Thermal Conductivity and Viscosity via Phonon-Phonon, Phonon-Roton and Roton-Roton Scatterings in Thin 4He Films

Chung-In Um, Chul-Won Jun, Woo-Hyung Kahng and Thomas F. George

The coefficients of the thermal conductivity ($\kappa$) and first viscosity ($\eta_r$) in thin helium films are evaluated explicitly as a function of temperature via phonon-phonon, phonon-roton and roton-roton scatterings. Above about 0.8 K, phonon-roton scatterings and five-phonon processes are the main contributors to both coefficients. Below about 0.8 K both coefficients increase exponentially with decreasing temperature. At temperatures below 0.3 K, $\kappa_{\text{ph}}$ has a $T^{-5}$ dependence, while $\eta_{r,\text{ph}}$ shows exponential and $T^{-2}$ dependences. In the case of $\eta_{r,\text{rot}}$, the former is due to phonon-roton scattering and the latter originates from three-phonon processes. The coefficient $\kappa$ from roton-roton scattering varies as $T^{-1}$, and the roton part $\eta_r$ of the first viscosity is independent of temperature.
Thermal conductivity and viscosity via phonon-phonon, phonon-roton and roton-roton scatterings in thin $^4$He films

I. Introduction

Since the works of Landau and Khalatnikov on kinetic phenomena\(^1\) in superfluid helium, there has been continuous interest in thermal conductivity and viscosity for bulk liquid \(^4\)He and \(^3\)He at low momenta and at low temperatures.\(^2\) Recently Kirkpatrick and Dorfman\(^3\) obtained transport coefficients for very low temperatures (\(n\alpha^2 \gg 1\)) and for moderately low temperatures (\(n\alpha^2 \ll 1\)) on the basis of their kinetic equations for a dilute superfluid, where \(n\), \(\alpha\) and \(\lambda\) represent the number density, the s-wave scattering length and the thermal wave length, respectively.

In the case of thin helium films, the dissipation of superfluid flow and thermal conductance have been investigated by many authors.\(^4\) Ambegaokar et al.\(^5\) have predicted that the effective thermal conductance in thin helium films has exponential dependence on temperature for \(T < T_C\) and diverges exponentially for \(T - T_C^+\), where \(T_C\) is the thermodynamic Kosterlitz-Thouless temperature. More recently the depairing\(^6\) and the depinning\(^7\) vortices which give the power law and the exponential dependence of thermal conductance have been investigated experimentally by Gasparini et al.\(^8\), who confirmed an exponential dependence rather than the power law for \(T < T_C\). However, there is much less information about thermal conductivity and viscosity in thin helium films at low momenta and at very low and moderately low temperatures. What is more important is that a wrong normal dispersion relation was used in Landau and Khalatnikov's well-known results,\(^1\) while the correct dispersion is anomalous dispersion.\(^9\) For this reason and in view of recent experimental development on helium films, we present in this paper new results on the thermal conductivity and viscosity of superfluid helium films through the theory of kinetic phenomena developed by Landau and Khalatnikov.\(^1\),\(^9\)
We evaluate thermal conductivity and viscosity within three ranges of temperatures: $0.3 K \leq T < 0.8 K$ and $T > 0.8 K$. In these temperature ranges, scattering depends on the nature of interactions of elementary excitations, i.e., phonon-phonon, phonon-roton and roton-roton interactions. The scatterings which govern the transport processes and kinetic coefficients of thermal conductivity and viscosity can be determined by the characteristic time $\tau$ of scattering.

In the present paper we shall treat a thin helium film as two-dimensional (2-D) -- less than three atomic layers, namely one statistical layer of 3.6 Å -- and neglect substrate effects. In the calculations we shall use the 2-D excitation dispersion relation obtained microscopically:

$$\varepsilon(p) = c_0 p[1 + \delta_1 p^2 - \delta_2 p^4 + \ldots] ,$$  

$$\varepsilon(p) = \Delta + \frac{1}{2\mu} (p-p_0)^2 ,$$

where $c_0$ is the sound velocity, and $\Delta, \mu$ and $p_0$ are the roton parameters. To evaluate the coefficients of thermal conductivity and viscosity, we shall first calculate the scattering cross section for the various interactions in Sec. II. Then we shall evaluate the characteristic times corresponding to the various scatterings by solving the collision integral, and then obtain thermal conductivity in Sec. III and viscosity in Sec. IV. Finally, we shall give results and discussion in Sec. V in terms of graphs and tables.

II. Scattering cross sections and differential decay rates

In this section we consider the interactions of elementary excitations by the second quantization method. To obtain characteristic times corresponding to the three interactions, we first evaluate the scattering cross
section or the differential decay rate, which are directly related to the collision integral. The collision process of phonon-phonon interactions includes three-phonon process (3PP, \( \vec{p}_1 = \vec{p}_2 + \vec{p}_3 \)), four-phonon process (4PP, \( \vec{p}_1 + \vec{p}_2 = \vec{p}_3 + \vec{p}_4 \)) and five-phonon process (5PP, \( \vec{p}_1 + \vec{p}_2 = \vec{p}_3 + \vec{p}_4 + \vec{p}_5 \)).

The differential cross section and differential decay rate for 3PP in two dimensions are defined as

\[
\frac{d\sigma}{d\Omega} = \left( \frac{2\pi}{\hbar c_0} \right) |< F | \mathcal{M}_3 | I >|^2 \frac{dE}{(2\pi \hbar)^2}, \quad (2.1)
\]

\[
\frac{d\omega}{d\Omega} = \left( \frac{2\pi}{\hbar} \right) |< F | \mathcal{M}_3 | I >|^2 \frac{dE}{(2\pi \hbar)^2}. \quad (2.2)
\]

The 3PP consists of two processes: the direct process of emission of a phonon \( \vec{p}_3 \) by \( \vec{p}_1 = \vec{p}_2 + \vec{p}_3 \), and the reverse process of absorption of a phonon \( \vec{p}_3 \) by \( \vec{p}_1 + \vec{p}_3 = \vec{p}_1 \). The transition amplitude between the initial state \( |I> \) and the final state \( |F> \) is given by

\[
< F | \mathcal{M}_3 | I > = \frac{3!}{2} \frac{(2\pi \hbar)^2}{(2S)^{3/2}} \delta (\vec{p}_1 - \vec{p}_2 - \vec{p}_3) \left\{ \frac{C_0}{\rho_0} \frac{P_0}{p_1 p_3} \right\} \left\{ \frac{C_0}{\rho_0} \frac{P_0}{p_1 p_2 p_3} \right\} \left\{ \frac{C_0}{\rho_0} \frac{P_0}{p_1 p_2 p_3} \right\} \frac{1}{(n_1 + 1)(n_2 + 1)} \frac{1}{(n_3 - 1)}, \quad (2.3)
\]

\[
< F | \mathcal{M}_3 | I > = \frac{3!}{2} \frac{(2\pi \hbar)^2}{(2S)^{3/2}} \delta (\vec{p}_1 - \vec{p}_2 - \vec{p}_3) \left\{ \frac{C_0}{\rho_0} \frac{P_0}{p_1 p_3} \right\} \left\{ \frac{C_0}{\rho_0} \frac{P_0}{p_1 p_2 p_3} \right\} \left\{ \frac{C_0}{\rho_0} \frac{P_0}{p_1 p_2 p_3} \right\} \frac{1}{(n_1 + 1)(n_2 + 1)(n_3 - 1)}, \quad (2.4)
\]

where \( n_p \) is the distribution function of phonons with momentum \( \vec{p} \). Then the total decay rate in both processes becomes

-3-
\[
W = \frac{\pi c_0}{2\hbar \rho_0} (u+1)^2 \int \frac{p_1 p_2 p n_- (n_- + 1)(n_- + 1) \delta (E_F - E_i) \frac{dp_3}{(2\pi \hbar)^2}}{p_1 p_2 p_3}, \quad (2.5)
\]

\[
W = \frac{\pi c_0}{2\hbar \rho_0} (u+1)^2 \int \frac{p_1 p_2 q (n_- + 1)n_- n_- \delta (E_F - E_l) \frac{dp_3}{(2\pi \hbar)^2}}{p_1 p_2 p_3}, \quad (2.6)
\]

where \( u \) is the Grüneisen constant given by \((\rho_0/c_0)(\partial \rho_0/\partial c_0)\).

