A Command and Control Wargame to Train Officers in the Integration of Tactics and Logistics in a Field Artillery Battalion

Due to peacetime training limitations, the integration of tactics and logistics as it relates to the command and control of a field artillery battalion cannot be easily practiced. This thesis presents a computer assisted wargame which will give battalion staff officers some experience in dealing with this shortcoming. The wargame emphasizes the decision maker in the command and control system. Specifically, this wargame forces the decision maker to consider numerous tactics/logistics interface issues and then make a series of command and control type decisions. At the end of each game, the player's performance is evaluated in terms of howitzer availability time, casualty rates, vulnerability rates, and ammunition optimization. The wargame itself is highly flexible and is capable of being played in support of a full scale battalion command post exercise or during weekly officer professional development time.

ABSTRACT

Due to peacetime training limitations, the integration of tactics and logistics as it relates to the command and control of a field artillery battalion cannot be easily practiced. This thesis presents a computer assisted wargame which will give battalion staff officers some experience in dealing with this shortcoming. The wargame emphasizes the decision maker in the command and control system. Specifically, this wargame forces the decision maker to consider numerous tactics/logistics interface issues and then make a series of command and control type decisions. At the end of each game, the player's performance is evaluated in terms of howitzer availability time, casualty rates, vulnerability rates, and ammunition optimization. The wargame itself is highly flexible and is capable of being played in support of a full scale battalion command post exercise or during weekly officer professional development time.

I. DESCRIPTION OF THE PROBLEM

A. INTRODUCTION

In the United States Army, combat-arms-type units have a very difficult time finding ways to conduct fully realistic training. In a peacetime environment there are many factors which inhibit realistic training. Budgetary constraints limit the scope and duration of training as well as minimize the amount of ammunition expended. Safety considerations limit intensity and realism in training. And, the lack of adequate training areas compresses the size of the "training battlefield" so that training does not take place over realistic distances. The implication to those concerned with the command and control of combat units is that there is very little "hands on" experience available in the integration of tactics and logistics as it relates to the command and control of these units. This lack of hands on experience by our officers is a potential deficiency which deserves some attention.

In order to address this deficiency, there are many options available. These options range from training through "field training exercises" (FTX) down to classroom instruction. An FTX would theoretically provide the best situation for training the tactics / logistics interface. However, FTXs rarely provide more than a start point for
understanding the tactics / logistics interface issues. This is true due to budget constraints, safety considerations, training area limitations, and low peace time ammunition consumption rates. In short, we are never faced with the problems of moving enough ammunition to keep up with tactics or slowing tactics to keep pace with ammunition resupply rates because we rarely fire ammunition on combined arms exercises (at least not at a realistic rate).

Classroom instruction can serve as an introduction to the issues related to the integration of tactics and logistics but it lacks the critical element of hands-on experience. An individual must confront and solve these type of problems for himself in order to be effective at the beginning of the next war.

The next best thing to an FTX is a command post exercise (CPX). In the CPX, all but the command and control elements are played notionally. Normally, some type of wargame is played at a remote location and then the various command posts must perform their wartime functions in accordance with the wargame scenario. In most cases, when CPX's are run by higher level headquarters, the resolution is such that very little training on the integration of tactics and logistics takes place at the battalion level. In fact, the nature of the tactics / logistics problem is such that it is very difficult for a wargame to provide an environment which
trains officers in the integration of these functions. Most wargames either emphasize tactics or logistics but not both. This is due to the fact that it requires much more detail than can be generated under normal conditions in a manually run wargame.

B. WHAT IS MEANT BY THE INTEGRATION OF TACTICS AND LOGISTICS?

According to Army Field Manual 100-5...

Commanders must plan tactics and logistics concurrently to insure that the tactical scheme of maneuver and fire support are logistically supportable. They consider the constraints that Combat Service Support planners identify. They modify unsupportable plans or accept the risks involved. [ref. 1: p. 5-1]

This refers primarily to the integration of tactics and logistics in the planning of operations. However, the integration process does not stop there. During the conduct of operations, the integration of tactics and logistics is a continuous process which is driven by factors such as expenditure rates, casualty rates, supply availability, supply transportation capacity, and the tactical situation. All of these factors must be carefully managed in order to conduct a cohesive operation. Failure to integrate tactics and logistics can result in failure to accomplish the unit’s overall mission.

