*/

Machine *instructure; /* structure to hold segment and semaphore info:
    char *instructure.segment -- returned ptr to the shared segment.
    int instructure.shmid -- returned system generated shared mem id
    int instructure.sendsem -- the returned send semaphore.
    int instructure.receivesem -- the returned receive semaphore.

    We base it on the send portnumber.
    We base it on the receive portnumber.

*/

int freespace; /* amount of freespace desired for dynamic memory allocation
    after this routine has been called. */
### mpath.c

#### iv. dynamicmachinepaths

dynamicmachinepaths(nummachines, segmentnum, mname, sendportnum, receiveportnum, server, instructure, freespace)

```c
int nummachines; /* the maximum number of other machines to be attached */
long segmentnum;  /* the key to use for the created shared segment */
char mname[];    /* machine name character string */
long sendportnum, receiveportnum; /* send and receive port numbers */
char server[];   /* this character string is either "client" or "server". It indicates whether the sender/receiver should open up as either a client or server. The first guy open must be the server. */
int instructure; /* structure to hold segment and semaphore info: */
    char *instructure.segment -- returned ptr to the shared segment.
    int instructure.shmid -- returned system generated shared mem id
    int instructure.sendsem -- the returned send semaphore.
        We base it on the send portnumber.
    int instructure.receivesem -- the returned receive semaphore.
        We base it on the receive portnumber.
int freespace;    /* amount of freespace desired for dynamic memory allocation after this routine has been called. */
```

#### b. Code and Description

---

**TITLE**: Inter-Computer Communication Package  
**MODULE**: mpath.c  
**VERSION**: 5.0  
**DATE**: 31 May 1988  
**AUTHOR**: Theodore H. Barrow

---

**HISTORY:**  
**VERSION**: 1.0  
**DATE**: 6 February 1987  
**AUTHOR**: Michael J. Zyda  
**DESC.**: Contains routines machinepath and deletemachinepath for link creation/removal at a high level of abstraction.  
**VERSION**: 2.0  
**DATE**: 27 May 1987  
**AUTHOR**: Theodore H. Barrow  
**DESC.**: Converted to use a structure for ease of use.  
**VERSION**: 3.0  
**DATE**: 21 October 1987  
**AUTHOR**: Theodore H. Barrow  
**DESC.**: Added function dynamicmachinepath to allow dynamic memory
mpath.c

allocation after communications link established.

VERSION: 4.0
DATE: 15 December 1987
AUTHOR: Theodore H. Barrow
DESC.: Added function dynamicmachinepaths to allow use with multiple links. Modified all creation routines to place sequence numbers at end of command line for send and receive processes.

VERSION: 5.0
DATE: 31 May 1988
AUTHOR: Theodore H. Barrow
DESC.: Added broadcast and receive capability - one process spawned

RECORD OF CHANGES

Version  Date  Author  Change Description  Affected  Req'd

Version: 4.8  May 31  Theodore H. Barrow
Added broadcast and receive capability - one process spawned.
#include "shared.h" /* my special defines */
#include <gl.h>

deletemachinepath(instructure)

**netV.c**

* **AUTHOR**: Theodore H. Barrow

* **DESC.**: Added `start_broadcast()` and `broadcast_receive()` to provide datagram sockets for broadcast use. These sockets use the default Internet broadcast addressing.

7. shared.h

a. Calling Protocols

This module has all the predefined constants and type definitions. It must be included in the application.
shared.h

b. Code and Description

******************************************************************************
TITLE : Inter-Computer Communication Package
MODULE : shared.h
VERSION: 4.0
DATE : 15 December 1987
AUTHOR : Theodore H. Barrow

HISTORY:

VERSION: 1.0
DATE : 6 February 1987
AUTHOR : Michael J. Zyda
DESC. : Contains all defines and special constants for shared
memory socket system.

VERSION: 2.0
DATE : 27 May 1987
AUTHOR : Theodore H. Barrow
DESC. : Added a typedef of structure for use by various routines.
Added message types for high level read/write protocol.

VERSION: 3.0
DATE : 21 October 1987
AUTHOR : Theodore H. Barrow
DESC. : Changed dependencies of buffer calculation constants so that
only one need change. Added additional message types.

VERSION: 4.0
DATE : 15 December 1987
AUTHOR : Theodore H. Barrow
DESC. : Added field to buffer set so that each link would have its
own area to handle partial receipt of messages.

8. shareseg.c

a. Calling Protocols

This module contains the low-level shared-memory calls. No functions in this module are intended for application programs.

b. Code and Description

```c
TITLE : Inter-Computer Communication Package

MODULE : shareseg.c

VERSION: 3.1

DATE : 24 February 1988

AUTHOR : Theodore H. Barrow

HISTORY:

VERSION: 1.0

DATE : 6 February 1987

AUTHOR : Michael J. Zyda

DESC. : Contains routines to manage shared memory segment. Creation
        attachment, detachment and deletion are all covered.

VERSION: 2.0

DATE : 21 October 1987

AUTHOR : Theodore H. Barrow

DESC. : Added function dynamicsharedsegment to allow dynamic memory
        allocation after communications link established.

VERSION: 3.0

DATE : 15 December 1987

AUTHOR : Theodore H. Barrow

DESC. : Modified function dynamicsharedsegment for use with multiple
        links. First call does shared segment creation. Subsequent
        calls return address for the next buffer set.

9. **support.c**

a. **Calling Protocols**

This module contains functions that are intended for the application’s use and functions that are used exclusively by other routines. The parameters for externally accessible functions are described below.

i. **receiver_has_data**

```c
int receiver_has_data(instructure)

Machine *instructure; /* includes
    char *instructure.segment a pointer to the shared segment */
```

ii. **sender_is-free**

```c
int sender_is_free(instructure)

Machine *instructure; /* includes
    char *instructure.segment a pointer to the shared segment */
```
support.c

6. **testshare.c**

   a. **Calling Protocols**

      This is a stand-alone utility. It will print current parameters for all active
      shared memory segments. By command line argument, selective segments can be
      printed.

   b. **Code and Description**

      ```