In 4PP the transition matrix elements \(^{11}\) are given by

\[
\langle F | \mathcal{K} | I \rangle = \langle F | \mathcal{K}_1 | I \rangle + \sum_J \frac{\langle F | \mathcal{K}_J | J \rangle \langle J | \mathcal{K}_J | I \rangle}{E_I - E_J}, \quad (2.7)
\]

where the main contribution is due to the second term, which becomes large as a result of vanishing denominator. This corresponds to the case where \( \delta_1 \) is neglected and the scattering between phonons is collinear. Therefore we should not discard the \( \delta_1 \)-term in Eq. (1.1). Taking account of \( \delta_1 p^2 \), which is much smaller than unity, and small-angle scattering, we can find the maximum value for \( \langle F | \mathcal{K} | I \rangle \). In small-angle scattering all the phonons are moving in the same direction, and the conservation of momentum and energy flow hold. Thus the phonons moving in a given direction attain equilibrium with each other much faster than the phonons in other directions. The differential cross section (Eq.(2.1)) for 4PP becomes

\[
d\sigma(p', p, p', p) = \left( \frac{2\pi}{\hbar c_0} \right) | \langle F | \mathcal{K} | I \rangle |^2 \delta (\varepsilon + \varepsilon_1 - \varepsilon_1') \frac{dp'}{(2\pi \hbar)^2}. \quad (2.8)
\]

Under the condition \( p \ll p_1 \) we obtain

\[
d\sigma = \frac{(u+1)^2 p^2 p' \delta (\varepsilon(p) + \varepsilon(p) - \varepsilon(p'))}{8\pi \hbar^2 \rho_0^2 c_0 \rho (1 - \cos \theta - 3\delta_1 p_1^2)^2} \frac{dp'}{dp'}. \quad (2.9)
\]
As for 4PP above, the direction of momenta of the colliding particles is not changed in the 5PP case. The transition matrix elements in second-order perturbation are

\[ \sum_{i,\Pi} \frac{\langle i | \mathbf{K}_i | \mathbf{I} \times i | \mathbf{K}_\Pi | \Pi \times \Pi | \mathbf{F} \rangle}{(E_i - E_I)(E_\Pi - E_\Pi)} , \quad (2.10) \]

where some terms contain the vanishing denominators under the conditions of \( \delta_1 = 0 \) and collinear scattering. The 5PP has the maximum probability in small-angle scattering and leads to equilibrium for the phonons moving in a given direction. Rather than calculating Eq.(2.10) tediously, we make use of the kinetic coefficient given by Landau and Khalatnikov. 1) The change of rate per unit time in the phonon numbers is

\[ \dot{N}_{ph} = - \int \int \int \left[ n_i n_2 (n_i + 1)(n_2 + 1) - (n_i + 1)(n_2 + 1)n_i n_2 \right] \frac{dp_i dp_2 dp_3}{(2\pi)^3} , \quad (2.11) \]

where \( dw \) is the differential decay rate defined by Eq.(2.2), which is proportional to \( p^2 \). \( \dot{N}_{ph} \) can be expressed in terms of the kinetic coefficient \( \Gamma_{ph} \) as

\[ \dot{N}_{ph} = - \Gamma_{ph} \mu_{ph} , \quad (2.12) \]

where \( \mu_{ph} \) is the chemical potential of phonons. The phonon distribution function \( n \) has small deviation from the equilibrium distribution function \( n_0 \). The distribution function \( n \) can be expanded as a function of chemical potential as follows

\[ n - n_0 = n_0 (n_0 + 1) \frac{\mu_{ph}}{k_B T} . \quad (2.13) \]
To simplify Eq. (2.11), we replace \( n_1, n_2, n_3 \) and \( n \) by the equilibrium distribution \( n_{10}, n_{20}, n_{30} \) and \( n_{40} \), and instead of \( n \), we substitute Eq. (2.13) into Eq. (2.11). Then Eq. (2.11) becomes

\[
\Gamma_{ph} = \frac{1}{k_B T} \iint n_{10} n_{20} n_{30} \left( n_{40} + 1 \right) \left( n_{50} + 1 \right) dw \frac{dp_1 dp_2 dp_3}{(2\pi \hbar)^6}.
\] (2.14)

Since \( n_{40} \) and \( n_{50} \) are much smaller than unity, they may be neglected without any disturbance in Eq. (2.14), and the integration of \( dw \) is replaced by average \( \bar{w} \). Then Eq. (2.14) becomes

\[
\Gamma_{ph} = \frac{1}{k_B T} \iint n_{10} n_{20} n_{30} \bar{w} \frac{dp_1 dp_2 dp_3}{(2\pi \hbar)^6}.
\] (2.15)

Since \( \bar{w} \) and \( \mathcal{K}_3 \) are proportional to \( \sim p^2 \) and \( \sim p^{12} \), respectively, the integral of Eq. (2.15) is proportional to \( p^8 \). Averaging the momentum of phonon gives

\[
\Gamma_{ph} = a T^7.
\] (2.16)

Here \( a \) is constant, which can be determined experimentally by the attenuation coefficient of ultrasonic waves.

Now we return to the scattering of phonons by rotons. We consider a roton in the presence of the phonon field. We can treat this roton as a particle in a moving liquid \(^4\)He. Therefore there appears an additional term \(- \vec{p} \cdot \vec{v}\). This can be written in symmetric form

\[
-\frac{1}{2} \left( \vec{p} \cdot \vec{v} + \vec{v} \cdot \vec{p} \right),
\] (2.17)

where \( \vec{p} \) and \( \vec{v} \) are the momentum and velocity operators.\(^{11} \) The phonon field
changes the density of the medium, and thus we may expand the roton energy
in terms of the density \( \rho' \) to second order (\( \rho' = \rho - \rho_0 \)) as

\[
\delta r = \delta r_0 + \frac{3}{\delta \rho} \left[ \delta + \frac{1}{2 \mu} (P - P_0)^2 \right] \rho' + \frac{1}{21} \frac{\delta^2}{\delta \rho^2} \left[ \delta + \frac{1}{2 \mu} (P - P_0)^2 \right] \rho'^2 + \ldots ,
\]

(2.18)

where \( \delta r_0 \) is given by Eq. (1.2). Since the value of most rotons is close to
\( P_0 \), we may neglect \( (P - P_0) \) and replace \( P \) by \( P_0 \). We may also drop the term
\( (\partial \delta / \partial \rho) \rho' \), which is much smaller than (2.17). Then the interaction energy
between phonons and rotons can be expressed as

\[
V = -\frac{1}{2} \left( \vec{P} \cdot \vec{v} + \vec{v} \cdot \vec{P} \right) + \frac{1}{2} \left[ \frac{\delta^2 \Delta}{\delta \rho^2} + \frac{1}{\mu} \left( \frac{\delta P_0}{\delta \rho} \right)^2 \right] \rho'^2 .
\]

(2.19)

We note that the terms in the second bracket of Eq. (2.19) have magnitude
on the order of \( 10^{-1} \) to \( 1 \) in 3-D liquid helium\textsuperscript{12}.

