Effect of Finite Size on Magnetoresistance

H.R. Lee, H.G. Oh and Thomas F. George

Finite size effects are studied for magnetoresistance in a disordered metallic system. Quantum corrections to the conductivity are strongly affected by the presence of an in-plane magnetic field in a thin film. They are also affected significantly by the boundaries of the finite quantum size. Expressions are obtained for the quantum correction to the conductivity due to both effects. The dephasing characteristic time scale due to the magnetic field is found by the exact eigenvalues of the system. One-, two- and three-dimensional results can be obtained with the proper limits. Some numerical results are presented for the given inelastic scattering length.

Abstract

Finite size effects are studied for magnetoresistance in a disordered metallic system. Quantum corrections to the conductivity are strongly affected by the presence of an in-plane magnetic field in a thin film. They are also affected significantly by the boundaries of the finite quantum size. Expressions are obtained for the quantum correction to the conductivity due to both effects. The dephasing characteristic time scale due to the magnetic field is found by the exact eigenvalues of the system. One-, two- and three-dimensional results can be obtained with the proper limits. Some numerical results are presented for the given inelastic scattering length.

PACS numbers: 72.15.Gd, 73.50.Dn, 73.60.Aq
I. Introduction

The effect of a magnetic field on electronic states has been studied extensively for disordered systems.\textsuperscript{1-3} The predictions of the anomalous magnetoresistance have been tested by several experiments on metal films\textsuperscript{4} and semiconductor structures.\textsuperscript{5} The resistance of thin films and wires has been studied in the presence of a longitudinal magnetic field,\textsuperscript{3} which is more effective than a field directed perpendicular to the film. In Ref. 3, the dimensions of the system are very small compared to the magnetic length because the magnetic field is treated as a small perturbation. Here perturbation theory yields the dephasing characteristic time $\tau_H = \frac{12a_H^2}{DW^2}$ for a square film or a wire of rectangular cross section, where $a_H$ is the magnetic length of a particle with charge $2e$, $D$ is the electron diffusion coefficient, and $W$ is the dimension of the system. Generally perturbation theory can be used when the condition $W \ll a_H$ holds. But, it is not appropriate to apply perturbation theory to the ground state, which is most important for corrections to the conductivity. The reason is explained later in this paper. Here we study the effect of the boundaries on the eigenvalues of the maximally crossed diagram in a thin film or wire with the longitudinal magnetic field by a numerical method. From the eigenvalues of the maximally crossed diagram, we obtain analytical expressions for quantum corrections to the conductivity of thin films and wires, which are given in Eqs. (13) and (14), respectively. Quantum corrections to the conductivity are calculated as a function of the normalized dimension ($W/a_H$) of the thin film or wire. Since a wide range of the normalized dimension $W/a_H$ is used in our calculations, the actual dimension $W$ of the system can range from
very small values to values which are larger than the magnetic length. We obtain the dephasing characteristic time $\tau_H = 24 a_H^2/DW^2$ as different from the result of the perturbation method in restricted geometries.

II. Theory

The quantum correction to the conductivity of non-interacting electrons weakly scattered by rigid random impurities is

$$\Delta \sigma(\omega \to 0) = - \frac{ss^2}{\pi \hbar} D\Gamma(\vec{r}, \vec{r}', \omega),$$  \hspace{1cm} (1)

where $s$ is spin degeneracy, and $\Gamma(\vec{r}, \vec{r}', \omega)$ is the vertex correction due to the sum of all the maximally crossed diagrams. In the absence of the magnetic field, the vertex part $\Gamma(\vec{r}, \vec{r}', \omega)$ is

$$\Gamma(\vec{r}, \vec{r}', \omega) = \frac{1}{\hbar} \sum_{\vec{q}} \frac{1}{D\vec{q}^2 + i\omega}. \hspace{1cm} (2)$$

