Abstract

The paper studies the plate bending problem with hard and soft simple support. It shows that in case of hard support, the plate paradox that is known to occur in the Kirchhoff model is also present in the three-dimensional model and the Reissner-Mindlin model. The paradox consists of the fact that on a sequence of convex polygonal domains converging to a circle, the solutions of the corresponding plate bending problems with a fixed uniform load do not converge to the solution of the limit problem. The paper also shows that the paradox is not present when soft simple support is assumed. Some practical aspects are briefly discussed.
1. Introduction.

The Kirchhoff model of a plate is usually accepted as a good approximation to the three-dimensional model for thin plates. In the case of simply supported polygonal plates, however, the Kirchhoff model is known to suffer from unphysical phenomena that can lead to a large error of the model in some situations. In particular, the following paradox, referred to as the plate paradox below, occurs [2], [4]: Consider a sequence \( \{ \omega_n \} \) of convex polygonal domains approaching a circle. For each \( n \) let \( \omega_n \) be the transverse deflection corresponding to the Kirchhoff model of the plate bending problem where the plate occupies the region \( \omega_n \) is simply supported on \( \partial \omega_n \) and is subject to a uniform load \( p(x) \equiv 1 \). Further, let \( \omega_c \) be the solution to the limit problem, i.e., that on the circle. Then as \( n \to \infty \), the sequence \( \{ \omega_n \} \) converges pointwise, but the limit \( \omega_\infty \) is different from \( \omega_c \). For example, at the center of the circle the error of \( \omega_\infty \) is about 40%. Some other related plate paradoxes are given by Mazja [14], [14]. Practical implications occur for example in the finite element method when the domain is approximated by a polygon with the side length \( h \to 0 \). For further aspects see also [8], [18], [21], [23], [25].

It is often assumed that the plate paradox is caused by the assumption of vanishing vertical shear strains that is implicit in the Kirchhoff model. This was supported e.g. by a note (see [3]) that the paradox is not present when the Reissner-Mindlin model instead of the Kirchhoff model is used. The aim of this paper is to locate the source of the paradox more precisely: We show that it is the way the boundary conditions are imposed in the Kirchhoff model that causes the paradox, and not the overall assumption of vanishing shear strains.

In the three-dimensional model of the plate, the boundary condition of
simple support is imposed typically by requiring that the vertical component of the displacement (or at least its average in the vertical direction) vanishes on the edge of the plate. On the other hand, in the Kirchhoff model one effectively imposes the more restrictive condition that all tangential displacements must vanish on the edge. Of course, it is possible to impose such "hard" boundary conditions also in other plate models, e.g. in the Reissner-Mindlin model (cf. [22]) or in the three-dimensional model itself. We show that in such a case, the plate paradox occurs in both the Reissner-Mindlin model and in the three-dimensional model. On the other hand, we also show that the paradox does not occur in these models in case of "soft" support where only the vertical displacements are restricted on the edge of the plate. Hence, we are led to the conclusion that the paradox is caused by the hard boundary conditions which are intrinsic for the Kirchhoff model.

Our results are based upon energy estimates relating the three-dimensional model and the Reissner-Mindlin model to the Kirchhoff model. Such estimates can be derived by combining the energy and complementary energy principles associated to the plate bending problem, and they were in fact applied early by Morgenstern [16], [17], to prove that the Kirchhoff model is the correct asymptotic limit of the three-dimensional model as the thickness of the plate tends to zero. Although the assumption of a smooth domain is implicit in Morgenstern's work, one can easily extend the analysis techniques of [16] to more general situations. In particular, we show here that in a sequence of convex polygonal domains converging to a circle, the relative error of the Kirchhoff model, when compared to the three-dimensional model with hard support, is uniformly of order $O(h^{1/2})$ in the energy norm, where $h$ is the thickness of the plate. Moreover, we show by similar techniques that the gap between Reissner-Mindlin and Kirchhoff models is uniformly of
order \( O(h) \) under the same assumptions. Finally, we show that on a smooth domain, the three models are at most \( O(h^{1/2}) \) apart. Hence we conclude that the plate paradox must occur in the hard-support models if \( h \) is fixed and sufficiently small.

Let us mention that our results are in parallel with recent benchmark calculations [7]. These calculations confirm in particular that the error of the Kirchhoff model with respect to the three-dimensional model is primarily due to the assumed hard boundary conditions on simply supported polygonal plates. For example, in case of a uniformly loaded square plate of thickness \( h = \text{side length}/100 \), the relative error of the Kirchhoff model in energy norm is \(-11\%\) when compared to the three-dimensional model with soft support and \(-2\%\) when compared to the hard-support model [7]. This example also shows that the error of the Kirchhoff model may be quite large even for relatively thin plates of simple shape.

The above results show that imposing various boundary conditions that are seemingly close, such as the hard and soft simple support, can influence the solution in the entire domain and not only in the boundary layer. Very likely such effects occur also for other boundary conditions for both plates and shells. Therefore, since any boundary condition is anyway an idealization of reality, finding the "correct" boundary conditions is an important and sometimes difficult part of building a dimensionally reduced model. For example, it can happen that both the soft and hard simple support are poor approximations of the real "simple" support.

The plan of the paper is as follows. Section 2 gives the preliminaries and basic formulations of the plate problems. Section 3 elaborates on the variational formulations of the plate problems and presents various energy estimates. Section 4 addresses the problem of the plate paradox. Finally,
Appendices A, B, C present some auxiliary results needed in Sections 3 and 4.

2. Preliminaries.

Consider an elastic plate of thickness $h$ which occupies the region $\Omega = \omega x(-h/2,h/2)$ where $\omega \in \mathbb{R}^2$ is a Lipschitz bounded domain. We assume that the plate is subject to given normal tractions $p$ (i.e., the load) on $\partial \omega x(-h/2)$ and $\partial \omega x(h/2)$ and that it is simply supported on $\partial \omega x(-h/2,h/2)$ in such a way that if $u = (u_1, u_2, u_3)$ is the displacement field, then

\begin{equation}
(2.1)\quad u_3(x) = 0, \quad x \in \partial \omega x(-h/2,h/2)
\end{equation}

and the other two conditions are natural boundary conditions describing homogeneous (zero) components of tractions. This condition will be called later the soft simple support. Assuming for the moment that no other geometric boundary conditions other than (2.1) are imposed, the plate bending problem can be formulated as: Find the displacement field $u_0$ which minimizes the quadratic functional of the total energy

\begin{equation}
(2.2)\quad F(u) = \frac{1}{2} \int_{\Omega} \left\{ \lambda (\text{div} \ u)^2 + \mu \sum_{i,j=1}^{3} [\varepsilon_{ij}(u)]^2 \right\} dx_1 dx_2 dx_3
- \int_{\omega} p \frac{1}{2} u_3(\cdot, \frac{h}{2}) + u_3(\cdot, -\frac{h}{2}) dx_1 dx_2
\end{equation}

in the Sobolev space $[H^1(\Omega)]^3$ under the boundary condition (2.1). Here

$\varepsilon = \{\varepsilon_{ij}\}_{1,j=1}^3, \quad \varepsilon_{ij} = \frac{1}{2} \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right)$ is the strain tensor and $\lambda$ and $\mu$ are the Lamé coefficients of the material, i.e.,

$$\lambda = \frac{E\nu}{(1+\nu)(1-2\nu)}, \quad \mu = \frac{E}{1+\nu}.$$
where $E$ is the Young modulus and $\nu$ is the Poisson ratio, $0 \leq \nu \leq 1/2$. We also assumed that the surface traction $p$ is symmetrically distributed with regard to the planar surfaces of the plate, i.e., we consider a pure bending problem.

So far we have assumed a special model of the simple support based on simple geometric constraint (2.1). Of course, there are many other possibilities. We will discuss later another model - the hard simple support and discuss the effects of these models of the simple support on the solution.

It is well known that if $h/diam(\omega)$ is small, the three-dimensional plate bending problem can be formulated in various dimensionally reduced forms, see e.g. [1], [11], [22]. We consider here two representatives of such formulations which are used in practice; the Kirchhoff model and the Reissner-Mindlin model (cf. [22] and references therein).

In general when $w$ is fixed and $h \rightarrow 0$ then the three-dimensional formulation and the dimensionally reduced models converge to the same limit, provided that the load $p$ is appropriately scaled (see below). Hence for sufficiently thin plates the models give practically the same solutions. However, as will be seen later, what is "sufficiently thin" can depend strongly on $w$, i.e., the convergence can be very slow in some situations.

In the Kirchhoff model, we approximate the three-dimensional solution as

$$w_0(x_1, x_2, x_3) \approx -x_3 \frac{\partial w_K}{\partial x_1}(x_1, x_2), x_3 \frac{\partial w_K}{\partial x_2}(x_1, x_2), w_K(x_1, x_2))$$

where $w_K$ minimizes the energy

$$(2.3) \quad F_K(\omega) = \frac{1}{2} \int_\omega (\nu(\Delta w)^2 + (1-\nu) \sum_{1,j=1}^2 \left( \frac{\partial^2 w}{\partial x_1 \partial x_j} \right)^2 dx_1 dx_2 - \int_\omega f w dx_1 dx_2$$

in the Sobolev space $H^2(\omega)$ under the boundary condition
Here $f$ is related to $p$ as

$$f = \frac{p}{D}, \quad D = \frac{Eh^3}{12(1-\nu^2)}$$

When comparing different plate models with fixed $w$ and variable $h$ we will assume below that $f$ (and not $p$) is fixed. This assures that the different models have the same (non-trivial) limit as $h \to 0$. For example, defining the average transverse deflection in the three-dimensional model as

$$w_0 = \frac{1}{h} \int_{-h/2}^{h/2} u_3(x_1, x_2, x_3) dx_3,$$

one can show (under fairly general assumptions on $w$, see [10], [11], [16], [17] and section 3 below) that $\|w_0 - w_0^L\|_{L^2(\omega)} \to 0$ as $h \to 0$.

In the Reissner-Mindlin model, one approximates $u_0$ by

$$u_0(x_1, x_2, x_3) \approx (-x_3 \theta_R(x_1, x_2), -x_3 \theta_R(x_1, x_2), w_R(x_1, x_2))$$

where $(w_R, \theta_R)$ minimizes the energy

$$F_R(w, \theta) = \frac{1}{2} \int_{\omega} (\nu(\nabla \theta)^2 + (1-\nu) \sum_{1, j=1}^{2} [e_{ij}(\theta)]^2) dx_1 dx_2$$

$$+ \frac{1}{2} \frac{\kappa}{h^2} \int_{\omega} |\theta - \nabla \omega|^2 dx_1 dx_2 - \int_{\omega} f dx_1 dx_2$$

in the Sobolev space $[H^1(\omega)]^3$ under the boundary condition (2.4). Here $\kappa = 6(1-\nu)\kappa_0$ where $\kappa_0 = O(1)$ is an additional shear correction factor which may take various values in practice.

We point out that the Kirchhoff approximation to $u_0$ satisfies in addition to (2.1) the boundary condition

\[ (2.4) \quad w = 0 \text{ on } \partial \omega. \]
(2.7) \[(u_1 t_1 + u_2 t_2)(x) = 0, \quad x \in \partial \omega (-h/2, h/2),\]

where \( t = (t_1, t_2) \) denotes the tangent to \( \partial \omega \). This suggests that one should also consider the original plate bending problem under such more restrictive geometric boundary conditions. Below we will refer to the boundary conditions (2.1), (2.7) and their counterpart in the Reissner-Mindlin model, i.e., (2.4) together with

(2.8) \[\theta_1 t_1 + \omega_2 t_2 = 0 \quad \text{on} \quad \partial \omega\]

as the hard simple support in contrast to the conditions (2.1), (2.4) which will be labeled as soft simple support. Hence when using the Kirchhoff model we have in mind the hard (and not soft) simple support. We will see later that the incapability of the Kirchhoff model to represent soft simple support can be a severe deficiency of the model on polygonal domains.

3. **Variational formulations of the plate bending problem. Energy estimates.**

In the first three subsections below and in the related Appendix A, we summarize first some basic characteristics of variational formalisms and energy principles associated to the plate bending problem in its various forms. These results are basically known, but we present them here for the reader's convenience. In subsection 3.4 we prove some energy estimates relating the Kirchhoff model to both the Reissner-Mindlin model and the three-dimensional model, using the results of the previous subsections.