When the roton changes momentum \( \vec{P} \) to \( \vec{P}' \), it absorbs a phonon with moment-
\( \vec{P} \) and emits a phonon with momentum \( \vec{P}' \). In these processes we may con-
sider two intermediate processes, i.e., (I) \( \vec{P} + \vec{p} \rightarrow \vec{P}' = \vec{P} + \vec{p} - \vec{p}' \) and (II)
\( \vec{P} - \vec{p}' \rightarrow \vec{P}' = \vec{P} - \vec{p}' + \vec{p} \). Since the roton momentum is much larger than that
of the phonon, we may view this interaction as similar to that between heavy
and light particles. The momentum and the energy conservation law in colli-
sion processes can be written as

\[
cp + \frac{1}{2 \mu} (P - P_0)^2 = cp' + \frac{1}{2 \mu} (|P + \vec{p} - \vec{p}'| - \vec{P}_0)^2 .
\]

(2.20)

Under the conditions \( p, p' \ll P_0 \) and \( \epsilon = cp \ll 3 \mu c^2 \), Eq. (2.20) becomes
\[ p - p' = \frac{1}{2\mu c^2} \left( \hat{p}_0 \cdot (\hat{p} - \hat{p}') \right)^2 = \frac{p^2}{2\mu c} (\hat{m}(\hat{m} - \hat{n}'))^2, \]  
\[ (2.21) \]

where \( \hat{m}, \hat{n} \) and \( \hat{n}' \) are unit vectors directed along \( \hat{p}_0, \hat{p} \) and \( \hat{p}' \), respectively. Therefore energy conservation implies \( p \approx p' \). This means that the light particles do not change the magnitude of momentum but change its direction. Taking account of \( p, p' \ll P_0 \) and \( P \approx P_0 \), the matrix element (Eq. (2.1)) in second-order perturbation can be obtained as

\[ \chi_{IF} = \frac{P_0 P}{2P_0} \left[ [(\hat{m} \cdot \hat{n}) + (\hat{m} \cdot \hat{n}')] (\hat{n} \cdot \hat{n}') + \frac{P_0}{\mu c} (\hat{m} \cdot \hat{n})^2 (\hat{m} \cdot \hat{n}')^2 + \Lambda \right], \]  
\[ (2.22) \]

\[ \Lambda = \frac{\rho^2}{P_0 c} \left( \frac{\partial^2 \Delta}{\partial \rho^2} + \frac{1}{\mu} \left( \frac{\partial P_0}{\partial \rho} \right)^2 \right). \]  
\[ (2.23) \]

Substituting Eqs. (2.22) - (2.23) into Eq. (2.1) and performing the integration over \( p' \), we obtain

\[ d\sigma = \frac{P_0^2 P^3}{8\pi \hbar^2 \rho_0^2 c^2} \left[ [(\hat{m} \cdot \hat{n}) + (\hat{m} \cdot \hat{n}')] (\hat{n} \cdot \hat{n}') + \frac{P_0}{\mu c} (\hat{m} \cdot \hat{n})^2 (\hat{m} \cdot \hat{n}')^2 + \Lambda \right]^2 d\theta. \]  
\[ (2.24) \]

Averaging Eq. (2.24) over all directions of roton momentum, we finally get

\[ d\sigma = \frac{P_0^2 P^3}{8\pi \hbar^2 \rho_0^2 c^2} \left[ (1 + \cos \psi) \cos \psi + \frac{1}{128} \left( \frac{P_0}{\mu c} \right)^2 (35 \cos^4 \psi + 3\sin^4 \psi \right. \]
\[ + 30 \cos^2 \psi \sin^2 \psi + \frac{1}{4} \frac{P_0 A}{\mu c} (3 \cos^2 \psi + \sin^2 \psi) + A^2 \right] d\psi, \]  
\[ (2.25) \]

where \( \psi \) is the angle between the incident and scattered phonons (see Fig. 1).

We shall now examine roton-roton scattering. Since the character of interaction between rotons is not known, we may assume the short-range potential given by Landau and Khalatnikov \(^{13}\) and take the roton interaction to be a delta function potential.
\[ V = V_0 \delta (\vec{r} - \vec{r}_1), \]  

(2.26)

where \( V_0 \) is the interaction constant which can be determined experimentally by viscosity measurements, and \( \vec{r} \) and \( \vec{r}_1 \) are the radius vectors of rotons.

We construct the symmetrized pairwise plane waves over incoming and outgoing rotons as

\[
\psi(\vec{P}, \vec{P}_1) = \frac{1}{\sqrt{2}} \left\{ e^{i\frac{\vec{P}\cdot\vec{r}}{\hbar}} \frac{i}{\hbar} (\vec{P}\cdot\vec{r} + \vec{P}_1\cdot\vec{r}) \frac{i}{\hbar} (\vec{P}\cdot\vec{r}_1 + \vec{P}_1\cdot\vec{r}) \right\},
\]

(2.27)

\[
\nu(\vec{P}', \vec{P}_1') = \frac{1}{\sqrt{2}} \left\{ e^{i\frac{\vec{P}'\cdot\vec{r}}{\hbar}} \frac{i}{\hbar} (\vec{P}'\cdot\vec{r} + \vec{P}_1\cdot\vec{r}) \frac{i}{\hbar} (\vec{P}'\cdot\vec{r}_1 + \vec{P}_1\cdot\vec{r}) \right\}.
\]

The differential decay rate from before to after collision is

\[
d\omega = \frac{2\pi}{\hbar} | V_{AF} |^2 \delta(E + E_i - E' - E_i') \frac{d\vec{P}'d\vec{P}_1'}{(2\pi\hbar)^2},
\]

(2.28)

where the matrix element \( V_{AF} \) is

\[
V_{AF} = V_0 S^{-\frac{1}{2}} \int \psi(\vec{P}, \vec{P}_1) \delta(\vec{r} - \vec{r}_1) \psi(\vec{P}', \vec{P}_1') d\vec{r} d\vec{r}_1
\]

\[
= 2 V_0 S^{-\frac{1}{2}} \int e^{i\frac{\vec{P}\cdot\vec{r}_1 + \vec{P}_1\cdot\vec{r}_1}{\hbar}} d\vec{r}.
\]

(2.29)

Performing integration over \( \vec{P}_1' \) in Eq. (2.28), we obtain

\[
d\omega = \frac{8\pi}{\hbar} | V_0 |^2 \delta(E + E_i - E' - E_i') \frac{d\vec{P}'}{(2\pi\hbar)^2}.
\]

(2.30)
Dividing Eq. (2.30) by the relative velocity of rotons given as

\[ v = \left| \frac{\partial E_i}{\partial P} - \frac{\partial E}{\partial P_1} \right|, \quad (2.31) \]

we can obtain the differential scattering cross section.

As mentioned earlier in the discussion of the scattering of phonons by rotons, most rotons have the value close to \( P_0 \). Thus the change of momentum after collision is very small in comparison with \( P_0 \). Let us take \( \theta \) as an angle between the incident rotons with momenta \( \vec{P} \) and \( \vec{P}_1 \) before collision and introduce the variable \( f \) (Fig. 2). Then the roton momenta after collision can be expressed as

\[
P' = P_x + f_x \cos \frac{\theta}{2} + f_y \sin \frac{\theta}{2},
\]

\[
P'_1 = P_x - f_x \cos \frac{\theta}{2} + f_y \sin \frac{\theta}{2}. \quad (2.32)
\]

Here, we have made use of \( P \approx P_1 \approx P_0 \) and \( |f| \ll P_0 \). From the conservation of energy we have

\[
f_x^2 \cos^2 \frac{\theta}{2} + f_y^2 \sin^2 \frac{\theta}{2} = \frac{1}{2} (P - P_0)^2 + \frac{1}{2} (P_1 - P_0)^2. \quad (2.33)
\]