This vertex part is strongly affected by the presence of an external magnetic field, because the symmetries inherent to the system are broken by the field. This has been studied in Ref. 1 in the coordinate representation through the equation

$$\hat{W}[D(-i\frac{\partial}{\partial \vec{r}} - \frac{2\pi}{\hbar} \vec{A}(\vec{r}))^2 + \frac{1}{\tau_{in}}] \Gamma(\vec{r}, \vec{r}') = \delta(\vec{r} - \vec{r}'),$$ \hspace{1cm} (3)
where \( \mathbf{A}(\mathbf{r}) \) is the magnetic vector potential, and \( -i\omega \) is replaced by the inelastic scattering time \( r_{in}^{-1} \) at finite temperature.\(^6\)

Now let us consider a thin film which has a thickness \( W \) under an in-plane magnetic field \( \mathbf{H} = (0,0,H_0) = \mathbf{\hat{v}} \times \mathbf{A} \). If we choose the Landau gauge \( \mathbf{A} = (0, xH_0, 0) \), the solution of Eq. (3) can be written as

\[
\Gamma(x,x') = \int \frac{dq_x dq_y}{(2\pi)^2} \sum_n \frac{\psi_{n,q_x}(x)\psi_{n,q_y}(x')}{D(q_x^2+E_n(q_y)) + \frac{1}{r_{in}}} .
\]

(4)

where \( \psi_{n,q_x}(x) \) and \( E_n(q_y) \) are the eigenfunctions and eigenvalues, respectively, of the equation

\[
- \frac{\partial^2}{\partial x^2} - (q_y - \frac{2eH_0}{\hbar c} x)^2 \psi_{n,q_y}(x) = E_n(q_y)\psi_{n,q_y}(x)
\]

within the film. The above equation can be written as

\[
- \frac{\partial^2}{\partial x^2} - \frac{(x-x_0)^2}{a_H^2} \psi_{n,q_y}(x) = E_n(q_y)\psi_{n,q_y}(x)
\]

(6)

where \( a_H = \sqrt{\frac{eH_0}{2\hbar c}} \) is the magnetic length of a doubly-charged particle and \( x_0 \) is related to the wavevector \( q_y \) by the expression \( x_0 = a_H^2 q_y \). Now if we introduce the normalized coordinate \( \xi = \sqrt{2x/a_H} \), Eq. (6) can be transformed into the well-known Weber equation.
\[
\frac{\partial^2}{\partial \xi^2} - \frac{1}{4}(\xi - \xi_0)^2 + (\nu_n + \frac{1}{2}) \psi_{n', q_y}(\xi) = 0 ,
\]

where \(\xi_0\) is related to the wavevector \(q_y\) by \(\xi_0 = \sqrt{2a_Hq_y}\). We construct the general solutions of Eq. (7) as

\[
\psi_{n', q_y}(\xi) = A D_{\nu_n}(\xi) + B D_{\nu_n}(-\xi) ,
\]

where \(A\) and \(B\) are the normalization constants and \(D_m(z)\) is the Weber function given by

\[
D_m(z) = z^{m/2} \exp\left(\frac{z^2}{4}\right) \left[\frac{\sqrt{\pi}}{\Gamma\left(-\frac{m+1}{2}\right)} \mathbf{1}_F(\frac{-m}{2}; \frac{1}{2}; \frac{1}{2}z^2) - \frac{\sqrt{2\pi}z}{\Gamma\left(-\frac{m}{2}\right)} \mathbf{1}_F\left(-\frac{m+1}{2}; \frac{1}{2}; \frac{1}{2}z^2\right)\right] .
\]

Here \(\mathbf{1}_F(a;b;x)\) is the confluent hypergeometric function and \(\Gamma(z)\) is the gamma function. The eigenvalues are given by

\[
E_n(q_y) = \frac{2}{a_H} \left(\nu_n + \frac{1}{2}\right) .
\]

III. Results and Discussion

Equation (7) yields the discrete spectrum of eigenvalues for each value of the continuously varying wavevector \(q_y\). If there are no boundaries, both
the eigenvalues and eigenvectors become identical to the solutions describing the unrestricted motion of free particles in the magnetic field. The eigenvalues of Eq. (7) can be determined if the precise form of the confining potential is given. The results are shown in Fig. 1 for normalized dimensions of the sample $\sqrt{2W/a_H} = 1.0$ with the boundaries of an infinite confining potential barrier, given by

$$\frac{\partial \psi_{n,q_y}(x)}{\partial x} \bigg|_{x=\pm W/2} = 0$$ .