We assume that the plate occupies the region \( \Omega = \omega (-h/2, h/2) \) where \( \omega \) is a Lipschitz bounded domain. Our particular interest is in the cases where \( \omega \) is either a convex polygon or a smooth domain.
We denote by $H^s(\omega)$, resp. $H^s(\Omega)$, the usual Sobolev spaces with index $s > 0$. The seminorm and norm of the spaces $[H^s(\omega)]^k$ or $[H^s(\omega)]^k$ are denoted by $| \cdot |_{s, \omega}$ and $\| \cdot \|_{s, \omega}$, resp. $| \cdot |_{s, \Omega}$ and $\| \cdot \|_{s, \Omega}$. By $(\cdot, \cdot)$ we mean the inner product of $[L_2(\omega)]^k$ or $[L_2(\Omega)]^k$, and by $\langle \cdot, \cdot \rangle$ the pairing of a space and its dual. The dual space of $H_0^1(\omega)$ will be needed often below and is denoted by $H^{-1}(\omega)$.

3.1. The three-dimensional model.

Let us denote by $N$ the space of horizontal rigid displacements of the plate:

$$N = \{(a_1 x_1 + a_3 x_2, a_2 x_2 - a_3 x_1, 0), \ a_i \in \mathbb{R}, \ i = 1, 2, 3\}.$$

We define the space of (geometrically) admissible displacements in case of soft simple support as

$$(3.1a) \ U = \{u \in [H^1(\Omega)]^3 : u_3 = 0 \text{ on } \partial \Omega (\pm h/2, h/2), \ (u, v) = 0 \ \forall \ v \in N\}$$

and in case of hard simple support, as

$$(3.1b) \ U = \{u \in [H^1(\Omega)]^3 : u_3 = t_1 u_1 + t_2 u_2 = 0 \text{ on } \partial \Omega (\pm h/2, h/2), \ (u, v) = 0 \ \forall \ v \in N\}.$$ 

(For simplicity, we remove here all the horizontal rigid displacements also in case of hard support.) We let further $\mathcal{H}$ stand for the space of stress or strain tensors defined as

$$\mathcal{H} = \{\varepsilon = (\varepsilon_{ij})_{i,j=1}^3 : \varepsilon_{ij} \in L_2(\Omega), \ \varepsilon_{ij} = \varepsilon_{ji}\},$$

and introduce a linear mapping $S : \mathcal{H} \to \mathcal{H}$ representing a scaled stress-strain relationship of a linear elastic material.
(S\tau)_{1,j} = D^{-1}[\lambda \text{tr}(\tau)\delta_{1,j} + \mu \tau_{1,j}],

where \( \lambda \) and \( \mu \) are the Lamé coefficients and the scaling factor \( D \) is as in (2.5). Then \( S \) is one-to-one and

\[
(S^{-1}\tau)_{1,j} = \frac{D}{E}[(1+\nu)\tau_{1,j} - \nu \text{tr}(\tau)\delta_{1,j}].
\]

Moreover, \( S \) and \( S^{-1} \) are self-adjoint if \( H \) is supplied with the natural inner product

\[
(\sigma,\tau)_H = \sum_{i,j=1}^{3} (\sigma_{ij},\tau_{ij}).
\]

Let us further define the bilinear forms

\[
A(u,v) = (\varepsilon(u),\varepsilon(v))_H, \quad u,v \in U,
\]

and

\[
B(\sigma,\tau) = (\sigma, S^{-1}\tau)_H, \quad \sigma,\tau \in H,
\]

and the linear functional

\[
Q(v) = \frac{1}{2} \int_{\omega} f(v_3(\cdot,-h/2) + v_3(\cdot,h/2)) dx_1 dx_2,
\]

where it is assumed that \( f \in L^2(\omega) \), to imply that \( Q \) is a bounded linear functional on \( U \) (by standard trace inequalities). In the above notation, the energy principle states that the displacement field \( u_0 \) due to the load \( f = Dp \in L^2(\omega) \) is determined as the solution to the minimization problem: Find \( u_0 \in U \) which minimizes in \( U \) the functional

\[
\mathcal{F}(u) = \frac{1}{2} A(u,u) - Q(u).
\]

The existence and uniqueness of \( u_0 \) is due to the following coercivity inequality known as the Korn inequality (cf. [19]).
Lemma 3.1. If $U$ is defined by (3.1a), there is a positive constant $c$ such that

$$\mathcal{A}(u, u) \geq c\|u\|_{L^2, \Omega}^2, \quad u \in U.$$  \hfill \Box$$

We point out that the constant in (3.3) depends on $\omega$ (and $h$), though it is positive for any given Lipschitz domain. In Appendix B we show that the constant in (3.3) remains uniformly positive over a certain family of domains, a result needed in Section 5 below.

Given $f$ and the corresponding displacement field $u_0$, let $\sigma_0 = Su_0$ be the corresponding (scaled) stress field. The pair $(u, \sigma) = (u_0, \sigma_0)$ is then the solution to the variational problem: Find $(u, \sigma) \in U \times \mathcal{H}$ such that

$$(3.4a) \quad \mathcal{B}(\sigma, \tau) - \langle \varepsilon(u), \tau \rangle_{\mathcal{H}} = 0, \quad \tau \in \mathcal{H},$$

$$(3.4b) \quad \langle \sigma, \varepsilon(\varphi) \rangle = Q(\varphi), \quad \varphi \in U.$$  

It can be easily verified following [5], [9] (see Appendix A), that the solution to (3.3) exists and is unique.

We mention finally that according to the complementary energy principle, $\sigma_0$ is found alternatively as the solution to the minimization problem [19]: Find $\sigma_0 \in \mathcal{H}$ that minimizes in $\mathcal{H}$ the functional

$$\mathcal{F}(\sigma) = \frac{1}{2} \mathcal{B}(\sigma, \sigma)$$

under the constraint (3.4b).

In Section 4 below we need the following corollary of the two energy principles (cf. [16]).

Lemma 3.2. For any $(u, \sigma) \in U \times \mathcal{H}$ such that $\sigma$ satisfies (3.4b), the following identity holds:
\[
\frac{1}{2} \mathcal{A}(u_0 - u, u_0 - u) + \frac{1}{2} \mathcal{B}(\sigma_0 - \tau, \sigma_0 - \tau) = \mathcal{F}(u) + \mathcal{G}(\sigma).
\]

**Proof.** It follows from the energy principle that

\[\mathcal{A}(u_0, v) = Q(v), \quad \forall v \in U,\]

and from the complementary energy principle that

\[\mathcal{B}(\sigma_0, \tau) = 0, \quad \tau \in \mathcal{K} : (\tau, \varepsilon, (\nu))_{\mathcal{K}} = Q(\nu), \quad \forall \nu \in U.\]

Therefore in particular, \(\mathcal{A}(u_0, u) = Q(u)\) and \(\mathcal{B}(\sigma_0, \sigma) = \mathcal{B}(\sigma_0, \sigma_0)\), and hence

\[
\frac{1}{2} \mathcal{A}(u_0 - u, u_0 - u) + \frac{1}{2} \mathcal{B}(\sigma_0 - \tau, \sigma_0 - \tau) = \left[ \frac{1}{2} \mathcal{A}(u_0, u) - \mathcal{A}(u_0, u) + \frac{1}{2} \mathcal{B}(\sigma_0, \sigma) \right] \\
+ \left[ \frac{1}{2} \mathcal{A}(u_0, u_0) + \frac{1}{2} \mathcal{B}(\sigma_0, \sigma_0) - \mathcal{B}(\sigma_0, \sigma) \right] \\
= \mathcal{F}(u) + \mathcal{G}(\sigma).
\]

3.2. The Reissner-Mindlin model.

In the Reissner-Mindlin model geometrically admissible displacements \((w, \theta)\) span the space \(H^1_0(\omega) \times V\), where either

\[(3.5a) \quad V = [H^1(\omega)]^2\]

or

\[(3.5b) \quad V = \{ \theta \in [H^1(\omega)]^2 : t_1 \theta_1 + t_2 \theta_2 = 0 \text{ on } \partial \omega \}\]

corresponding to soft and hard boundary conditions, respectively. We let \(\mathcal{K}\) stand for the space of momentum and curvature tensors:

\[\mathcal{K} = \{ m = (m_1, m_2)_{j=1}^2, \ m_1, m_2 \in L^2(\omega), \ m_{12} = m_{21} \}.\]
and supply $X$ with the natural inner product

$$(m,k)_X = \sum_{i,j=1}^{2} (m_{ij}, k_{ij}).$$

Further, we introduce the linear mapping $T : X \rightarrow X$ as defined by

$$(Tk)_{1j} = \nu \operatorname{Tr}(k) \delta_{1j} + (1-\nu)k_{1j}, \quad k \in X.$$

The inverse of $T$ is given by

$$(T^{-1}k)_{1j} = \frac{1}{1-\nu} k_{1j} - \frac{\nu}{1+\nu} \operatorname{Tr}(k) \delta_{1j}.$$

and obviously $T$ and $T^{-1}$ are self-adjoint.

We introduce finally the bilinear forms

$$A_R(w, \theta; z, \varphi) = (\epsilon(\theta), T\epsilon(\varphi)) + (\kappa/h^2) (\theta - \nabla w, \varphi - \nabla z), \quad w, z \in H^1_0(\omega), \quad \theta, \varphi \in V,$$

and

$$B_R(m, \gamma; k, \zeta) = (m, T^{-1}k), \quad (h^2/\kappa) (\gamma, \zeta), \quad m, k \in X; \quad \gamma, \zeta \in [L^2(\omega)]^2,$$

where $\epsilon_i = (\epsilon_{ij}(\theta))_{i,j=1}^{2}$ and $\kappa$ are as in (2.6).

In the above notation, the Reissner-Mindlin formulation of the plate bending problem, as stated according to the energy principle, is to find the pair $(w_R, \theta_R) \in H^1_0(\omega) \times V$ that minimizes in $H^1_0(\omega) \times V$ the functional

$$\mathcal{F}_R(w, \theta) = \frac{1}{2} A_R(w, \theta; w, \theta) - \langle f, w \rangle$$

for a given $f \in H^{-1}(\omega)$.

The existence and uniqueness of $(w_R, \theta_R)$ is the consequence of the following lemma, which is proved in Appendix B in a bit more general form (see Lemma B.2 of Appendix B.)

**Lemma 3.3.** There is a positive constant $c$ such that
\[(c(\theta), Tc(\theta))_X + \|\theta - \varphi w\|_0^2, \omega \geq c(\|\theta\|_{H^1_1}^2, \|w\|_{H^1_1}^2), \theta \in H^1(\omega), w \in H^1_0(\omega). \]

**Remark 3.1.** Regarding the validity of Lemma 3.3 uniformly over a sequence of domains, see Appendix B. (Such a result is needed in Section 5 below.)

The analogy of the variational formulation (3.4) is stated for the Reissner-Mindlin model as: Find \((w, \theta, m, \gamma) \in H^1_0(\omega) \times \mathcal{V} \times [L^2_2(\omega)]^2\) such that:

\begin{align*}
(3.7a) & \quad (m, T^{-1}_R k)_X - (c(\theta), k)_X = 0, \quad k \in \mathcal{K}, \\
(3.7b) & \quad (h^2/\kappa)(\gamma, \zeta) - (\theta - \varphi w, \zeta)_X = 0, \quad \zeta \in [L^2_2(\omega)]^2, \\
(3.7c) & \quad (m, c(\varphi))_X + (\gamma, \varphi)_X = 0, \quad \varphi \in \mathcal{V}, \\
(3.7d) & \quad -(\gamma, \varphi z) = <f, z>, \quad z \in H^1_0(\omega).
\end{align*}

The (unique, see Appendix A) solution to this problem is \((w_R, \theta_R, m_R, \gamma_R)_R\), where \(m_R = Tc(\theta_R)\) and \(m_R = (\kappa/h^2)(\theta - \varphi w)_R\) have the physical meaning of momentum and (vertical) shear stress field, respectively, both being scaled by a factor \(D^{-1}\).

We note finally that the pair \((m_R, \gamma_R)\) can be obtained alternatively as the solution to the following minimization problem (the complementary energy principle): Find \((m_R, \gamma_R) \in \mathcal{K} \times [L^2_2(\omega)]^2\) which minimizes in \(\mathcal{K} \times [L^2_2(\omega)]^2\) the functional

\[
\mathcal{Y}_R(m, \gamma) = \frac{1}{2} R(m, \gamma; m, \gamma)
\]

under the constraints (3.7c) and (3.7d).