To obtain the total scattering cross section, we integrate Eq. (2.30) together with Eqs. (2.31) and (2.32) over the momentum of the scattered particles to get the total scattering cross section

\[
\sigma = \frac{4\mu |v|}{\left| \frac{\partial E}{\partial P} - \frac{\partial E}{\partial P_1} \right|^2} \cdot (2.34)
\]
and the average collision time between rotons becomes

\[
\frac{1}{\tau_r} = \sigma \left| \frac{\partial E}{\partial \rho} - \frac{\partial E}{\partial \rho^*} \right| N_r = \frac{4\mu \langle \nu_r \rangle^2}{\hbar^2 \sin \theta} N_r,
\]

where \(N_r\) is number of rotons per unit area given by

\[
N_r = \left( \frac{\mu k_B T}{2\pi} \right)^{\frac{1}{2}} \frac{p_r}{\hbar^2} e^{-\frac{\mu}{k_B T}}.
\]

III. Coefficient of thermal conductivity

The equilibrium distribution function \(n_0\) of excitation satisfies the kinetic equation

\[
\frac{\partial n}{\partial t} + \frac{\partial n}{\partial r} \cdot \frac{\partial \mathbf{v}}{\partial \rho} - \frac{\partial n}{\partial \rho} \cdot \frac{\partial \mathbf{v}}{\partial r} = J(n),
\]

with vanishing collision integral. When the equilibrium is disturbed, we assume that the nonequilibrium distribution function \(n\) deviates slightly from equilibrium. The small deviation can be determined by the first derivatives of the velocities \(\mathbf{v}_n, \mathbf{v}_s\) and the thermodynamic variables, since function can be written as \(n = n_0 + n_1\), where \(n_1 \ll n_0\). Putting \(n\) into the left-hand side in Eq. (3.1), it is sufficient to keep only the differentiation of \(n_0\) since the derivative of \(n_1\) makes higher derivatives which can be neglected. For the collision integral on the right-hand side we only keep the linear terms in \(n_1\). With the help of the continuity equation, entropy
equation and superfluid equation of motion, we can write the kinetic equation (Eq. (3.1)) as

\[
\frac{n'}{k_B T} \left( \frac{1}{T} \frac{\partial T}{\partial \rho} \varepsilon - \frac{\partial \varepsilon}{\partial \rho} \right) \vec{v} \cdot (i - \rho \vec{v}) + \left[ \frac{1}{T} \left( \frac{\partial T}{\partial \rho} \rho + \frac{\partial T}{\partial S} S \right) \varepsilon - \frac{\partial \varepsilon}{\partial \rho} \right] \vec{v} \cdot \vec{v} =
\]

\[
+ \frac{\vec{v} T}{T} \cdot \left( \rho \frac{ST}{\rho n} - \varepsilon \frac{\partial \varepsilon}{\partial \rho} - \frac{\partial \varepsilon}{\partial \rho} \frac{\partial \varepsilon}{\partial \rho} \right) \frac{\partial \varepsilon}{\partial \rho} \right] \vec{v} \cdot \vec{v} = J(n), \tag{3.2}
\]

where \(n' = -n(n + 1)\).

When there exists a temperature gradient in superfluid \(^4\)He, there is not only transport of heat but also an irreversible heat flow which can be expressed by the coefficient of thermal conduction given as

\[
\vec{q} = -\kappa \vec{v} T. \tag{3.3}
\]

Comparison of Eq. (3.3) with Eq. (3.2) for thermal conductivity \(\kappa\) gives the kinetic equation with a temperature gradient,

\[
\frac{n'}{k_B T} \frac{\partial T}{\partial x} \cos \theta \left[ \rho \frac{ST}{\rho n} - \varepsilon \frac{\partial \varepsilon}{\partial \rho} \right] = J(n), \tag{3.4}
\]

where \(\theta\) is the angle between \(\vec{p}\) and \(\vec{v} T\). The phenomena associated with thermal conduction in bulk liquid \(^4\)He have aspects in common with thermal transport properties of ordinary classical liquids. However, there are specific features of thermal transport which are connected with the unusual elementary excitations of liquid \(^4\)He. The left-hand side of Eq. (3.4) is always zero for a pure phonon gas, and thus the corresponding thermal conductivity vanishes.

The thermal conductivity \(\kappa\) consists of two parts, i.e., the phonon \(\kappa_{ph}\) and the roton \(\kappa_r\):
\[ \kappa = \kappa_{ph} + \kappa_r. \]  

(3.5)

Let us first consider the roton part. This is determined by the roton-roton scattering process. As mentioned earlier in Sec. II, the character of the roton-roton interaction is not well known, and we thus obtained the average collision time \( t_r \) under the assumption of the delta function potential. Since we have only to know the temperature dependence on \( \kappa_r \), we replace the collision integral by the following:

\[ J(n) = - \frac{n - n_0}{t_r}. \]  

(3.6)

Substitution of Eq. (3.6) in Eq. (3.4) yields

\[ n - n_0 = - \frac{n'}{k_B T} \nabla T \cdot \left[ \frac{ST}{\rho_n} - \frac{\partial \varepsilon}{\partial P} \right] t_r. \]  

(3.7)

Substituting Eq. (3.7) into the expression for the energy flow

\[ \bar{q} = \int \frac{\partial \varepsilon}{\partial P} \varepsilon(P) (n - n_0) \frac{dP}{(2\pi)^2}, \]  

(3.8)

and comparing this result with Eq. (3.3), we get

\[ \kappa_r = \frac{t_r}{2k_B T} \int n' \varepsilon \frac{\partial \varepsilon}{\partial P} \cdot \left( \frac{ST}{\rho_n} - \frac{\partial \varepsilon}{\partial P} \right) \frac{dP}{(2\pi)^2}. \]  

(3.9)

With the help of \( n' = - n \) and Eq. (1.2), we finally obtain the roton part of thermal conductivity as

-13-
\[ \kappa_r(T) = \frac{\tau_r A^2 N_r}{2\mu T} \left[ 1 + \frac{3k_BT}{\Delta} + \frac{15}{4} \left( \frac{k_BT}{\Delta} \right)^2 - \frac{2\mu S}{\rho \nu k_B} \left( \frac{k_BT}{\Delta} \right) + \frac{3}{2} \left( \frac{k_BT}{\Delta} \right)^2 \right]. \] 

(3.10)

According to the scattering processes in Sec. II, the collision integral

\[ J(n) = J_{3PP}(n) + J_{4PP}(n) + J_{5PP}(n) + J_{ph\tau}(n). \] 

(3.11)

The 4PP do not change the total number of phonons but have a characteristic temperature \( T' \) in a given direction, which is different from the temperature \( T \) in the equilibrium state. The law of energy conservation yields

\[ \int J_{4PP}(n) \, dp = 0. \] 

(3.12)

The total number of phonons traveling in a given direction is changed by small-angle 3PP and 5PP. Therefore the distribution function, which not only depends on temperature \( T' \) but also the chemical potential \( \alpha' \), can be written as

\[ n = \exp \left[ (\alpha' + \frac{pc}{k_B T'}) - 1 \right]. \] 

(3.13)

Expanding Eq. (3.13) as a function of \( T' - T \), we can express Eq. (3.13) in terms of equilibrium distribution function

\[ \delta n = n - n_0 = -n_0 (n_0 + 1) \left( \alpha' - \frac{pc}{k_B T} \frac{T'-T}{T} \right). \] 

(3.14)

Since the left-hand side of Eq. (3.4) is involved in \( \theta \), \( \alpha' \) and \( T' - T \) depend naturally on \( \theta \). To solve Eq. (3.4) we should take the forms
\[
\alpha' = \alpha \cos \theta, \quad \frac{(T' - T)}{T} = \delta \cos \theta,
\]