(11)

Since each mode in Fig. 1 shows parabolic-like behavior as a function of the wavevector $q_y$, we may write the eigenvalues in a parabolic approximation as

$$E_n(q_y) = \frac{\Delta_n}{a_H^2} + C_n q_y^2$$ .

(12)

where $\Delta_n$ is the y-intercept ($q_y=0$) and $C_n$ represents the coefficient of the quadratic term in each mode.

For a thin film, when we substitute Eq. (12) into (4) and integrate over $q_y$ and $q_z$, we obtain

$$\Delta \sigma = \frac{e^2}{2\pi^2 a_H^2} \sum_n \frac{1}{C_n} \ln \left( \frac{1/k_{1y}^2 + 1/k_{1n}^2}{\Delta_n/a_H^2 + 1/k_{1n}^2} \right)$$ .

(13)
where the elastic diffusion length $l_{el} = \sqrt{D_0}$ is used for the upper limit of the integration. The quantum corrections to the conductivity of rectangular wires with transverse dimensions small in comparison with $l_{in}$ can be obtained in the same way and are given by

$$\Delta\sigma = -\frac{2e^2}{\pi^2nH} \sum \frac{1}{c_n \left( \frac{l_{el}^2}{l_{in}^2} + \frac{\Delta_n}{a^2_H} \right)} \tan^{-1} \left( \frac{c_n \left( \frac{l_{el}^2}{l_{in}^2} + \frac{\Delta_n}{a^2_H} \right)}{1/l_{in}^2 + \Delta_n/a^2_H} \right). \quad (14)$$

Numerical results for magnetoconductivity in thin films and the magnetoconductivity per unit length in rectangular wires are presented in Figs. 2 and 3, respectively, for various values of the ratio $W/l_{in}$. In each graph we have used the unitless quantity $\xi = \sqrt{W/a_H}$ in the x-direction, and the dimensions of the sample are normalized to the inelastic scattering length $l_{in}$. Thus x-coordinates of the graphs are proportional to $\sqrt{n_0}$ for the given sample size. The effect of a magnetic field becomes more prominent on the quantum interference (weak localization) at small values of $W/l_{in}$, that is, at small dimensions of the sample or at large values of $l_{in}$ (low temperature) for the given system.

The values $\Delta_0$ and $C_0$ of the lowest-lying state (n=0), which is the most important for quantum corrections to the conductivity, are given in Table I for comparison with those in the absence of a magnetic field.

Without the magnetic field, $E_n^0(q_y)$ may be written in a similar form as
\[ E_n^0(q_y) = \left( \frac{n\pi}{W} \right)^2 + q_y^2 \quad \text{(15)} \]

where \( n = 0, \pm 1, \pm 2, \ldots \). When the condition \( W \ll a_H \) holds, Table I shows \( \Delta_0/a_H^2 = W^2/24a_H^4 \) for the ground state, whereas perturbation theory yields \( W^2/12a_H^4 \). As we can see clearly from Eq. (5) that perturbation theory can not be applied for small values of \( q_y = 0 \), which has the most significant contributions to the corrections to the conductivity. Thus the characteristic time scale must be \( r_H = 24a_H^2/DW^2 \) in magnetoconductivity, which is given by

\[ \sigma(H) - \sigma(0) = -\frac{e^2}{2\pi^2\hbar} \ln\left( \frac{r_H}{r_0} + 1 \right) \quad \text{(16)} \]

for a thin film, and the quantum corrections to the conductivity per unit length are given by

\[ \Delta\sigma(H) = -\frac{e^2}{\pi\hbar} \left( \frac{1}{D_{\text{in}}} + \frac{1}{D_{\text{H}}} \right) \quad \text{(17)} \]

for a wire of rectangular cross section.

If the other condition \( W \gg a_H \) holds, the eigenvalues are divided into two parts: (1) the surface part, that is, those states whose orbit is affected by one wall of the sample, and (2) the bulk orbits which are not affected by the boundaries of the sample. The surface part always has an almost constant contribution to the conductivity, whereas the bulk part is proportional to the sample width \( W \) due to many degenerate states in each
level. Thus, we can recover the results of the bulk limit given in Ref. 1 (cf. the values in Table I).