Upon combining the two energy principles we obtain in analogy with Lemma 3.2 the following:

**Lemma 3.4.** For any \((w, \theta) \in H^1_0(\omega) \times \mathcal{V}\) and for any \((m, \gamma) \in \mathcal{K} \times [L^2_2(\omega)]^2\) sa
fying (3.7c) and (3.7d) the following identity holds:

\[
\frac{1}{2} R(\omega, \theta, \omega; \gamma) = \frac{1}{2} R(\omega, \theta, \omega; \gamma) + \frac{1}{2} R(\omega, \theta, \omega; \gamma) = R(\omega, \theta) + R(\omega, \theta).
\]

3.3. The Kirchhoff model.

Upon introducing the space

\[ W = \{ z \in H^2(\omega) : z = 0 \text{ on } \partial \omega \}, \]

the plate bending problem according to the Kirchhoff model is formulated as:

Given \( f \in W' \) (dual space of \( W \)), find \( w_K \in W \) which minimizes in \( W \) the energy functional

\[
R_K(w) = \frac{1}{2} \langle e(\nabla w), T(\nabla w) \rangle_{\mathcal{X}} - \langle f, w \rangle,
\]

where \( T \) and \( \langle \cdot, \cdot \rangle_{\mathcal{X}} \) are the same as in the Reissner-Mindlin model. The existence and uniqueness of \( w_K \) in the consequence of the coercivity inequality

\[
\langle e(\nabla w), T(\nabla w) \rangle_{\mathcal{X}} \geq C \| w \|^2_{L^2}, \quad w \in W,
\]

which itself is an easy consequence of Lemma 3.3. Note that \( w_K \) is uniquely defined in particular if \( f \in H^{-1}(\omega) \), and note also that the pair \( (w_K, \theta_K) \), where \( \theta_K = \nabla w_K \), minimizes the Reissner functional \( R \) over the subspace \( Z \subset H^1_0(\omega) \times V \) defined by

\[ Z = \{ (w, \theta) \in W \times V : \theta = \nabla w \}. \]

For the Kirchhoff model, the analogy of the mixed variational formulation (3.7) is the following: Given \( f \in W' \), find \( (w, \theta, m, \gamma) \in W \times V \times V' \) (where \( V' \) is the dual space of \( V \)) such that

\[
(3.8a) \quad \langle m, T^{-1} \rangle_{\mathcal{X}} - \langle e(\theta), k \rangle_{\mathcal{X}} = 0, \quad k \in X.
\]
(3.8b) \[ \langle \theta - \psi, \zeta \rangle = 0, \quad \zeta \in V' \]

(3.8c) \[ (m, \varepsilon(\varphi))_K + \langle \gamma, \varphi \rangle = 0, \quad \varphi \in V \]

(3.8d) \[-\langle \gamma, \psi \rangle = \langle f, z \rangle, \quad z \in W.\]

**Lemma 3.5.** The variational problem (3.8) is well-posed and the unique solution is \((w, \theta, m, \gamma) = (w_K, \theta_K, m_K, \gamma_K)\) where \(\theta_K = \nabla w_K\), \(m_K = T\varepsilon(\theta_K)\) and \(\gamma_K\) is defined by (3.8c), i.e.,

(3.9) \[ \langle \gamma_K, \varphi \rangle = -(m_K, \varepsilon(\varphi))_K, \quad \varphi \in V.\]

**Proof.** If \((w, \theta, m, \gamma) = (w_K, \theta_K, m_K, \gamma_K)\), equations (3.8a,b,c) hold trivially. Moreover, since \(w_K\) minimizes \(\gamma_K\) in \(W\), one has \(m_K, \varepsilon(\psi)\) \(K = (\varepsilon(\nabla w_K), T\varepsilon(\nabla z))_K = \langle f, z \rangle \quad \forall \quad z \in W\), so by (3.9), (3.8d) holds as well. The well-posedness is proved in Appendix A.

**Remark 3.2.** Note that although \(w_K, \theta_K\) and \(m_K\) obviously do not depend on the way the space \(V\) is defined in (3.5), \(\gamma_K\) certainly does (see below). Hence in this (somewhat weak) sense the "soft" and "hard" formulations are still separate even in the Kirchhoff model.

We need below the following specific result related to the case where \(\omega\) is a convex polygon.

**Lemma 3.6.** Let \(w_K\) be defined as above assuming that \(\omega\) is a convex polygon and that \(f \in H^{-1}(\omega)\). Further, let \(\rho \in H^1_0(\omega)\) and \(\psi \in H^1_0(\omega)\) be such that

(3.10a) \[ (\nabla \rho, \nabla \xi) = (\psi, \xi), \quad \xi \in H^1_0(\omega), \]

(3.10b) \[ (\nabla \psi, \nabla \xi) = \langle f, \xi \rangle, \quad \xi \in H^1_0(\omega). \]

Then \(\rho = w_K\) and \(\psi = -\Delta w_K\).
Proof. From (3.10a,b) it is obvious that \( \psi = -\Delta \rho \in H^1_0(\omega) \), so it suffices to show that \( \rho = w_K^\ast \). First, since \( \psi \in H^1(\omega) \) and since \( \omega \) is a convex polygon, it follows from (3.10a) that \( \rho \in H^2(\omega) \) and \( \rho \in \dot{H}^2(\omega) \), \( \bar{\omega} = \omega - \cup A_i \), \( A_i \) being the vertices of \( \omega \); i.e., \( \rho \in W \) (cf. [13]). Moreover, since \( \rho = \Delta \rho = 0 \) a.e. on \( \partial \omega \) and since \( \partial \omega \) consists of straight line segments only, it follows that \( \frac{\partial^2 \rho}{\partial t^2} = \frac{\partial^2 \rho}{\partial n^2} = 0 \) a.e. on \( \partial \omega \). Therefore and noting also that \( \frac{\partial z}{\partial t} = 0 \) a.e. on \( \partial \omega \) if \( z \in W \), it follows integrating by parts that

\[
(V\psi, Vz) = -(V(\Delta \rho), Vz) = -(V(\Delta \rho), Vz) - (1 - \nu) \sum_{i, j=1}^2 \left[ \frac{\partial^3 \rho}{\partial x_i \partial x_j \partial n^2} \frac{\partial z}{\partial x_i} \right]_1^2 \nu \Delta \rho + (1 - \nu) \frac{\partial^2 \rho}{\partial n^2} \frac{\partial z}{\partial n} \int_{\partial \omega}^2 \frac{\partial^2 \rho}{\partial n^2} \frac{\partial z}{\partial n} ds
\]

\[
= (c(V\rho), Tc(Vz)), z \in W.
\]

Hence by (3.10b), \( (c(V\rho), Tc(Vz)) = \langle f, z \rangle \), \( \forall z \in W \), so \( \rho \) minimizes \( S_K \) in \( W \) and accordingly, \( \rho = w_K^\ast \).

We can now prove the following result which will be needed in the next subsection.

Lemma 3.7. Let \( \omega \) be either a convex polygon or a smooth domain, and let \( (w, \theta, m, \gamma) = (w_K^\ast, \theta_K^\ast, m_K^\ast, \gamma_K^\ast) \in W \times \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \) be the solution to (3.8) for a given \( f \in H^{-1}(\omega) \), and with \( V \) defined by (3.5b). Then \( \gamma_K^\ast = -V(\Delta \omega_K^\ast) \in [L_2(\omega)]^2 \) and \( (w_K^\ast, \theta_K^\ast, m_K^\ast, \gamma_K^\ast) \) is a solution to equations (3.7) with \( h = 0 \) in (3.7b).

Moreover, if \( \omega \) is a convex polygon then \( \|\gamma_K^\ast\|_{0, \omega} = \|f\|_{-1, \omega} \), where

\[
\|f\|_{-1, \omega} = \sup_{z \in H^1_0(\omega)} \frac{\langle f, z \rangle}{|z|_{1, \omega}}.
\]

and if \( \omega \) is a smooth domain, then \( \|\gamma_K^\ast\|_{0, \omega} \leq C\|f\|_{-1, \omega} \), where \( C \) depends on \( \omega \).
Proof. If \( \tilde{\mathcal{U}}_K \in [L^2(\omega)]^2 \) and \( f \in H^{-1}(\omega) \), it follows from a simple closure argument that (3.8) remains valid if \( W \) is replaced by \( V \) and if on the left side \( <\cdot,\cdot> \) is replaced by \((\cdot,\cdot)\). To prove that \( \tilde{\mathcal{U}}_K = -\nabla(\Delta \omega_K) \), we integrate by parts in (3.9) to obtain

\[
<\tilde{\mathcal{U}}_K,\varphi> = -\int_{\omega} \nabla(\Delta \omega_K) \cdot \varphi dx_1 dx_2 \\
+ \int_{\partial \omega} \left[ \nu \Delta \omega_K + (1-\nu) \frac{\partial^2 \omega_K}{\partial n^2} \right] \varphi \cdot n \, ds \\
+ \int_{\partial \omega} (1-\nu) \frac{\partial^2 \omega_K}{\partial n \partial t} \varphi \cdot t \, ds, \quad \varphi \in V.
\]

Here the first boundary integral vanishes because \( \nu \Delta \omega + (1-\nu) \frac{\partial^2 \omega}{\partial n^2} = 0 \) on \( \partial \omega \) is the natural boundary condition associated to the problem of minimizing \( \mathcal{U}_K \), and the second boundary integral vanishes since \( \varphi \cdot t = 0, \varphi \in V \), assuming that \( V \) is defined by (3.5b). Hence \( \tilde{\mathcal{U}}_K = -\nabla(\Delta \omega_K) \). On the other hand from (3.10) we have \( \tilde{\mathcal{U}}_K \in [L^2(\omega)]^2 \) and because of the well-posedness of (3.8) we see that indeed \( \tilde{\mathcal{U}}_K = -\nabla(\Delta \omega_K) \).

Having verified that \( \tilde{\mathcal{U}}_K = -\nabla(\Delta \omega_K) \) we conclude from Lemma 3.6 that \( \tilde{\mathcal{U}}_K = \nabla \psi \) where \( \psi \in H^1_0(\omega) \) satisfies (3.10b), so \( \|\tilde{\mathcal{U}}_K\|_{0,\omega} = \|f\|_{-1,\omega} \) as asserted. Finally, if \( \omega \) is a smooth domain, a standard elliptic regularity estimate implies that \( \|\tilde{\mathcal{U}}_K\|_{0,\omega} \leq C\|\omega\|_{3,\omega} \leq C_1 \|f\|_{-1,\omega} \).

Remark 3.3. It is essential for our results in the next section that when \( \omega \) is a convex polygon, \( \|\tilde{\mathcal{U}}_K\|_{0,\omega} \) is bounded by \( \|f\|_{-1,\omega} \) independently of \( \omega \), in contrast to the smooth domain where the constant depends on \( \omega \).

3.4. Energy estimates in case of hard support.

Let us define the energy norms.
\[ \|u, \sigma\|^2 = A(u, u) + B(\sigma, \sigma), \quad (u, \sigma) \in U \times \mathcal{H} \]

and

\[ \|w, \theta, m, \gamma\|^2_{R} = A_{R}(w, \theta; w, \theta) + B_{R}(m, \gamma; m, \gamma), \quad (w, \theta, m, \gamma) \in H^1_0(\omega) \times V \times \mathcal{K} \times [L_2(\omega)]^2, \]

where the bilinear forms are as defined in subsections 3.1 and 3.2. Then by Lemma 3.2 we have the identity

\[ \|u_0 - u, \sigma_0 - \sigma\|^2 = \|u, \sigma\|^2 - 2Q(u) \]

whenever \( u \in U \) and \( \sigma \in \mathcal{H} \) satisfies the constraint (3.4b). Similarly by Lemma 3.4

\[ \|w_R - w, \theta_R - \theta, m_R - m, \gamma_R - \gamma\|^2_R = \|w, \theta, m, \gamma\|^2_R - 2\langle f, w \rangle, \]

where \( (w, \theta) \in H^1_0(\omega) \times V \) and \( (m, \gamma) \in \mathcal{K} \times [L_2(\omega)]^2 \) satisfies constraints (3.7c, d).

Let us first apply (3.12) to estimate the gap between the Reissner "quadruple" \((w_R, \theta_R, m_R, \gamma_R)\) and the Kirchhoff "quadruple" \((w_K, \theta_K, m_K, \gamma_K)\). By Lemma 3.7, the choice \((w, \theta, m, \gamma) = (w_K, \theta_K, m_K, \gamma_K)\) is legitimate in (3.12) under the assumptions that \( \omega \) is either a convex polygon or a smooth domain, \( f \in H^{-1}(\omega) \) and \( V \) is defined by (3.5b), i.e., the case of hard support. Upon simplifying the right side of (3.12) we obtain in this case the identity

\[ \|w_R - w_K, \theta_R - \theta_K, m_R - m_K, \gamma_R - \gamma_K\|^2_R = \frac{h^2}{\kappa} \|\gamma_K\|_{0, \omega}^2 \]

which together with Lemma 3.7 leads to the following

Theorem 3.1. Let \( \omega \) be either a) a convex polygon or b) a smooth domain, let \( f \in H^{-1}(\omega) \) and let \((w_R, \theta_R, m_R, \gamma_R)\) and \((w_K, \theta_K, m_K, \gamma_K)\) be the solution to (3.7) and (3.8), respectively, where \( V \) is defined by (3.5b). Then one has
in case a) the identity

\[ \|w_R - w_K, \theta_R - \theta_K, m_R - m_K, \gamma_R - \gamma_K\|_R^2 = (h^2/\kappa)\|f\|_{-1, \omega}^2 \]

where \( \|f\|_{-1, \omega} \) is defined as in Lemma 3.7, and in case b) the estimate

\[ \|w_R - w_K, \theta_R - \theta_K, m_R - m_K, \gamma_R - \gamma_K\|_R^2 = C(h^2/\kappa)\|f\|_{-1, \omega}^2 \]

where \( C \) depends on \( \omega \).