(3.15)

where \( \alpha \) and \( \delta \) are constants to be determined by the kinetic equation. Considering the conservation of phonon numbers in a given direction and conservation of energy, the integrations

\[
\int J_{3\rho\rho}(n) \varepsilon dp, \quad \int J_{4\rho\rho}(n) \varepsilon dp, \quad \int J_{5\rho\rho}(n) \varepsilon dp
\]

vanish and Eq. (3.4) becomes

\[
\int \frac{n'}{k_B^2} \cos \theta \frac{\partial T}{\partial x} \left[ p \frac{ST}{\rho_n} - \varepsilon \frac{\partial \varepsilon}{\partial p} \right] \varepsilon dp = \int \left[ J_{3\rho\rho}(n) + J_{5\rho\rho}(n) + J_{\rho\rho}(n) \right] \varepsilon dp,
\]

(3.16)

\[
\int \frac{n'}{k_B^2} \cos \theta \frac{\partial T}{\partial x} \left[ p \frac{ST}{\rho_n} - \varepsilon \frac{\partial \varepsilon}{\partial p} \right] \varepsilon dp = \int J_{\rho\rho}(n) \varepsilon dp.
\]

(3.17)

From Eqs. (2.5) - (2.6) the collision integral for the 3PP becomes

\[
J_{3\rho\rho}(n) = -\frac{\pi c_0}{\hbar p_0^2} (u + 1)^\prime \int p_1 p_2 p_3 \delta n(n_{p_1} - n_{p_2}) \delta (\varepsilon_{p_1} - \varepsilon_{p_2}) \frac{dp}{(2\pi \hbar)^2},
\]

(3.18)

where \( \delta n \) is equal to \( (n_{p} - n_{p_0}) \) and \( n_{p_0} \) represents the equilibrium distribution functions for the phonons with momentum \( p \). Making use of Eqs. (2.12) - (2.13), the collision integral for the 5PP can be written as

\[
\int J_{5\rho\rho}(n) dp = 2\pi \hbar^2 k_B T \alpha' \Gamma_{\rho\rho}.
\]

(3.19)

We now evaluate the collision integral in the scattering of phonons by rotons. When a phonon with momentum \( \vec{p} \) changes to momentum \( \vec{p}' \) directed at angle \( \theta' \) after collision by a roton, the probability per unit length that a
particle undergoes collision is \( N \, d\sigma \), where \( N \) is the roton distribution given by Eq. (2.36) and \( d\sigma \) is given by Eq. (2.25). Then the collision integral \( J_{\text{ph-r}}(n) \) can be written as

\[
J_{\text{ph-r}}(n) = - N \, C_0 \int \left[ n(p, \theta, T) - n(p', \theta', T') \right] \, d\sigma. \tag{3.20}
\]

Here, \( \theta \) is the angle of the incident phonon with momentum \( \vec{p} \) with respect to the x-axis. Using Eqs. (3.14) - (3.15) for the difference between distributions, we obtain

\[
J_{\text{ph-r}}(n) = \cos \theta \, n_0 \, (n_0 + 1) (\alpha - \beta \, \frac{p_c}{k_B T} \, N \, \frac{p_o^2 \, \rho^3}{8 \hbar^3 \rho_s \, c_0} \times \left[ \frac{1}{4} + \frac{9}{32} \, \left( \frac{p_o}{\mu c} \right)^2 + \frac{p_o}{\mu c} \, A + 2A^2 \right]. \tag{3.21}
\]

Substituting Eqs. (3.18) and (3.21) together with Eq. (3.19) and \( n' = - n_0 \, (n_0 + 1) \) in Eqs. (3.16) and (3.17), and performing the momentum integral, we obtain

\[
\frac{1}{T} \frac{\partial T}{\partial x} \left( C - \frac{ST}{\rho c} \right) \frac{2 \xi (2) 6 \xi (6)}{3 \xi (3) 4 \xi (4)} = \frac{1}{\tau_{\text{ph-r}}} \left[ \alpha - \beta \, \frac{5 \xi (5)}{4 \xi (4)} \right] + \frac{\alpha}{\tau_{\text{3pp}}}, \tag{3.22}
\]

and

\[
\frac{1}{T} \frac{\partial T}{\partial x} \left( C - \frac{ST}{\rho c} \right) \frac{6 \xi (6)}{5 \xi (5)} = \frac{1}{\tau_{\text{ph-r}}} \left[ \alpha - \beta \, \frac{6 \xi (6)}{5 \xi (5)} \right]. \tag{3.23}
\]

Here \( \tau_{\text{3pp}} \), \( \tau_{\text{5pp}} \) and \( \tau_{\text{ph-r}} \) are the characteristic times (see the Appendix).
which characterize each collision processes, given by

\[
\frac{1}{\tau_{\text{ph-r}}(T)} = \frac{6!5(6)}{3!5(3)} \frac{P_0^2 (k_B T)^2}{8\hbar \rho^2 C^4} \left( \frac{1}{4} + \frac{9}{32} \left( \frac{P_0}{\mu C} \right)^2 + \left( \frac{P_0}{\mu C} \right) A + 2A^2 \right),
\]

(3.24)

\[
\frac{1}{\tau_{5\text{pp}}(T)} = \frac{6!5(6)}{3!5(3)4!5(3)} \frac{2\pi \hbar C^2 a}{k_B} \tau^4,
\]

(3.25)

and

\[
\frac{1}{\tau_{3\text{pp}}(T)} = \frac{2!5(2)6!5(6)}{4!5(4)} \frac{(u+1)^2 k_B^4}{8\pi \hbar \rho C^4} \tau^4.
\]

(3.26)

Solving Eqs. (3.22) and (3.23) for \( \alpha \) and \( \beta \), we obtain

\[
\alpha = \left( \frac{8.071}{0.186 + \frac{1}{\tau_{\text{ph-r}}} + \frac{1}{\tau_{5\text{pp}}} + \frac{1}{\tau_{3\text{pp}}}} \right) \frac{1}{T} \frac{\partial T}{\partial x} \left( C - \frac{ST}{\rho C} \right),
\]

(3.27)

\[
\beta = \left( \frac{1.372}{0.186 + \frac{1}{\tau_{\text{ph-r}}} + \frac{1}{\tau_{5\text{pp}}} + \frac{1}{\tau_{3\text{pp}}}} \right) \frac{1}{T} \frac{\partial T}{\partial x} \left( C - \frac{ST}{\rho C} \right),
\]

(3.28)

where we introduced \( A \) and \( B \) for simplification. Substitution of Eqs. (3.27) and (3.28) in Eq. (3.14) yields

\[
n - n_0 = - n_0 (n_0 + 1) \cos \theta \left( A - B \frac{P C}{k_B T} \right) \frac{1}{T} \frac{\partial T}{\partial x} \left( C - \frac{ST}{\rho C} \right),
\]

(3.29)

and the energy flux (Eq. (3.8)) for the phonon-roton process can be evaluated...
as
\[
q = \int \frac{\partial e}{\partial p} \varepsilon (n - n_0) \cos \theta \frac{dp}{(2\pi)^2}
\]
\[= - \frac{k^3 n^2}{4\pi h^2 C} \left[ C - \frac{ST}{\rho_n} \right] [3.290A - 7.212B] \frac{\partial T}{\partial x}.
\]

Comparison of Eq. (3.30) with Eq. (3.3) gives the coefficient of thermal conduction:
\[
\kappa_{pn}(T) = \frac{1.803k^3 T^3}{\pi h^2 C^3} \left[ C^2 - \frac{ST}{\rho_n} \right] \left[ \tau_{ph-r} + \frac{\frac{0.186}{\tau_{ph-r}} + \frac{1}{\tau_{5PP}} + \frac{1}{\tau_{3PP}}}{\frac{84}{1 + 0.75 \tau_{ph-r}/\tau_{5PP}} + \frac{1 + 8 \tau_{ph-r}/\tau_{5PP}}{\tau_{3PP}}} \right] \frac{\partial T}{\partial x}.
\]