**Remark 3.4.** It is easy to verify that

\[ \|w_R - w_K, \theta_R - \theta_K, m_R - m_K, \gamma_R - \gamma_K\|_R^2 \leq E_K - E_R \]

where \( E_R \) and \( E_K \) stand for the total energy of the plate in the Kirchhoff model and Reissner-Mindlin model, respectively, i.e.,

\[ E_K = \mathcal{J}_K(w_K, \theta_K) = -\frac{1}{2} <f, w_K>, \]
\[ E_R = \mathcal{J}_R(w_R, \theta_R) = -\frac{1}{2} <f, w_R>. \]

In particular, if \( \omega \) is a convex polygon, Theorem 3.1 and Lemma 3.6 lead to the relative estimate

\[ (E_K - E_R)/E_K \leq C(\omega, f, \nu)h^2/\kappa_0, \]

where \( \kappa_0 \) is the shear correction factor, and

\[ C(\omega, f, \nu) = \frac{1}{6(1-\nu)} \int_\omega \Delta w_K f \, dx_1 \, dx_2 \int_\omega w_K f \, dx_1 \, dx_2 \]

For example, if \( \omega \) is the unit square and \( f(x) \equiv 1 \), then \( C(\omega, f, \nu) = 3.440428/(1-\nu) \).

**Remark 3.5.** In case of soft boundary conditions, constraint (3.7c) is more
restrictive and rules out the choice \((m, \pi) = (m^*_K, \pi^*_K)\) in (3.12). It is still possible to find \( (\tilde{m}_K, \tilde{\pi}_K) \in \mathcal{X}_x[L^2(\omega)]^2 \) which is close to \((\tilde{m}_K, \tilde{\pi}_K)\) away from the boundary and satisfies all the required constraints [16]. With such a construction, it is possible to show that if both \(f\) and \(\omega\) are sufficiently smooth then

\[
\| \omega_R - \omega_K, \theta - \theta_K, \quad \frac{\partial u}{\partial x} - \tilde{m}_K, \quad \frac{\partial \pi}{\partial x} - \tilde{\pi}_K \|_R^2 \leq C(\omega, f)h.
\]

For other estimates of this type see also [11], the references therein and [20].

We apply next (3.11) to bound the difference between the three-dimensional solution and the Kirchhoff solution. To this end, we need to construct a three-dimensional extension \((u_K, \sigma_K) \in \mathcal{U} \times \mathcal{H}\) of the Kirchhoff solution \((w_K, \theta_K, m_K, \pi_K)\). Following [16] we define \(u_K \in \mathcal{U}\) as

\[
(3.13) \quad u_K = (-x_3 \theta_K, 1, -x_3 \theta_K, 2, \quad w_K + \frac{1}{2} x_3 \psi),
\]

and \(\sigma_K \in \mathcal{H}\) as

\[
(3.14) \quad \sigma_K, 1j = -ax_3 m_K, 1j, \quad 1, j = 1, 2,
\]

\[
\sigma_K, 13 = a \left( \frac{1}{2} x_3^2 - \frac{1}{8} h^2 \right) \pi_K, 1, \quad 1, j = 1, 2
\]

\[
\sigma_K, 33 = a \left( \frac{1}{6} x_3^2 + \frac{1}{8} h^2 x_3 \right) f,
\]

where \(a = E / (1 - \nu^2)\) and \(\psi \in H^1_0(\omega)\) is so far unspecified. It is easy to check that \(\sigma_K\) satisfies (3.4b) so far as \(U\) is defined by (3.1b), so (3.11) applies with the choice \((u, \sigma) = (u_K, \sigma_K)\) in this case. After a short computation, the right side of (3.11) can then be expressed as

\[
\|u_K, \sigma_K\|^2 - 2Q(u_K) = \frac{(1 - \nu)^2}{1 - 2\nu} \int_\omega (\psi + \nu \Delta u_K)^2 dx_1 dx_2 + \frac{3(1 - \nu)^2}{160 h} \int_\omega |\nabla \psi|^2 dx_1 dx_2
\]
\[ + \frac{1}{5(1-\nu)^2} \int_\omega (|z_K|^2 + \nu \Delta w_K f) \, dx_1 \, dx_2 \]
\[ + \frac{17}{1680(1-\nu^2)} \int_\omega f^2 \, dx_1 \, dx_2. \]

Now if \( \omega \) is a convex polygon, the choice \( \psi = -\frac{\nu}{1-\nu} \Delta w_K \) is legitimate and leads, recalling also that \( \|z_K\|^2 = -\int_\omega \Delta w_K f \, dx_1 \, dx_2 = \|f\|^2_{-1, \omega} \) (see Lemma 3.6 and Lemma 3.7), to the identity
\[ \|u_K, \sigma_K\|^2 - 2Q(u_K) = \frac{32-8\nu+3\nu^2}{160(1-\nu)} \|f\|^2_{-1, \omega}. \]

On the other hand if \( \omega \) is a smooth domain, we can still find for any \( \delta > 0 \) a \( \psi \in H_0^1(\omega) \) so that
\[ (3.15a) \int_\omega (\psi + \frac{\nu}{1-\nu} \Delta w_K)^2 \, dx_1 \, dx_2 \leq C\delta^2 \|\Delta w_K\|^2_{1, \omega}, \]
and
\[ (3.15b) \int_\omega |\nabla \psi|^2 \, dx_1 \, dx_2 \leq C\delta^2 \|\Delta w_K\|^2_{1, \omega}. \]

Since \( \|\Delta w_K\|_{1, \omega} \leq C(\omega)\|f\|_{-1, \omega} \), we obtain in this case, choosing \( \delta = \sqrt{1-2\nu} h \), the estimate
\[ \|u_K, \sigma_K\|^2 - 2Q(u_K) \leq C(\omega) \frac{\nu^2}{\sqrt{1-2\nu}} \|f\|^2_{-1, \omega} + \frac{17h^4}{1680(1-\nu^2)} \|f\|^2_{0, \omega}. \]

We thus conclude the following:

**Theorem 3.2.** Assume that \( \omega \) is either a) a convex polygon or b) a smooth domain, let \( f \in L_2(\omega) \), let \((u_0, \sigma_0) \in U \times K\) be the solution to (3.4) with \( U \) defined by (3.1b), and let \((u_K, \sigma_K)\) be defined by (3.13-14) where
\((w_K, \theta_K, m_K, z_K) \in W \times V \times K \times V'\) is the solution to (3.8) with \( V \) defined by (3.5b) and either \( \psi = -\frac{\nu}{1-\nu} \Delta w_K \) (case a)) or \( \psi \) satisfies (3.15a, b) with \( \delta = \)
\( \sqrt{1-2\nu} h \) (case b)). Then one has in case a) the identity

\[
\| u_0 - u_K, \sigma_0 - \sigma_K \|^2 = C_1(\nu) h^2 \| f \|^2_{-1, \omega} + C_2(\nu) h^4 \| f \|^2_{0, \omega}
\]

and in case b) the estimate

\[
\| u_0 - u_K, \sigma_0 - \sigma_K \|^2 \leq C(\omega)(C_3(\nu) h^2 \| f \|^2_{-1, \omega} + C_2(\nu) h^4 \| f \|^2_{0, \omega})
\]

where \( \| f \|_{-1, \omega} \) is defined as in Lemma 3.7 and

\[
C_1(\nu) = \frac{32-8\nu+3\nu^2}{160(1-\nu)}, \quad C_2(\nu) = \frac{17}{1680(1-\nu^2)}, \quad C_3(\nu) = \frac{\nu^2}{\sqrt{1-2\nu}}.
\]

Remark 3.6. In case of soft boundary conditions it is possible to show that if \( \omega \) is smooth and \( f \) is sufficiently smooth, then

\[
\| u_0 - u_K, \sigma_0 - \sigma_K \|^2 \leq C(\omega, f)(1+C_3(\nu)) h
\]

where \( \sigma_K \) is close to \( \sigma_K \) away from the boundary strip \( a\omega \times (-h/2, h/2) \) [11], [16].

4. The plate paradox.

Let \( \omega_0 \subset \mathbb{R}^2 \) be the unit circular domain with the center at the origin, i.e.,

\[
\omega[0] = \{(x_1, x_2) : r^2 = x_1^2 + x_2^2 < 1\}.
\]

Let further \( \omega[n] \), \( n = 1, 2, \ldots \), be the sequence of regular \( (n+3) \)-polygons such that

\[
\omega[0] \supset \omega[n+1] \supset \omega[n+1] \supset \omega[n+1] \supset \omega[0]
\]

and

22
\[ \omega^{[n]} \to \omega^{[0]} \text{ as } n \to \infty \]

in the sense that for any \( x \in \omega^{[0]} \) there is \( n(x) > 0 \) such that \( x \in \omega^{[n]} \) for all \( n > n(x) \). Finally let \( \Omega^{[n]} = \omega^{[n]} \times (-h/2, h/2) \) and \( \Omega^{[0]} = \omega^{[0]} \times (-h/2, h/2) \).

Assume now that the unit load is imposed, i.e., \( f = p/D = 1 \) (see Section 2). Then for fixed thickness \( h \) there exists the unique solutions \( u^{[n]}_x, (w^{[n]}_R, \theta^{[n]}_R) \) and \( w^{[n]}_K \), \( n = 0, 1, 2, \ldots \), corresponding, respectively, to the three-dimensional, Reissner-Mindlin and Kirchhoff formulation of the plate bending problem with either hard or soft simple support. In Section 4.1 we will show that \( w^{[n]}_K \to w^{[0]}_K \neq w^{[0]}_K \) and give explicit expressions for \( w^{[0]}_K \) and \( w^{[0]}_K \). This is the plate paradox in the Kirchhoff model pointed out in \[7\], \[3\]. In Section 4.2 we will show that this paradox occurs also in the Reissner-Mindlin model and in the three-dimensional formulation in case of hard simple support. Finally in Section 4.3 we show that the paradox does not occur in the Reissner-Mindlin and three-dimensional formulations where the soft simple support is imposed. This was briefly noted in \[3\].

The results clearly show that seemingly minor changes in the boundary conditions can lead to a significant change of the solution on \( Q^{[n]} \), respectively \( \omega^{[n]} \), when \( n \) is large. In fact, we will see that there can be significant changes already when \( n = 1 \).

The main question we will address below in this section is whether as \( n \to \infty \)

\[ u^{[n]} \to u^{[0]} \text{ for the three-dimensional formulation} \]

\[ (w^{[n]}_R, \theta^{[n]}_R) \to (w^{[0]}_R, \theta^{[0]}_R) \text{ for the Reissner-Mindlin model} \]

and
4.1. The plate paradox for the Kirchhoff model.

We have shown in Lemma 3.6 that for \( n = 1, 2, \ldots \), \( \omega_k[n] = \rho[n] \) and

\[-\Delta \omega_k[n] = \psi[n] \]

where \( \rho[n] \) and \( \psi[n] \) satisfy (3.10a,b).

**Theorem 4.1.** Let \( \rho[^\omega], \psi[^\omega] \in H^1_0(\omega[0]) \) be such that

\[
\begin{align*}
(\nabla \rho[^\omega], \nabla \xi) &= (\psi[^\omega], \xi), \quad \xi \in H^1_0(\omega[0]) \quad (4.1a) \\
(\nabla \psi[^\omega], \nabla \xi) &= \langle f, \xi \rangle, \quad \xi \in H^1_0(\omega[0]) \quad (4.1b)
\end{align*}
\]

with \( f = 1 \). Then as \( n \to \infty \)

\[
\| \psi[n] - \psi[^\omega] \|_{H^1_0(\omega[0])} \to 0
\]

\[
\| \rho[n] - \rho[^\omega] \|_{H^1_0(\omega[0])} \to 0.
\]

Here we understand \( \psi[n] \) and \( \rho[n] \) extend by zero from \( \omega[n] \) to \( \omega[0] \).

**Proof.** Let \( P_n \) denote the orthogonal projection of \( H^1_0(\omega[0]) \) onto the

subspace \( H^1_0, n(\omega[0]) \), defined by

\[
H^1_0, n(\omega[0]) = \{ u \in H^1_0(\omega[0]) : u = 0 \text{ on } \omega[0] - \omega[n] \}
\]

and let \( \hat{\psi}[n] \) and \( \hat{\rho}[n] \) denote the extension of \( \psi[n] \) and \( \rho[n] \), respectively, by zero onto \( \omega[0] \). Then \( \hat{\psi}[n] = P_n \psi[^\omega] \) by (4.1b). From Theorem C.1 it then follows immediately that \( \hat{\psi}[n] \to \hat{\psi}[^\omega] \) in \( H^1_0(\omega[0]) \). From (4.1a) we then see that \( \rho[n] - P_n \rho[^\omega] \to 0 \) in \( H^1_0(\omega[0]) \) and therefore repeating the same argument that \( \rho[n] \to \rho[^\omega] \) in \( H^1_0(\omega[0]) \).

Let us now characterize \( \rho[0] = \omega_k[0] \) and \( \rho[^\omega] = \omega_k[^\omega] \) more explicitly.

To this end, note first that \( \rho[0] \) is the solution to the problem
where $D$ is given by (2.5). On the other hand, it is easy to see that $\rho^0$ is the solution of the problem

\begin{align}
(4.3a) \quad \Delta \rho^0 &= 1 \quad \text{on } \omega^0 \\
(4.3b) \quad \rho^0 &= 0 \quad \text{on } \partial \omega^0 \\
(4.3c) \quad \nu \Delta \rho^0 + (1-\nu) \frac{\partial^2 \rho^0}{\partial n^2} &= 0. 
\end{align}

Here, (4.3c) is the standard boundary condition for the simply supported circular plate [see e.g. [24], p. 554]. (4.2) and (4.3) show that

$$
\rho^0 = C_1 + C_2 r^2 + C_3 r^4,
$$

where $r^2 = x_1^2 + x_2^2$.

$$
C_3 = \frac{1}{64}
$$

and $C_1, C_2$ are determined from the boundary conditions. By simple computation we get

\begin{align}
(4.4a) \quad \rho^0(0,0) &= w^0_K(0,0) = \frac{1}{64} \frac{5+\nu}{1+\nu}, \\
(4.4b) \quad \rho^{[\omega]}(0,0) &= w^{[\omega]}_K(0,0) = \frac{3}{64},
\end{align}

and hence for $\nu = .3$ we have

$$
\frac{w^0_K(0,0)}{w^{[\omega]}_K(0,0)} = 1.36.
$$
i.e., the gap between \( w^K_0 \) and \( w^K_0 \) is 36% at the origin. Analogously for \( v = .3 \)

\[
\frac{\|w^K_0 - w^K_0\|}{\|w^K_0\|} = 0.287.
\]

**Remark 4.1.** We have assumed that \( w^n \) were regular polygons. As the proof shows, (4.5b) holds also when \( \{w^n\} \) is an arbitrary sequence of convex polygons such that \( w^n \to w^0 \) in the sense described above.

It is essential, however, that \( w^n \) are convex polygons. If we replace \( w^n \) by \( \tilde{w}^n \) where \( \tilde{w}^n \) are nonconvex polygons shown in Figure 4.1, then it was shown in [15] that \( \hat{\omega}^\infty \) satisfies

\[
\Delta \hat{\omega}^\infty = 1 \text{ in } \omega^0
\]

\[
\hat{\omega}^\infty = \frac{\delta \hat{\omega}^\infty}{\delta n} = 0 \text{ in } \partial \omega^0
\]

and hence

(4.c) \( \hat{\omega}^\infty(0,0) = \frac{1}{64} \)

---

**Figure 4.1.**

A nonconvex polygon \( w^n \).
4.2. The plate paradox for the three-dimensional and Reissner-Mindlin models.

We will analyze in detail the case of Reissner-Mindlin model only. The case of the three-dimensional formulation can be dealt with analogously.

**Theorem 4.2.** Let \( h \) be fixed and sufficiently small, and let \( w^h \) be the Reissner-Mindlin solution on \( \omega \) corresponding to unit load \( f = 1 \) on \( \omega \) and hard simple support on \( \delta \omega \), \( n = 0,1,2,... \). Then if \( w^h \) is extended by zero onto \( \omega^0 \), one has

\[
\|w^h - w^0\|_{\omega,1,\omega^0} \geq \alpha > 0
\]

for all \( n \geq n_0 \), \( n_0 \) large enough.

**Proof.** By Theorem 3.1 we have

\[
\|w^h - w^0\|_{\omega,1,\omega^0} \leq h^2 / \kappa \|f\|^2_{-1,\omega^0}.
\]

Note that \( \|f\|_{-1,\omega^0} \leq C_0 \) independently of \( n \). Using Lemma 3.3, and Theorem B.3 we see that

\[
\|w^h - w^0\|_{\omega,1,\omega^0} \leq C h^2 / \kappa \|f\|^2_{-1,\omega^0}.
\]

where \( C \) is independent of \( n \) and \( h \). On the other hand, we have by Theorem 4.1
\[ \|w_k^{[n]} - w_k^{[\omega]}\|_{1,\omega[0]} \to 0 \text{ as } n \to \infty \]

and

\[ \|w_k^{[\omega]} - w_k^{[0]}\|_{1,\omega[0]} > 0 \]

This shows that for sufficiently small \( h \) there is \( \alpha > 0 \) such that

\[ \|w_R^{[0]} - w_R^{[n]}\|_{1,\omega[0]} \geq \alpha > 0 \text{ for all } n > n_0. \]

Realizing that (in our case for \( f = 1 \))

\[ E_R = -\int_{\Omega[0]} w_R^{[n]} dx_1 dx_2, \quad E_R^{[0]} = -\int_{\Omega[0]} w_R^{[0]} dx_1 dx_2. \]

\[ E_K = -\int_{\Omega[0]} w_K^{[n]} dx_1 dx_2, \quad E_R = -\int_{\Omega[0]} w_K^{[0]} dx_1 dx_2. \]

we also have

\[ \int_{\omega[0]} (w_R^{[0]} - w_R^{[n]}) dx_1 dx_2 \geq \alpha > 0 \text{ as } n > n_0. \]

Using Theorem 3.2 and analogous arguments we get

**Theorem 4.3.** Let \( h \) be fixed and sufficiently small and let \( u_{03}^{[n]} = (u_{01}^{[n]}, u_{02}^{[n]}, u_{03}^{[n]}) \) be the three-dimensional solution of the plate bending problem on \( \Omega^{[n]} \) corresponding to the load \( p = D \) and hard simple support, \( n = 0, 1, 2, \ldots \). Then if \( u_{03}^{[n]} \) is extended by zero onto \( \Omega^{[0]} \), one has

\[ \|u_{03}^{[n]} - u_{03}^{[0]}\|_{1,\Omega^{[0]}} \geq \alpha > 0 \]

\[ \int_{\omega[0]} (u_{03}^{[n]}(x_1, x_2, h/2) + u_{03}^{[0]}(x_1, x_2, h/2)) dx_1 dx_2 \geq \alpha > 0 \]

for all \( n \geq n_0, \quad n_0 \) sufficiently large. \( \square \)

Theorems 4.2 and 4.3 show that the hard simple support leads not only to
the paradox in the Kirchhoff model but also in the three-dimensional formulation and the Reissner-Mindlin model. (In Section 4.3 we will show that the paradox occurs neither in the three-dimensional formulation nor Reissner-Mindlin model when the simple soft support is imposed.)

The proof employed the fact that the Kirchhoff model approximates very well the Reissner-Mindlin and three-dimensional formulations for the hard support. This shows that the circular plate and polygonal plate solutions are far apart in the entire region and not only in the area close to the boundary, where boundary layer effects occur.

The above results show that plausibly unimportant changes in the boundary conditions could lead to significant changes in the solution through the entire region even if the three-dimensional linear elasticity model is used. We expect that the paradox will occur also in nonlinear formulations. For engineering implications of effects of this type we refer to [6].

4.3. The "nonparadox" in case of soft simple support.

We will prove in this section that in contrast to the hard simple support the solution on \( w^{[n]} \) converges to the solution on \( w^{[0]} \) for both the Reissner-Mindlin and the three-dimensional plate model. This is in obvious contrast to the hard simple support. We will elaborate in detail on the case of the Reissner-Mindlin model. The analysis of the three-dimensional model is analogous.

Let us denote

\[
D_n = w^{[n+1]} - w^{[n]}, \quad n = 1, 2, \ldots
\]

\[
D_0 = w^{[1]}
\]

\[
D_0^n = w^{[0]} - w^{[n]}, \quad n = 1, 2, \ldots,
\]

see Figure 4.2.
Let $L = (L_2(\omega^{[0]}))^3$, $u = (w, \theta) \in L$ and

$\mathcal{Y}_0 = \{ u \in L : w \in H^1_0(\omega^{[0]}), \theta \in (H^1(\omega^{[0]}))^2 \}$

$\mathcal{Y}_n = \{ u \in L : w \in H^1_0(\omega^{[0]}), w = 0 \text{ on } \mathcal{D}_n^0, \theta \in (H^1(\omega^{[0]}))^2 \}$

$\mathcal{I}_n = \{ u \in L : w \in H^1_0(\omega^{[0]}), \theta \in (H^1(\omega^{[n]}))^2, \varphi \in (H^1(\mathcal{D}_m))^2, m = n, n+1, \ldots \}$

$\mathcal{I}_{n,m} = \{ u \in L : w \in H^1_0(\omega^{[0]}), w = 0 \text{ on } \mathcal{D}_n^0, \theta \in (H^1(\omega^{[m]}))^2, \varphi \in (H^1(\mathcal{D}_j))^2, j = m, m+1, \ldots \}$.

We have $\mathcal{I}_n \subset \mathcal{I}_0$, $\mathcal{I}_0 \subset \mathcal{I}_n$ and 

$\mathcal{I}_{n,m} \supset \mathcal{I}_n$, $\mathcal{I}_{n,m} \subset \mathcal{I}_m$.

All the spaces are embedded in $\mathcal{I}_1$. Further, let
\[ \mathcal{Z}_n = \{ u \in L : \omega \in H^1(\omega^{[n]}), \Theta \in (H^1(\omega^{[n]}))^2 \} \]

\[ \mathcal{Z}_n = \{ u \in \mathcal{Z}_n : \omega \in H^1_0(\omega^{[n]}) \} \]

and

\[ \mathcal{A}_R^1(w, \Theta; z, \varphi) = \sum_{i=0}^{\infty} \mathcal{A}_R^{i+1}(u, v) \]

where \( \mathcal{A}_R^i \) is given in Section 3.2 for the region \( \omega \) and \( \mathcal{D}_1 \) has the same form but is integrated only over \( \mathcal{D}_1 \). Analogously we define \( \mathcal{A}_R^{[n]} \), etc.

We finally supply \( \mathcal{J}_1 \) with the norm

\[ \|u\|^2 = \sum_{i=0}^{\infty} \mathcal{A}_R^{i+1}(u, u). \]

To see that \( \| \cdot \| \) is indeed a norm, assume that \( u = (w, \Theta) \in \mathcal{J}_1 \) and \( \|u\| = 0 \). Then since the first term in the expression for \( \mathcal{D}_1 \) is the same as in the case of plane elasticity (where \( \Theta_1, \Theta_2 \) play the role of the displacements) we have on \( \mathcal{D}_j \), \( \Theta_1 = a_j + c_j x_2, \Theta_2 = b_j - c_j x_1 \) and because \( \|\Theta - \varphi\|_0, \mathcal{D}_j = 0 \) we get \( c_j = 0 \). Hence \( w = d_j + a_j x_1 + b_j x_2 \) on \( \mathcal{D}_j \) and so because \( w \in H^1_0(\omega^{[0]}) \) we get \( w = 0 \) and \( a_j = b_j = 0, \ j = 0, 1, 2, \ldots \) (see also Appendix B). Hence \( u = 0 \) and accordingly, \( \| \cdot \| \) is a norm on \( \mathcal{J}_1 \).

For \( u \in \mathcal{Z}_n \) let \( \|u\|^2_{\mathcal{R}, \omega^{[n]}} = \mathcal{A}_R^{[n]}(u, u) \). Then by Theorem B.1

\[ \inf_{\text{abc}} \|\Theta_1 - (a + cx_2), \Theta_2 - (b - cx_2)\|_{1, \omega^{[n]}} \leq C_n \|u\|_{\mathcal{R}, \omega^{[n]}} \]

\[ \inf_{\text{abcd}} \|w - (d + ax_1 + bx_2 + cx_1 x_2)\|_{1, \omega^{[n]}} \leq C_n \|u\|_{\mathcal{R}, \omega^{[n]}}. \]

Here \( C_n \) depends in general on \( \omega^{[n]} \).

Assume now that for an \( n_0 > 0 \)
(4.6a) \( f \) has compact support in \( \omega \).