We note that the coefficient of the thermal conduction in bulk liquid helium is given by
\[
\kappa(T) = 2 \times 10^3 \frac{1}{T} + T^{-3/2} e^{\Delta / k_B T} \left( 1 - \frac{ST}{\rho_n C^2} \right)
\]
\[
\times \left\{ \begin{array}{ll}
84 & , \ T > 0.9 \ K \\
\frac{1 + 0.75 \tau_{ph-r}/\tau_{3PP}}{1 + 8 \tau_{ph-r}/\tau_{5PP}} & , \ T > 0.9 \ K \\
7.8 & , \ T < 0.9 \ K
\end{array} \right.
\]

(3.32)
IV. Viscosity

In this section we investigate the first viscosity through similar calculations to those used above for the thermal conductivity. Equation (3.4) vanishes for the case of a pure phonon gas, and thus the corresponding coefficient \( \kappa(T) \) becomes zero. However, the kinetic equation

\[
\frac{\partial n}{\partial t} + \nabla \cdot n = J(n) \tag{4.1}
\]

does not vanish for the pure phonon gas near zero temperature. Therefore, we should consider the contribution of the pure phonon gas to viscosity. Let us consider the macroscopic motion of liquid helium (which does not depend explicitly on time) with velocity \( \vec{U} \) and the gradient of \( \vec{U} \) directed along the x-axis. Then Eq. (4.1) becomes

\[
\nabla \cdot n = v \frac{\partial n}{\partial x} = J(n). \tag{4.2}
\]

The equilibrium distribution function of roton in liquid helium with velocity \( \vec{U} \) can be expressed by

\[
n_0 = \exp \left[ - \frac{\Delta}{k_B T} - \frac{(P-P_0)^2}{2 \mu k_B T} + \frac{\vec{P} \cdot \vec{U}}{k_B T} \right], \tag{4.3}
\]

where we used Eq. (1.2). Substituting \( n = n_0 \) and the roton velocity \( v = (P - P_0)/\mu \) in Eq. (4.2), we get

\[
n_0 \frac{P_0 (P-P_0)}{\mu k_B T} \frac{\partial U}{\partial x} \cos \theta \sin \theta = J_3(n), \tag{4.4}
\]

where \( \theta \) is the angle between the roton momentum \( P \) and the x-axis. The colli-
sion integral can be replaced by Eq. (3.6) to give

\[ n - n_0 = -t \frac{(P - P_0) P}{\mu k_B T} n_0 \cos \theta \sin \theta \frac{\partial U}{\partial x}. \]  

(4.5)

Substituting Eq. (4.5) into the following stress tensor of 2-D liquid helium

\[ \sigma_{xy} = \int \frac{P}{y} v_x (n - n_0) \frac{\partial P}{(2\pi \hbar)^2}. \]  

(4.6)

and performing the integral over the momentum space, we arrive at the expression

\[ \sigma_{xy} = -t \frac{P}{\mu} N \frac{\partial U}{\partial x}. \]  

(4.7)

Comparing Eq. (4.7) with the general expression of viscosity

\[ \sigma_{xy} = -\eta \frac{\partial U}{\partial x}, \]  

(4.8)

we obtain the coefficient of viscosity for the roton part as

\[ \eta_r = \frac{p^2}{\mu} \tau r N_r. \]  

(4.9)

The equilibrium distribution function of the phonon gas is

\[ n_0 = \left\{ \exp \left( \frac{cp - U \cdot \vec{P}}{k_B T} \right) - 1 \right\}^{-1}. \]  

(4.10)

Let us assume the distribution function to deviate slightly from \( n_0 \), i.e.,

\[ n = n_0 + \delta n, \]  

which satisfies Eq. (4.1). Substituting Eq. (4.10) into Eq.
(4.2) we get

\[ n_0 (n_0 + 1) \frac{c_p}{k_B T} \frac{\partial U}{\partial x} \cos \theta \sin \theta = J(n). \]  \tag{4.11}

Solving Eq. (4.11) we can obtain the phonon part of the viscosity. It is necessary to consider \( J(n) \) in the various collision processes. Then the collision integral \( J(n) \) in Eq. (4.11) can be replaced by Eq. (3.10). Through the same processes that we argued in Sec. III, we obtain the following two equations:

\[
\int n_0 (n_0 + 1) \frac{c_p}{k_B T} \frac{\partial U}{\partial x} \cos \theta \sin \theta \, dp = \int [J_{3pp}(n) + J_{5pp}(n)]
\]

\[ + J'_{ph-r}(n) \, dp, \tag{4.12} \]

\[
\int n_0 (n_0 + 1) \frac{c_p}{k_B T} \frac{\partial U}{\partial x} \cos \theta \sin \theta \, \varepsilon(p) \, dp = \int J'_{ph-r}(n) \, \varepsilon(p) \, dp. \tag{4.13} \]

We can express the distribution function by Eq. (3.14), except that now the dependence of \( \alpha' \) and \( (T' - T)/T \) on the angle \( \theta \) is given by

\[ \alpha' = \alpha \cos \theta \sin \theta, \quad (T' - T)/T = \beta \cos \theta \sin \theta. \]  \tag{4.14}

instead of Eq. (3.15).

In Eq. (4.12) the collision integrals \( J_{3pp}(n) \) and \( J_{5pp}(n) \) are given by Eqs. (3.18) and (3.19) respectively. Using Eqs. (3.15) - (3.20), we obtain the collision integral \( J'_{ph}(n) \):
Here, we note that Eq. (4.15) is slightly different from Eq. (3.21), because Eq. (4.14) contains an extra sinθ term. With the use of similar calculations for Eqs. (3.16) – (3.26), we obtain α, β and τₚₕ⁻¹ as

\[
\alpha = \left[ \frac{8.071}{0.186 + \frac{1}{\tau_{ph-r}^3PP} + \frac{1}{\tau_{3PP}}} \right] \frac{\partial U}{\partial x} = A' \frac{\partial U}{\partial x} \beta
\]  

(4.16)

\[
\beta = \left[ -\tau_{ph-r}^{-1} + \frac{1.372}{0.186 + \frac{1}{\tau_{ph-r}^3PP} + \frac{1}{\tau_{5PP}} + \frac{1}{\tau_{3PP}}} \right] \frac{\partial U}{\partial x} = B' \frac{\partial U}{\partial x},
\]  

(4.17)

and

\[
\tau_{ph-r}^{-1} = \frac{6k(6)P_0^2kT^2}{3k(3)6\hbar^3\rho^2C^4 \cdot \tau} \left[ \frac{1}{2} + \frac{5}{32} \left( \frac{P_0}{\mu C} \right)^2 + \frac{3}{4} \left( \frac{P_0}{\mu C} \right) + 2\lambda^2 \right].
\]  

(4.18)

where Eq. (4.18) is not equal to Eq. (3.24). Substitution of Eqs. (4.16) – (4.17) in Eq. (3.14) yields

\[
\delta n = -n_b(n_b + 1) \left( A' - B' \frac{P_0}{kT} \right) \frac{\partial U}{\partial x}.
\]  

(4.19)

Combining Eq. (4.19) with Eq. (4.16) and integrating over momentum space gives

\[
\sigma_{xy} = -\frac{C}{16\pi h^2} \left( \frac{kT}{C} \right)^3 \left[ 3.290A' - 7.212 B' \right] \frac{\partial U}{\partial x}.
\]  

(4.20)

Comparing Eq. (4.20) with Eq. (4.8), we get the phonon part of the coefficient
of the first viscosity:

\[
\eta_{ph}(T) = \frac{7.212(k_B T)^3}{16 \pi h^2 C^2} \cdot \frac{\tau}{\tau - r_{ph-r}} + \frac{2.310}{\tau - r_{5PP}} + \frac{1}{\tau - r_{3PP}}. \tag{4.21}
\]

From the theory and experiments of attenuation of ultrasonic sound waves,\textsuperscript{14)} we can confirm that at near-zero temperature the contribution of 3PP to the viscosity plays a main role, and 4PP establish only the equilibrium of energy. Therefore, we consider the 3PP contribution separately from other contributions. The kinetic equation for 3PP in Eq. (4.11) becomes

\[
\eta_0 (n_0 + 1) \frac{\partial \rho}{k_B T} \frac{\partial U}{\partial x} \cos \theta \sin \theta = J_{3PP}(n). \tag{4.22}
\]

Since the distribution function of phonons depends on the chemical potential \( \alpha \), Eqs. (3.14) - (3.15) become

\[
\delta n = n - n_0 = - \eta_0 (n_0 + 1) \alpha', \quad \alpha' = \alpha \cos \theta \sin \theta. \tag{4.23}
\]

With a similar calculation for Eqs. (3.16) - (3.26), we obtain the stress tensor

\[
\sigma_{xy} = \frac{21\pi(2)^7 6\pi(6) k_B T^3}{314\pi^2 (3\pi(3))(4)} \frac{k_B T^3}{16 \pi h^2 C^2} \tau_{3PP} \frac{\partial U}{\partial x}. \tag{4.24}
\]

From comparison of Eq. (4.24) with Eq. (4.8) we obtain the phonon part of the coefficient \( \eta_{ph} \) near zero temperature as
\[ \eta_{ph}(T) = \frac{2.645}{\pi^2 \hbar^2 c^2} k_B^3 T^3 \tau_{pp}. \] (4.25)

We note that the coefficient of the first viscosity in bulk liquid helium is given by

\[
\eta_{ph}(T) = \begin{cases} 
3.75 \times 10^{-8} T^{-1/2} e^{\frac{\Delta/k_B T}{1 + 8 \frac{\tau_{ph}}{\tau}}}, & T > 0.9 \text{ K} \\
3.5 \times 10^{-9} T^{-1/2} e^{\frac{\Delta/k_B T}{1 + 2.15 \times 10^{-2} T^{1/2} e^{\frac{\Delta/k_B T}{1 + 8 \frac{\tau_{ph}}{\tau}}}}}, & T < 0.9 \text{ K}
\end{cases}
\] (4.26)

V. Results and discussion

In the previous sections we have evaluated the scattering cross sections and characteristic times for various interactions of the elementary excitations. Using these results we have obtained the coefficients of thermal conduction and first viscosity. To investigate the temperature variation of the coefficients \( \kappa(T) \) and \( \eta(T) \), we adopt the parameters which are determined from the specific heat data of Bretz et al.\(^{15}\). The parameters are listed in Table I. With this choice we obtained \( c = 84.06 \text{ m/s} \), which is smaller than the value \( 157 \text{ m/s} \) of Hipólito and Lobo,\(^{16}\) but is very close to the experimental value of \((76 \pm 2) \text{ m/s}\) of Wushburn et al.\(^{17}\). The parameters \( n, A \) and \( a \) in Eqs. (2.9), (2.23) and (2.16) for two dimensions are assumed to be \( 1.8,18\) \( 0.425^9 \) and \( 1.0 \times 10^{13} \) used by previous workers for the bulk case.

The coefficient of the thermal conduction is given by Eqs. (3.10) and
(3.31). We can confirm easily that Eq. (3.4) vanishes by considering only a
case: phonon gas because of the peculiar excitation of liquid helium. There-
fore, the thermal conduction depends on the interactions between excitations,
and it is necessary to take into account the phonon-roton and roton-roton
interactions.

The roton part \( \kappa_r(T) \) of the thermal conductivity is proportional to the
average collision time \( \tau_r \). When \( \theta = 0 \), \( \tau_r \) is zero, and for small-angle scat-
tering \( \tau_r \) becomes very small. Since Eq. (5.10) is involved in the unknown
interaction potential constant \( V_{or} \) and we have only to know the magnitude of
the temperature dependence for \( \kappa_r \), there is no problem as to whether we take
maximum \( \tau_r \) or not. Taking \( \theta = \pi/2 \) and the numerical parameters in Table I,
\( \kappa_r(T) \) can be expressed as

\[
\kappa_r(T) = \frac{0.191 \times 10^{-66}}{|V_{or}|^{1/2}} \left[ \frac{1}{T} + 0.221 T + 0.728 + 4.743 \left( \frac{1}{T} + 0.362 \right) \right. \\
\left. \times \left\{ \frac{1 + 28.02 \left( \frac{3}{2} + \frac{4.12}{T} \right) T^{-32} e^{-\frac{4.12}{T}}}{1 + 4632.89 T^{-32} e^{-\frac{4.12}{T}}} \right\} \right] .
\] (5.1)

Figure 3 illustrates \( \kappa_r \) as a function of temperature. The coefficient in-
creases slowly as temperature decreases and is proportional to \( T^{-1} \).

The characteristic times which determine the coefficient \( \kappa_{ph} \) \( (T) \) are given
by Eqs. (3.24) - (3.26). \( \tau_{ph-r}^{-1} \) has the temperature dependence of \( T^{32} e^{-\Delta/k_B T} \),
which is one power lower than \( T^{32} e^{-\Delta/k_B T} \) in bulk liquid helium. This is due to dimen-
sionality, where \( \tau_{5PP}^{-1} \) has the temperature variation of \( T^{4} \), which is a lower
power than that of three dimensions. The inverse of \( \tau_{3PP} \) is proportional to
\( T^{4} \), which originates from the anomalous excitation spectrum. Figure 4 is the
temperature variation of characteristic times. \( \tau_{5PP}^{-1} \) is comparable with
\( \tau_{\text{ph}}^{-1} \) near about 0.8 K, and thus we can conclude that above 0.8 K the 5PP and
the scattering of phonons by rotons will mainly contribute to the thermal
conduction. Since 5PP appear in the inelastic collision process in the tem-
perature range of roton-roton collisions, we should not take into account this
contribution to \( \kappa_{\text{ph}}(T) \) below 0.8 K, and should consider only the phonon-roton
collision process. Therefore, in accordance with the regions of temperature,
we can express Eq. (3.31) as

\[
\kappa_{\text{ph}}(T) = \frac{1.803k_B^2 T^2}{\pi^2 C^2 \rho \tau_{\text{ph-r}} \left( C^2 - \frac{ST}{\rho_n} \right)} \tau_{\text{ph-r}} \left[ \frac{13.419 + 5.376 \tau_{\text{ph-r}}/\tau_{\text{5PP}}}{1 + 5.376 \tau_{\text{ph-r}}/\tau_{\text{5PP}}} \right]
\]

\( T > 0.8K \) \hspace{1cm} (5.2)

and

\[
\kappa_{\text{ph}}(T) = \frac{1.803k_B^2 T^2}{\pi^2 C^2} \left( C^2 - \frac{ST}{\rho_n} \right) \tau_{\text{ph-r}} \left[ 2.36 \times 10^{-11} \left( 1 - \frac{ST}{\rho_n C^2} \right) T^{-2/3} e^{\frac{4k_B T}{T}} \right], \hspace{0.5cm} T < 0.8K. \hspace{1cm} (5.3)
\]

Since the temperature-dependent term within the parenthesis of Eq. (5.3) is
much smaller than unity for temperatures below about 0.3 K, it can be neglected.
Then we have

\[
\kappa_{\text{ph}}(T) = 1.093 \times 10^{-7} T^{-5}, \hspace{0.5cm} T \leq 0.3K. \hspace{1cm} (5.4)
\]

In Fig. 5 the coefficient \( \kappa(T) \) is plotted as a function of temperature
based on Eqs. (5.2) - (5.4). As temperature decreases (< 0.8 K), Eqs. (5.3)
plays a dominant role and gives the exponential increase. At yet lower tempera-
tures (below about 0.3 K), Eq. (5.4) takes part in the thermal conductivity, and \( \kappa_{\text{ph}} \) increases rapidly and diverges as temperature tends to zero.