(4.6b) \[
\int_{\omega} f dx_1 dx_2 = \int_{\omega} f x_1 dx_1 dx_2 = \int_{\omega} f x_2 dx_1 dx_2 = \int_{\omega} f x_1 x_2 dx_1 dx_2 = 0
\]

and that \( n > n_0, m > n_0 \). Then for \( u \in \mathcal{F}_n, n \geq n_0 \),

\[
\int_{\omega[0]} f w dx_1 dx_2 = \int_{\omega[0]} f w dx_1 dx_2 \leq C_{n_0} \| u \|
\]

and hence for \( n, m \geq n_0 \) there exist unique \( u(\mathcal{F}_n) \in \mathcal{F}_n, u(\mathcal{F}_n) \in \mathcal{F}_n \), \( u(\mathcal{L}_n, m) \in \mathcal{L}_n, m \), \( u(\mathcal{Z}_n) \in \mathcal{Z}_n \) such that

\[
t_R^0(u(\mathcal{F}_n), \mathcal{F}_n) = \int_{\omega[0]} f z dx_1 dx_2, \quad \forall \mathcal{F}_n \in (z, \varphi) \in \mathcal{F}_n
\]

and analogously for \( u(\mathcal{F}_n), u(\mathcal{L}_n, m), u(\mathcal{Z}_n) \). Obviously \( u(\mathcal{F}_n) = u[n] \) and \( u(\mathcal{Z}_n) = u[n] \) and \( u(\mathcal{L}_n, m) = u(\mathcal{Z}_n) \) on \( \omega[n] \) and is zero on \( \mathcal{D}_n^0 \).

Using Theorem C.1 we get

(4.7a) \( u[n]^0 = u(\mathcal{F}_n) = u(\mathcal{F}_n) + \rho(\mathcal{F}_n, \mathcal{F}_n) \)

(4.7b) \( \| u(\mathcal{F}_n) \|^2 = \| u(\mathcal{F}_n) \|^2 + \| \rho(\mathcal{F}_n, \mathcal{F}_n) \|^2 \)

(4.7c) \( \| \rho(\mathcal{F}_n, \mathcal{F}_n) \| \rightarrow 0 \) as \( n \rightarrow \infty \)

(4.8a) \( u(\mathcal{F}_n) = u(\mathcal{F}_n) + \rho(\mathcal{F}_n, \mathcal{F}_n) \)

(4.8b) \( \| u(\mathcal{F}_n) \|^2 = \| u(\mathcal{F}_n) \|^2 + \| \rho(\mathcal{F}_n, \mathcal{F}_n) \|^2 \)

(4.8c) \( \| \rho(\mathcal{F}_n, \mathcal{F}_n) \| \rightarrow 0 \) as \( n \rightarrow \infty \)
\[(4.9a)\quad u(\mathcal{L}_{n,m}) = u(\mathcal{J}_n) + \rho(\mathcal{L}_{n,m}, \mathcal{J}_n)\]

\[(4.9b)\quad \|u(\mathcal{L}_{n,m})\|^2 = \|u(\mathcal{J}_n)\|^2 + \|\rho(\mathcal{L}_{n,m}, \mathcal{J}_n)\|^2\]

\[(4.9c)\quad \|\rho(\mathcal{L}_{n,m}, \mathcal{J}_n)\| \rightarrow 0 \quad \text{as} \quad m \rightarrow \infty.\]

\[(4.10a)\quad u(\mathcal{L}_m) = u(\mathcal{L}_{n,m}) + \rho(\mathcal{L}_m, \mathcal{L}_{n,m})\]

\[(4.10b)\quad \|u(\mathcal{L}_m)\|^2 = \|u(\mathcal{L}_{n,m})\|^2 + \|\rho(\mathcal{L}_m, \mathcal{L}_{n,m})\|^2\]

\[(4.10c)\quad \|\rho(\mathcal{L}_m, \mathcal{J}_n, m)\| \rightarrow 0 \quad \text{as} \quad n \rightarrow \infty.\]

Let now \( \varepsilon > 0 \) and \( n > \max(n(\varepsilon), n_0) \). Then we have

\[\|\rho(\mathcal{J}_0, \mathcal{J}_n)\|^2 < \varepsilon\]

\[\|\rho(\mathcal{J}_n, \mathcal{J}_0)\|^2 < \varepsilon.\]

Using (4.7) - (4.10) we get

\[\|u(\mathcal{J}_0)\|^2 + \|\rho(\mathcal{L}_m, \mathcal{J}_0)\|^2 = \|u(\mathcal{J}_m)\|^2 = \|u(\mathcal{L}_{n,m})\|^2 + \|\rho(\mathcal{L}_m, \mathcal{L}_{n,m})\|^2\]

\[= \|u(\mathcal{J}_n)\|^2 + \|\rho(\mathcal{L}_{n,m}, \mathcal{J}_n)\|^2 + \|\rho(\mathcal{J}_m, \mathcal{L}_n)\|^2\]

\[= \|u(\mathcal{J}_n)\|^2 - \|\rho(\mathcal{J}_0, \mathcal{J}_n)\|^2 + \|\rho(\mathcal{J}_n, \mathcal{J}_0)\|^2\]

\[+ \|\rho(\mathcal{L}_m, \mathcal{J}_n, m)\|^2\]

and hence for \( n, m \geq \max(n(\varepsilon), n_0) \)

\[\|\rho(\mathcal{L}_m, \mathcal{J}_0)\|^2 + \|\rho(\mathcal{J}_0, \mathcal{J}_n)\|^2 = \|\rho(\mathcal{L}_{n,m}, \mathcal{J}_n)\|^2 + \|\rho(\mathcal{J}_m, \mathcal{L}_n, m)\|^2 \leq 2\varepsilon\]

which yields

\[\|\rho(\mathcal{L}_{n,m}, \mathcal{J}_n)\|^2 \leq 2\varepsilon.\]

Therefore
\[ u(\mathcal{G}_0) - u(\mathcal{L}_{n,n}) = u(\mathcal{G}_0) - u(\mathcal{G}_n) + u(\mathcal{G}_n) - u(\mathcal{L}_{n,n}) = \rho(\mathcal{G}_0, \mathcal{G}_n) - \rho(\mathcal{L}_{n,n}, \mathcal{G}_n) \]

and hence

\[ \|u(\mathcal{G}_0) - u(\mathcal{L}_{n,n})\| \leq c^{1/2} + \sqrt{2c} \leq Cc^{1/2}. \]

Because as we said above \( u(\mathcal{L}_{n,n}) = u[n] \) on \( \omega[n] \) and \( = 0 \) on \( D_n \), \( u[n] \rightarrow u[0] \) in the space \( \mathcal{G}_1 \) or in any \( \mathcal{G}_m \) for \( m \) fixed.

**Remark 4.2.** Note that until now we did not use Theorem B.3, we used only Theorem B.1. 

So far we have assumed that \( f \) satisfies the conditions 4.6. Let us now study the general case. Assume that \( f \in L_2(\omega[0]) \).

Let us first note that if \( u = (w, \theta) \in \mathcal{L}_{n,n} \), then \( w \in H_0^1(\omega[0]) \) and

\[ (4.11) \quad \|w\|_{1,\omega[n]} = \|w\|_{1,\omega[0]} \leq C\|u\| \]

with \( C \) independent of \( n \) because of Theorem B.3.

For \( 0 < \Delta < 1/2 \) we denote

\[ R_\Delta = \{(x_1, x_2) : x_1^2 + x_2^2 > 1 - \Delta\} \]

\[ \partial R_\Delta = \{(x_1, x_2) : x_1^2 + x_2^2 = 1 - \Delta\}. \]

Then

\[ \|w\|_{0,R_\Delta} \leq C\Delta\|w\|_{1,\omega[0]} \leq C\Delta\|u\|. \]

\[ \|w\|_{0,\partial R_\Delta} \leq C\Delta^{1/2}\|w\|_{1,\omega[0]} \leq C\Delta^{1/2}\|u\|. \]

Let now

\[ f_\Delta = \begin{cases} f & \text{on } R_\Delta \\ 0 & \text{on } \omega[0] - R_\Delta \end{cases} \]

and
\[ g_\Delta = (a+bx_1+cx_2+dx_1x_2)\mathcal{O}_\Delta, \]

where \( \mathcal{O}_\Delta \) is the Dirac function concentrated on \( \partial R_\Delta \) and \( a, b, c, d \) are such that \( f_\Delta + g_\Delta \) satisfies (4.6).

For \( n > n_1, \Delta \) such that \( F_\Delta < \omega ^{n_1, \Delta} \), let \( u_\Delta(\mathcal{X}, n) \) and \( u_\Delta(\mathcal{Y}) \) be the solutions when instead of \( f \) the function \( f_\Delta \) is used. Then we get

\[
\|u_\Delta(\mathcal{X}, n) - u(\mathcal{X}, n)\| \leq C\Delta^{1/2},
\]

\[
\|u_\Delta(\mathcal{Y}) - u(\mathcal{Y})\| \leq C\Delta^{1/2},
\]

where \( C \) is independent of \( n \) and \( \Delta \) but in general depends on \( f \). Hence we can select \( \Delta \) so that \( C\Delta^{1/2} < c \). Further we have shown

\[
\|u_\Delta(\mathcal{X}, n) - u_\Delta(\mathcal{Y})\| < c
\]

for all \( n \geq n_1(c) \) and therefore

\[
\|u(\mathcal{X}, n) - u(\mathcal{Y})\| < Cc
\]

for all \( n \geq n_1(c) \). Since \( u(\mathcal{Y}) = u_\mathcal{R}^{[0]} \) and \( u(\mathcal{X}, n) = u_\mathcal{R}^{[n]} \), we get

\[
\|u_\mathcal{R}^{[0]} - u_\mathcal{R}^{[n]}\| \to 0 \text{ as } n \to \infty.
\]

Here \( u_\mathcal{R}^{[n]} = (w_\mathcal{R}^{[n]}, \theta_\mathcal{R}^{[n]}) \) is understood to be extended by zero on \( \mathcal{D}_n^{0} \) and \( \| \cdot \| \) is the norm in \( \mathcal{F}_1 \) (note that \( w_\mathcal{R}^{[n]} \in H^1_0(\omega_1) \), but \( \theta_\mathcal{R}^{[n]} \notin H^1(\omega_0) \), although \( \theta_\mathcal{R}^{[n]} \in H^1(\omega_0) \)). Because the functions in \( H^1(\omega_0) \) with compact support are dense in \( H^0_0(\omega_0) \), there is \( \tilde{w}^{[n]} \in H^1_0(\omega_0) \) such that

\[
\|w^{[0]} - \tilde{w}^{[n]}\| \leq c \text{ for all } n \geq n_2(c).
\]

Hence with \( \tilde{u}^{[n]} = (\tilde{w}^{[n]}, \theta_\mathcal{R}^{[n]}) \) we get

\[
\|\tilde{u}^{[n]} - u_\mathcal{R}^{[0]}\| \to 0 \text{ as } n \to \infty.
\]

Hence using Theorem B.2.
\[ \|w_R^{[n]} - w_R^{[0]}\|_{H^1(\omega[n])}^2 + \|\theta_R^{[n]} - \theta_R^{[0]}\|_{H^1(\omega[n])}^2 \to 0 \quad \text{as} \quad n \to \infty. \]

Summarizing, we have proven

**Theorem 4.4.** Let \( f \in L^2(\omega^{[0]}) \) and let \( u_R^{[n]} = (w_R^{[n]}, \theta_R^{[n]}) \), respectively \( u_R^{[0]} = (w_R^{[0]}, \theta_R^{[0]}) \), be the Reissner-Mindlin solution on \( \omega^{[n]} \), respectively \( \omega^{[0]} \), for the soft simple support and fixed \( h \). Then

\[ \|w_R^{[n]} - w_R^{[0]}\|_{H^1(\omega[n])} + \|\theta_R^{[n]} - \theta_R^{[0]}\|_{H^1(\omega[n])} \to 0 \quad \text{as} \quad n \to \infty. \]

We see that in contrast to the hard support there is no plate paradox when the soft support is imposed. Hence the soft simple support is physically more natural than the hard simple support.

**Remark 4.3.** In Theorem 4.2 we assumed that \( f \in L^2(\omega^{[0]}) \) while the solutions \( u_R^{[0]} \) and \( u_R^{[n]} \) were defined for any \( \tilde{t} \in H^{-1}(\omega^{[0]}) \), respectively \( f \in H^{-1}(\omega^{[n]}) \). If \( f \) has compact support then Theorem 4.4 holds also for \( f \in H^{-1}(\omega^{[0]}) \). We can weaken the assumptions on \( f \) in Theorem 4.4, e.g., so that \( f \in H^{\alpha}(\omega^{[0]}) \), \( \alpha > -1/2 \), but the proof will not hold for \( f \in H^{-1}(\omega^{[0]}) \).

**Remark 4.4.** We have assumed that \( \omega^{[n]} \) is the sequence of regular polygons. This assumption was used only when using Theorem B.3. Hence Theorem 4.4 holds for any regular family of domains (see Appendix B). If \( f \) satisfies (4.6) then there is no need for the regularity (see Remark 4.2) of the family of domains under consideration and Theorem 4.4 holds in the full generality.

**Remark 4.5.** We have assumed in Theorem 4.5 that \( h > 0 \) is fixed (i.e., independent of \( n \)). We could also consider a two-parameter family of problems where both \( n \) and \( h \) vary. Then, for \( n \) fixed and \( h \to 0 \), \( u_R^{[n]} \to u_K^{[n]} \) (and hence for \( h \to 0 \) the difference between soft and hard support disap-
pears). Hence combining the results of this section with Section 4.2, we see that

$$\lim_{n \to \infty} \lim_{h \to 0} u^{(n)}_R = \lim_{h \to 0} \lim_{n \to \infty} u^{(n)}_R.$$

In the quite analogous way as we have proved Theorem 4.4 we can prove Theorem 4.5. Let $h$ be fixed and $u^{[0]}$, respectively $u^{[n]}$, be the solution of the three-dimensional plate problem on $\Omega^{[0]}$, respectively $\Omega^{[n]}$, with simple soft support. Assume that the load $p \in L^2(\omega^{[0]})$. Then

$$\|u^{[0]} - u^{[n]}\|_{1,\Omega^{[n]}} \to 0$$
as $n \to \infty$.

Remark 4.6. Remarks 4.3-4.5 are valid also for the three-dimensional plate model.

4.5. Some additional considerations.

As we have seen the Kirchhoff model (biharmonic equation) leads to paradoxical behavior for the hard simple support. The same mathematical formulation describes also other problems and hence leads to the same paradoxical behavior.

As an example, we mention the problem of reinforced tube shown in Figure 4.3a,b. The reinforcement is attached by an unextendable tape to the exterior surface. Here we have the paradox consisting of the fact that the stress caused by hydrostatic pressure is different for the polygonal and circular outer surfaces.

37
Figure 4.3.

Reinforced polygonal and circular tubes.

Analogous examples can very likely be found in other fields than elasticity where the problem reduces to the biharmonic (or polyharmonic) equation.

We have shown the paradoxical behavior for \( n \to \infty \) and \( h \) relatively large compared with \( 1/n \) (see Remark 4.5). Hence the question arises how large will be the difference between the hard and soft support in three-dimensional formulation for \( n \) fixed and \( h \to 0 \). To this end we consider a square plate with side length \( = 1 \). In Table 4.1 we give the values of

\[
\frac{\left| E_{\text{SOFT}} - E_{\text{HARD}} \right|^{1/2}}{E_{\text{SOFT}}} = \eta(h)
\]

and

\[
\frac{\left| E_{\text{HARD}} - E_{K} \right|^{1/2}}{E_{\text{HARD}}} = \xi(h).
\]

Here by \( E_{\text{SOFT}} \) and \( E_{\text{HARD}} \) we denoted the (3-dim) plate energy for the soft and hard support and by \( E_{K} \) the plate energy of the Kirchhoff model for Poisson ratio \( \nu = 0 \) (see also [7]).

Appendix A. Well-posedness of variational problems (3.4), (3.7), and (3.8).

We make use of the following basic theorem, see [18].

**Theorem A.1.** Let $H$ be a Hilbert space and $B$ be a bilinear form on $H \times H$ which satisfies

\begin{align*}
(A.0) & \quad B(u, v) = B(v, u), \quad u, v \in H, \\
(A.1) & \quad |B(u, v)| \leq C\|u\|_H \|v\|_H, \quad u, v \in H, \\
(A.2) & \quad \sup_{\|v\|_H = 1} B(u, v) \geq c\|u\|_H \quad \forall u \in H,
\end{align*}

where $C$ and $c$ are positive constants. Then if $F$ is any bounded linear functional on $H$, there is a unique $u \in H$ satisfying

\begin{equation}
B(u, v) = F(v), \quad v \in H.
\end{equation}

In applying Theorem A.1 to problems (3.4), (3.7), and (3.8), we choose the following notation:

a) Three-dimensional model (Eqs. (3.4)).

\[
H = U \times H,
\]

\[
B(u, \sigma; v, \tau) = (\sigma \Sigma^{-1} \tau)_H - (\varepsilon(u), \tau)_H - (\sigma, \varepsilon(v))_H,
\]

\[
F(v, \tau) = -Q(v).
\]

b) Reissner-Mindlin model (Eqs. (3.7)).

\[
H = H^1_0(\omega) \times V \times X \times [V_2(\omega)],
\]

\[
B(w, \theta, m, z; p, k, \zeta) = (m \Sigma^{-1} k)_H - (\varepsilon(\theta), k)_H
\]

\[
- (\varepsilon(p), m)_H - (\theta - \nabla w, \zeta) - (p - \nabla z, \gamma) + \frac{h^2}{\kappa}(\nu, \zeta),
\]
\[ F(z, \varphi, k, \zeta) = -\langle f, z \rangle. \]

c) Kirchhoff model (Eqs. (3.8)).

\[ H = WxVxXxV', \]

\[ B(w, \theta, m, z; \varphi, k, \zeta) = (m, T^{-1}k)_{X} - \langle \varepsilon(\theta), k \rangle_{X} - \varepsilon(\varphi, m)_{X} - \langle \varphi - \nabla w, \zeta \rangle - \langle \varphi - \nabla z, \gamma \rangle, \]

\[ F(z, \varphi, k, \zeta) = -\langle f, z \rangle. \]

Then in each case, \( B \) is symmetric, \( F \) is a bounded linear functional on \( H \), and the variational problem takes the general form (A.3). Thus it suffices to show that (A.1) and (A.2) hold.

**Theorem A.2.** Assume that \( \omega \) is a bounded Lipschitz domain and that the parameters \( \nu, h, \) and \( k \) satisfy

\[ 0 \leq \nu < 1/2, \quad \tilde{h} \leq h \leq \tilde{h}^{-1}, \quad \tilde{k} \leq k \leq \tilde{k}^{-1}, \]

where \( \tilde{h} > 0 \) and \( \tilde{k} > 0 \) are given. Then in each of the above three cases there are the constants \( C = C(\tilde{h}, \tilde{k}) \) and \( c = c(\omega, \tilde{h}, \tilde{k}) \) such that (A.1) and (A.2) hold.

**Proof.** In view of (3.2) and (3.6) the mappings \( S^{-1} : H \rightarrow H \) and \( T^{-1} : X \rightarrow X \) are uniformly bounded in the assumed range of \( \nu \). It then follows easily that the assertion concerning (A.1) holds, so let us concentrate on showing that (A.2) is true.

a) The three-dimensional model.

Let \((u, \sigma) \in U \times \mathcal{H}\) be given and let

\[ (\sigma_{ij})_{1,1} = \frac{1}{3} \text{tr}(\sigma) \delta_{ij}, \quad 1, j = 1, 2, 3. \]

Then \( \| \sigma \|^2_{\mathcal{H}} = \| \sigma - \sigma_{0} \|^2_{\mathcal{H}} + \frac{1}{3} \| \text{tr}(\sigma) \|^2_{0, \Omega} \) and it follows from (3.2) that
\[(\varphi, \mathbf{S}^{-1} \varphi) = \frac{D}{E}((1 + \nu)\|\sigma - \sigma_0\|_H^2 + (1 - 2\nu)\|\sigma_0\|_H^2) \geq \frac{h^3}{12}\|\sigma - \sigma_0\|_H^2, \quad (0 \leq \nu \leq 1/2).\]

We make use the following lemma which is related to the well-posedness of the Stokes problem. For the proof, cf. [12].

**Lemma A.1.** There exists \(v_0 \in U\) and a constant \(C_1\) depending on \(\omega\) and \(\tilde{h}\) such that the following inequalities hold:

\[\|v_0\|_1, \Omega \leq C_1\|\text{tr}(\varphi)\|_{0, \Omega}\]
\[(\text{div} \ v_0, \text{tr}(\varphi)) \geq \|\text{tr}(\varphi)\|_{0, \Omega}^2.\]

With \(v_0\) as in Lemma A.1 we now set \((v, \tau) = (-u-\delta v_0, \varphi - \delta^2 \overline{e}(u))\) where \(\delta\) is a constant to be specified shortly. Then applying (A.4), the inequality \((\tau_1, \tau_2) \leq (s/2)\|\tau_1\|_H^2 + (1/2s)\|\tau_2\|_H^2, \quad (s > 0),\) and Lemma 3.1, we have that

\[B(y, \varphi; v, \tau) = (\varphi, \mathbf{S}^{-1} \varphi) + \frac{1}{3}\delta(\text{tr}(\varphi), \text{div} \ v_0)\]
\[+ \delta(\sigma - \sigma_0, \sigma_0) + \frac{1}{2}\delta^2\|\overline{e}(u)\|_H^2 - \delta^2(\sigma, \mathbf{S}^{-1} \overline{e}(u))_H\]
\[\geq \left[\frac{1}{12}h^3 - C_2\delta - C_3\delta^2\right]\|\sigma - \sigma_0\|_H^2 + \left[\frac{1}{6}\delta - C_4\delta^2\right]\|\text{tr}(\varphi)\|_{0, \Omega}^2 + c_1\delta^2\|\overline{e}(u)\|_{1, \Omega}^2\]
\[\geq \min\left\{\frac{1}{12}h^3 - C_2\delta - C_3\delta^2, \frac{1}{2}\delta - C_4\delta^2, c_1\delta^2\right\}(\|\overline{u}\|_{1, \Omega}^2 + \|\sigma\|_H^2).\]

Thus, choosing \(\delta\) to be a sufficiently small positive number, we have found \((v, \tau) \in U \times H\) such that \(\|v, \tau\|_H \leq C\|u, \sigma\|_H\) and \(B(y, \sigma; v, \tau) \geq c\|y, \sigma\|_H^2\) where \(C\) and \(c\) depend only on \(\omega\) and \(\tilde{h}\). Hence, (A.2) is true in case a) with \(c\) depending on \(\omega\) and \(\tilde{h}\).

b) The Reissner-Mindlin model.

Given \((w, \theta, \mathbf{m}, \gamma) \in H^1_0(\omega) \times V \times H \times L^2(\omega)\), let \((z, \varphi, k, \zeta) =\)
\((-w, -\theta, \frac{m - \delta e(\theta)}{m}, \frac{\varphi - \delta(\varphi - \varphi_0)}{\varphi - \varphi_0})\) where \(\delta\) is a constant to be specified. Then noting that by (3.6), \(\frac{m - \delta e(\theta)}{m} \geq \|m\|_A^2/(1+\nu)\), and recalling Lemma 3.3, we have

\[
\mathcal{B}(w, \theta, m, \varphi; z, \varphi, k, \zeta) = (m, T^{-1}m, \varphi) + (h^2/\kappa)\|\varphi\|^2_{0, \omega}
\]

\[
+ \delta \|e(\theta)\|^2_{\mathcal{X}} - \delta(m, T^{-1}e(\theta))\|e(\theta)\|^2_{\mathcal{X}} + \delta \|\varphi - \varphi_0\|^2_{0, \omega}
\]

\[
- \delta(h^2/\kappa)(\varphi - \varphi_0)
\]

\[
\geq \left(\frac{1}{1+\nu} - C_1 \delta\right)\|m\|^2_{\mathcal{X}} + \frac{1}{2}\|e(\theta)\|^2_{\mathcal{X}} + \frac{1}{2}\|\varphi - \varphi_0\|^2_{0, \omega}
\]

\[
+ (h^2/\kappa)(1 - C_2 \delta^2 h^2/\kappa)\|\varphi\|^2_{0, \omega}
\]

\[
\geq \min\left(\frac{1}{1+\nu} - C_1 \delta, c_1 \delta, h^2/\kappa(1 - C_2 \delta^2 h^2/\kappa)\right) \times \|w, \theta, m, \varphi\|^2_{H'}
\]

Thus if \(\delta\) is small enough we have found \((z, \varphi, k, \zeta) \in H\) such that

\[
\|z, \varphi, k, \zeta\|_H \leq C \|w, \theta, m, \varphi\|_H \quad \text{and} \quad \mathcal{B}(w, \theta, m, \varphi; z, \varphi, k, \zeta) \geq c \|w, \theta, m, \varphi\|^2_H
\]

where the constants depend only on \(\omega, \bar{h}\) and \(\bar{k}\). These prove the assertion in case b).

c) The Kirchhoff model.