Comparison of Eq. (5.3) with Eq. (3.32) reveals that the second term in Eq. (3.32) has the same factor \( T^{-s} e^{1/kBT} \). This is due to the fact that \( T^{-s} \) and the thermodynamic functions are one power lower in temperature than those of three dimensions, and thus their ratios have the same temperature-dependent factor.

For viscosity we may give similar arguments as those for thermal conductivity. However, the main difference from thermal conduction is that the kinetic equation (Eq. (4.1)) does not vanish for a pure phonon gas near zero temperature. Therefore, we have treated separately the contribution for the pure phonon gas to viscosity (Eq. (4.25)).

Substitution of Eq. (2.35) in Eq. (4.9) and the choice of \( \theta = \pi / 2 \) gives the roton part of the first viscosity as

\[
\eta_r(T) = \frac{h^3 P_0^2}{32 \mu^2 |V_0|^2}, \quad (5.5)
\]

which is independent of temperature. Since Eq. (4.3) decreases exponentially with temperature and the mean free path of roton increases at about same rate, the viscosity becomes independent of temperature.

At temperatures about above 0.8 K, the main contribution is due to 5PP and the phonon-roton collision process, and thus Eq. (4.21) becomes

\[
\eta_{\text{ph}}(T) = \frac{7.212}{16\pi \hbar^2 C_0} (k_B T)^3 \tau_{\text{ph-r}} \left[ \frac{13.419 + 5.376 \tau_{\text{ph-r}} / \tau_{5\text{PP}}}{1 + 5.376 \tau_{\text{ph-r}} / \tau_{5\text{PP}}} \right], \quad (5.6)
\]

\[ T > 0.8K. \]
At temperatures below 0.8 K, we consider only the phonon-roton collision process and thus have

\[ \eta_{ph}(T) = \frac{2.645}{\pi \hbar^2 C_0} (k_B T)^3 \tau_{phr} \]

\[ = 2.17 \times 10^{-20} T^{-\frac{4\Delta}{E_0}} e^{\frac{4\Delta}{E_0}}. \]  

(5.7)

For temperatures below about 0.3 K, we have another temperature dependence given by Eq. (4.25):

\[ \eta_{ph}(T) = 5.92 \times 10^{-4} T^{-1}. \]  

(5.8)

Figure 6 illustrates the coefficient \( \eta_{ph}(T) \) of the first viscosity as a function of temperature based on Eq. (5.8). At temperatures below about 0.8 K, \( \eta_{ph} \) increases exponentially as temperature decreases. However, as temperature approaches absolute zero, the roton density becomes zero, and thus the contribution from the roton-phonon scattering to viscosity vanishes so that the main contribution comes from the 3PP. Therefore, the temperature dependence is changed from \( T^{-\frac{4\Delta}{E_0}} e^{\frac{4\Delta}{E_0}} \) to \( T^{-1} \). The coefficient increases slowly, and near zero temperature it increases very rapidly and finally diverges.

In conclusion, we remark that the behavior of the coefficients of the thermal conductivity and first viscosity are very much like that of the bulk case. At below 0.3 K, the contribution to the coefficient of first viscosity is due to the 3PP, which is shown to have a \( T^{-1} \) dependence.
Acknowledgments

The authors are very thankful to Professor J. S. Kang for a critical reading of the manuscript. This research was supported in part by a grant to Korea University from KOSEF under Contract No. 862-0203-011-2, and in part by the Office of Naval Research and Air Force Office of Scientific Research (AFSC), under Contract F49620-86-C-0009, with the Research Foundation of the State University of New York.
Appendix

Since the calculations for Eqs. (3.24)-(3.26) are very similar, we shall derive only Eq. (3.24). The collision integral (Eq. (3.20)) can be expressed as

$$J_{ph-r}(n) = N_r C \int \left[ (n' - n_0) - (n - n_0) \right] \, d\sigma.$$  \hspace{1cm} (A.1)

Making use of Eq. (3.14), Eq. (A.1) becomes

$$J_{ph-r}(n) = N_r C \int n_0 (n_0 + 1) \beta \frac{p_0}{k_B T} (\cos\theta' - \cos\theta) \, d\sigma.$$  \hspace{1cm} (A.2)

In Fig. 1 the relation between angles is given by

$$\cos\theta' - \cos\theta = \cos\theta \left[ \cos \psi - 1 + \tan \theta \sin \psi \right]$$  \hspace{1cm} (A.3)

Substituting Eqs. (2.25) and (A.3) in (A.2) and performing the integration over \( \psi \), we get

$$J_{ph-r}(n) = N_r C \cos \theta \left\{ -\beta \frac{p_0}{k_B T} \right\} n_0 (n_0 + 1) \frac{p_0^2 p^3}{8 \hbar^2 p^2 C^2} \times \left[ \frac{1}{4} + \frac{9}{32} \left( \frac{p_0}{\mu C} \right) + \frac{p_0 A}{\mu C} + 2A^2 \right].$$  \hspace{1cm} (A.4)

The collision integral may be written as

$$J_{pn-r}(n) = -\frac{n-n_0}{r_{ph}(p)}.$$  \hspace{1cm} (A.5)
To obtain the temperature dependence of $\tau_{\text{ph-r}}(T)$, we calculate the following integral:

$$\xi = \oint J_{\text{ph-r}}(n) \, dp \, \int \frac{\partial n}{\partial \epsilon} \, \epsilon^2 \, dp$$  \hspace{1cm} (A.6)

Performing the integrations over momentum space, we have

$$\oint J_{\text{ph-r}}(n) \, dp = \cos \theta \, \frac{\beta}{k_B T} \left\{ -\beta \, \frac{p_C}{k_B T} \right\} \frac{P_0^2}{8 \hbar^2 \rho^2 C^2} \, G\left( \frac{k_B T}{C} \right) \, 6! \xi(6), \hspace{1cm} (A.7)$$

$$\int \frac{\partial n}{\partial \epsilon} \, \epsilon^2 \, dp = -3! \xi(3) \, C \left( \frac{k_B T}{C} \right)^3 \hspace{1cm} (A.8)$$

where $G$ represents the bracket of the right-hand side in Eq. (A.4), and then Eq. (A.6) becomes

$$\xi = \cos \theta \, \frac{\beta}{k_B T} \, \frac{6! (6)}{3! (3)} \frac{P_0^2 k_B^3 T^3}{8 \hbar^2 \rho^2 C^2} \, G. \hspace{1cm} (A.9)$$

Substitution of Eqs. (A.5) and Eq. (3.14) in Eq. (A.6) and integration over momentum space gives Eq. (A.6) as

$$\xi = \beta \cos \theta / \tau_{\text{ph-r}}(T). \hspace{1cm} (A.10)$$

Comparing Eqs. (A.10) and (A.9), we obtain the characteristic time $\tau_{\text{ph-r}}(T)$:

$$\tau_{\text{ph-r}}^{-1}(T) = \frac{6! \xi(6)}{3! \xi(3)} \frac{N P_0^2 k_B^3 T^3}{8 \hbar^2 \rho^2 C^2} \left[ \frac{1}{4} + \frac{9}{32} \left( \frac{P_0}{\mu_C} \right)^2 + \frac{P_0 A^2}{\mu_C} + 2A^2 \right]. \hspace{1cm} (A.11)$$

In the case of the first phonon viscosity, we should replace Eq. (A.4) by Eq. (4.15). Through the same calculation we get
\[
\tau_{h^{-1}}(T) = \frac{6 \iota \sigma (6)}{3 \iota \sigma (3)} \frac{N_r P_0}{8 \pi R_4 C^4} \left\{ \frac{1}{2} + \frac{5}{32} \left( \frac{P_0}{\mu C} \right)^2 + \frac{3}{4} \frac{P_0 A}{\mu C} + 2A^2 \right\}. \quad (A.12)
\]