Given \((w, \theta, m, \varphi) \in H\), let \((z, \varphi, k, \zeta) = (-w, -\theta - \delta \varphi_0, (m - \delta \varphi_0), (\varphi - \delta \varphi_0))\), where \(\varphi_0 \in V\) and \(\zeta_0 \in V'\) are defined so as to satisfy

\[
\|\varphi_0\|_{1, \omega} = \|\varphi\|_{V'}; \quad \langle \varphi, \varphi_0 \rangle = \|\varphi\|^2_{V'};
\]

\[
\|\zeta_0\|_{V'} = \|\theta - \varphi_0\|_{1, \omega}; \quad \langle \theta - \varphi_0, \zeta_0 \rangle = \|\theta - \varphi_0\|^2_{1, \omega'}
\]

which obviously is possible. As in case b), one then finds that for a sufficiently small \(\delta\), \(\|z, \varphi, k, \zeta\|_H \leq C \|w, \theta, m, \varphi\|_H \quad \text{and} \quad \mathcal{B}(w, \theta, m, \varphi; z, \varphi, k, \zeta) \geq c \|w, \theta, m, \varphi\|^2_H\) where \(C\) and \(c\) depend only on \(\omega\), and so the assertion follows in case c).
Appendix B. The Korn inequality.

Let \( \omega \) be a bounded Lipschitz domain and define the seminorm

\[
\|\theta\|_{E(\omega)} = \left\{ \int_{\omega} \sum_{j=1}^{2} |\epsilon_{1j}(\theta)|^2 \, dx \, dx \right\}^{1/2}, \quad \theta \in (H^1(\omega))^2,
\]

where \( \epsilon_{1j}(\theta) = \frac{1}{2} \left( \frac{\partial \theta}{\partial x_j} + \frac{\partial \theta}{\partial x_1} \right) \) and let

\[
\|u\|^2_{R, \omega} = \|\theta\|^2_{E(\omega)} + \|\theta - w\|^2_{0, \omega}, \quad u = (w, \theta), \quad w \in H^1(\omega), \quad \theta \in (H^1(\omega))^2.
\]

Theorem B.1. There is a constant \( C \) depending only on \( \omega \) such that for any \( \theta \in [H^1(\omega)]^2 \)

\[
\inf_{\theta} \left\{ \|\theta_1 - a - bx_2\|^2_{1, \omega} + \|\theta_2 - c + bx_1\|^2_{1, \omega} \right\} \leq C\|\theta\|_{E(\omega)}
\]

(B.1)

\[
\inf_{\theta} \|w - (a + bx_1 + cx_2 + dx_1 x_2)\|_{H^1(\omega)} \leq C\|\theta\|^2_{R, \omega}.
\]

(B.2)

Proof. Inequality (B.1) follows immediately from the Korn inequality for plane elasticity, see [19]. Inequality (B.2) follows from (B.1).

Lemma B.2. There exists a constant \( C \) depending on \( \omega \) such that for any \((w, \theta) \in [H^1(\omega)]^3\)

\[
\|w\|^2_{1, \omega} + \|\theta\|^2_{1, \omega} \leq C\|\theta\|^2_{R, \omega} + \int_{\partial \omega} w^2 \, ds.
\]

Proof. We apply the standard contradiction argument. If the assertion is not true, there is a sequence \((w_n, \theta_n)\) such that

\[
\|w_n, \theta_n\|_{1, \omega} = 1
\]

and
\[ \|\theta_n\|_{E(\omega)} \to 0, \]
\[ \|\theta_n - \nabla \omega\|_{n_0, \omega} \to 0, \quad \int_{\partial \omega} \omega^2 ds \to 0 \]
as \( n \to \infty \). Then by Theorem B.1, \( \{\theta_n\} \) contains a subsequence (which we denote once more by \( \{\theta_n\} \)) such that \( \theta_n \to (a-bx_2, c+bx_1) \) in \( H^1(\omega) \). Further, since \( \|\theta_n - \nabla \omega\|_{n_0, \omega} \to 0 \) there is another subsequence (once more denoted by \( \{\theta_n, \omega_n\} \)) so that \( \omega_n \to \omega \) in \( H^1(\omega) \). Hence \( b = 0 \) and \( \omega = ax_1 + cx_2 + d \).

Because \( \int \omega^2 ds \to 0 \) we get \( a = c = d = 0 \) which contradicts the assumption \( \|\omega_n, \theta_n\|_{1, \omega, 1} = 1 \).

We immediately get

Theorem B.2. There exists a constant \( C \) depending only on \( \omega \) such that for any \( u = (w, \theta) \in H^1_0(\omega) \times [H^1(\omega)]^2 \)

\[ \|\omega\|_{1, \omega}^2 + \|\theta\|_{1, \omega} \leq C|u|^2_{R, \omega}. \]

Let us now consider a family \( \mathcal{F} = \{\omega\} \) of Lipschitz bounded domains. The family will be called regular if there is a (uniform) constant \( C \) so that (B.3) holds for all \( \omega \in \mathcal{F} \).

Let us now consider a special family of domains. Let \( \omega[0] \) be a unit circle and \( \omega[n] \) be a sequence of regular \( n+3 \)-polygons such that

\[ \omega[n] \subset \omega[n+1] \subset \omega[1] \subset \omega[n+1] \subset \omega[0], \]

and

\[ \omega[n] \to \omega[0] \text{ as } n \to \infty \]
in the sense that for any \( x \in \omega[0] \) there is \( n(x) > 0 \) such that \( x \in \omega[n] \) for all \( n > n(x) \). We let \( \mathcal{F}_0 = \{\omega[0], \omega[1], \omega[2], \ldots\} \).
Theorem B.3. The family $\mathcal{S}_0$ is a regular family of domains and hence there exists $\omega > 0$ such that

$$\|w\|_1^2 + \|\theta\|_1^2 \leq C|\omega|_1^2$$

for any $\omega = (w,\theta) \in H_0^1(\omega^1) \times H^1(\omega^1)^2$, $n = 0,1,2,...$.

Proof. For $n > n_0$ the $\omega^n$ are star shaped domains and

$$\partial\omega^n = \{(x_1,x_2) : x_1 = \rho_n(\theta)\cos \theta,$$

$$x_2 = \rho_n(\theta)\sin \theta, \ 0 \leq \theta \leq 2\pi\},$$

where $\rho_n(\theta) \to 1$ and $\rho_n'(\theta) \to 0$ uniformly. Let $Q_n$ be the one-to-one map of $\omega^n$ onto $\omega^0$ defined by

$$Q_n(\rho(\theta)\cos \theta,\rho(\theta)\sin \theta) = (\rho(\theta)\cos \theta,\rho(\theta)\sin \theta) \text{ for } \rho(\theta) \leq 1/2,$$

$$= \left[\frac{1}{2} \rho_n(\theta)-(1/2) + \frac{1}{2}\right] \cos \theta,$$

$$\left[\left[\frac{1}{2} \rho_n(\theta)-(1/2) + \frac{1}{2}\right] \sin \theta\right] \text{ for } \rho(\theta) > 1/2.$$

If $Q_n(x_1,x_2) = (\xi_1,\xi_2)$ then we have $\xi_1 = \xi_1^n(x_1,x_2)$, $\xi_2^n = \xi_2^n(x_1,x_2)$,

$$x_1 = x_1^n(\xi_1,\xi_2), \ x_2 = x_2^n(\xi_1,\xi_2) \text{ and } \xi_1^n \to x_1, \ \frac{\partial \xi_1^n}{\partial x_j} \to \delta_{ij}, \ x_1^n \to \xi_1,$$

$$\frac{\partial x_1}{\partial \xi_j} \to \delta_{ij}, \ 1,j = 1,2 \text{ as } n\to\omega, \text{ uniformly with respect to } (x_1,x_2) \in \omega^n$$

and $(\xi_1,\xi_2) \in \omega^0$. Let $u = (w,\theta) \in H_0^1(\omega^n) \times H^1(\omega^n)^2$ and let

$$\bar{u} = (\bar{w},\bar{\theta}), \ \bar{u}(\xi_1,\xi_2) = u(x_1(\xi_1,\xi_2),x_2(\xi_1,\xi_2)).$$

Then $\bar{u} \in H_0^1(\omega^0) \times H^1(\omega^0)^2$ and by Theorem B.2 we have

$$\|\bar{w}\|_1^2 + \|\bar{\theta}\|_1^2 \leq C|\bar{u}|_1^2$$

$$\|\bar{w}\|_1^2 + \|\bar{\theta}\|_1^2 \leq C|\bar{u}|_1^2$$

for any $\bar{w},\bar{\theta} \in \omega^0$. Therefore, we have

$$\|w\|_1^2 + \|\theta\|_1^2 \leq C\|\bar{u}\|_1^2$$

for any $\omega = (w,\theta) \in H_0^1(\omega^1) \times H^1(\omega^1)^2$, $n = 0,1,2,...$.
and also

$$\|w\|_{1, \omega[n]} = \|w\|_{1, \omega[n]}^{(1+\alpha(1))},$$

$$\|\theta\|_{1, \omega[n]} = \|\theta\|_{1, \omega[n]}^{(1+\alpha(1))},$$

$$|\tilde{u}|_{R, \omega[n]} = |u|_{R, \omega[n]} + \alpha(1)(\|w\|_{1, \omega[n]} + \|\theta\|_{1, \omega[n]}),$$

as $n \to \infty$. Hence

$$\|w\|_{1, \omega[n]}^{2} + \|\theta\|_{1, \omega[n]}^{2} \leq C(|u|_{R, \omega[n]}^{2} + \alpha(1)(\|w\|_{1, \omega[n]}^{2} + \|u\|_{1, \omega[n]}^{2})).$$

From this we see that for $n > n_0$ the family is a regular one. Using Theorem B.2 we then see that the whole family $\mathcal{F}_0$ is regular. \hfill \Box
Appendix C. A projection theorem.

**Theorem C.1.** Let $H$ be a Hilbert space, let $\{H_n\}$ and $\{K_n\}$ be sequences of closed subspaces of $H$ such that $H_n \subset H_{n+1}$ and $K_n \supseteq K_{n+1}$, $n = 1, 2, \ldots$, and let

$$H_0 = \bigcup_{n=1}^{\infty} H_n \quad \text{and} \quad K_0 = \bigcap_{n=1}^{\infty} K_n.$$  

Further, let $P_n$ and $Q_n$, respectively $P_0, Q_0$, be orthogonal projections onto $H_n$ and $K_n$ respectively $H_0, K_0$. Then for any $u \in H$,

$$\|P_n u - P_0 u\| \to 0,$$

$$\|Q_n u - Q_0 u\| \to 0$$

as $n \to \infty$.

**Proof.** Observe first that $\|Q_{n+1} u\| = \|Q_{n+1} Q_n u\| \leq \|Q_n u\|$, so $\|Q_n u\| \to q > 0$ monotonically. Further

$$\|Q_n u - Q_{n+j} u\| = \|Q_n u\|^2 - 2(Q_n u, Q_{n+j} u) + \|Q_{n+j} u\|^2 = \|Q_n u\|^2 - \|Q_{n+j} u\|^2,$$

so $\{Q_n u\}$ is a Cauchy sequence. So $Q_n u \to v$ and $v \in K_n$ for all $n$. Hence $v \in K_0$ and since $(v,w) = \lim_{n \to \infty} (Q_n u, w) = \lim_{n \to \infty} (u, Q_n w) = (u, w)$ for all $w \in K_0$, it follows that $v = Q_0 u$.

Let us now consider the projection operator $I - P_n = \tilde{Q}_n$. Then $\tilde{Q}_n$ projects $H$ onto $H_n^1$ and $H_n^1 \supseteq H_{n+1}^1$. Hence $\tilde{Q}_n u = u - P_n u \to u - v \in \bigcap_{n=1}^{\infty} H_n^1$. So $P_n u \to v \in H_0$ and by the same argument as before, $v = P_0 u$. \qed
References

The Laboratory for Numerical analysis is an integral part of the Institute for Physical Science and Technology of the University of Maryland, under the general administration of the Director, Institute for Physical Science and Technology. It has the following goals:

- To conduct research in the mathematical theory and computational implementation of numerical analysis and related topics, with emphasis on the numerical treatment of linear and nonlinear differential equations and problems in linear and nonlinear algebra.

- To help bridge gaps between computational directions in engineering, physics, etc., and those in the mathematical community.

- To provide a limited consulting service in all areas of numerical mathematics to the University as a whole, and also to government agencies and industries in the State of Maryland and the Washington Metropolitan area.

- To assist with the education of numerical analysts, especially at the postdoctoral level, in conjunction with the Interdisciplinary Applied Mathematics Program and the programs of the Mathematics and Computer Science Departments. This includes active collaboration with government agencies such as the National Bureau of Standards.

- To be an international center of study and research for foreign students in numerical mathematics who are supported by foreign governments or exchange agencies (Fulbright, etc.)

Further information may be obtained from Professor I. Babuška, Chairman, Laboratory for Numerical Analysis, Institute for Physical Science and Technology, University of Maryland, College Park, Maryland 20742.