C. SCOPE OF THE THESIS

This thesis describes the use of a battalion level, computer assisted wargame, played by the battalion
operations and logistics staff sections, to train officers in the integration of tactics and logistics as it applies to the command and control of a field artillery battalion. Limiting the discussion to the command and control of a field artillery battalion was done only to provide a manageable start point for exploring the larger issue of training officers in the integration of tactics and logistics. The field artillery battalion is a logical choice as a start point because of the field artillery's dependence on extremely large quantities of bulk ammunition. In wartime, this dependence will dictate the movement of firing batteries and the rate at which firing batteries can shoot. Ammunition trucks will become a scarce resource that needs to be carefully managed to ensure optimum ammunition resupply as well as survivability. Therefore, in addition to consideration of howitzer vulnerability thresholds, the tactical situation, movement plans, fire plans, and casualty projections, the commander and his staff will also have to consider unit distribution plans or point distribution plans, potential limitations on firing rates, ammunition truck movement plans, and truck vulnerability thresholds.

This thesis presents a wargame that attempts to capture these concepts in a form which will provide a learning environment for those tasked with the command and control of a field artillery battalion. The wargame is only computer assisted. It is important to note that the "essential
ingredients of any command and control system...are the commanders or decision makers themselves." [ref. 2: p. 618] The computer portion of the wargame will only provide relevant information to the decision maker, execute his decisions, and keep track of the game’s statistics. At the end of the game, a measure of effectiveness (MOE) will be computed which will provide an assessment of the player’s performance. The MOE is based on a computation of the howitzer availability time, the amount of time spent at a critical vulnerability level, the amount of time lost due to casualties, and the amount of time spent short of sufficient amounts of ammunition. This will force the decision maker to plan ahead and to consider all of the relevant concepts in order to maximize howitzer availability time, minimize vulnerability, minimize casualties, and optimize ammunition resupply. The intent of the wargame is to provide an environment in which officers can learn to consider the factors which are critical to the integration of tactics and logistics.

In order to build such a wargame, an analysis of the architecture of field artillery battalion is required. This analysis is the topic of Chapter II. Using this analysis, the approach taken to design a wargame which trains officers in the integration of tactics and logistics as it relates to the command and control of a field artillery battalion is discussed in Chapter III. Chapter IV describes the
processes used by the computer to derive some of the more important aspects of the wargame. A user's manual for the wargame is provided in Chapter V. Finally, Chapter VI discusses suggested enhancements and potential uses of the wargame.
II. THE FIELD ARTILLERY BATTALION SYSTEM / ARCHITECTURE

A. INTRODUCTION

Before building a wargame that simulates the operations of a field artillery battalion, it is critically important to analyze the battalion in order to determine how it works. More specifically, it is important to know not only the internal interactions which take place within the battalion, but also the interactions the battalion has with external elements. It is important to understand the battalion's environment and its mission. More importantly, it is important to understand how the environment affects the battalion's ability to achieve its goals and if there are any other constraints which may hinder the achievement of these goals.

One proven method of analysis is through the use of the "Systems Approach." A system, as defined by Professor James G. Taylor of the Naval Postgraduate School, is a "collection of elements which combine together to form a whole in order to accomplish a goal." [ref. 3] The systems approach provides a method of developing the system by considering the system's goals, the environment, the mission, the resources, and the management [ref. 4: p. 44].

To supplement the systems approach, the system architecture provides a depiction of the "interconnections
between elements of the system. Interconnections can be based on time, functional, informational or spatial relationships." [ref. 4: p. 126]

Through the use of both the systems approach and the systems architecture, the field artillery battalion can be thoroughly analyzed. A conscious effort has been made to separate the analysis using the systems approach and the systems architecture. It was felt that it would be better to first conduct a written analysis of the battalion using the systems approach and then fill in between the lines by letting each graphical portrayal of the system architecture say "a thousand words". This analysis will be helpful in determining which aspects of the battalion will be germane to the design of the wargame and which system characteristics can be ignored.

B. FIELD ARTILLERY MISSION

The mission of the field artillery is to "destroy, neutralize, or suppress the enemy by indirect fires and to integrate all fire support into combat operations. Successful execution of this mission demands effective integration of field artillery fires into the scheme of maneuver and swift, exact, execution from the time a target is acquired until ordnance is delivered on target." [ref. 5: p. 1-1] Field Manual 6-20-1, FIELD ARTILLERY CANNON BATTALION OPERATIONS, goes on to say that in order for the
battalion to support maneuver forces on the battlefield successfully, it must survive to perform the following 10 basic tasks:

1. **Target Acquisition**—Detecting and engaging targets that threaten maneuver elements of the supported brigade.

2. **Meteorology, Survey, Technical Fire Direction**—The battalion operations officer (S3) insures that fire direction centers (FDC) have the information they need to conduct effective fire direction.

3. **Fire Planning**—Field artillery fires are planned to achieve one of three effects on the target: suppression, neutralization or destruction. The desired effect will be determined by the supported unit commander, the fire support coordinator (FCOORD), or the fire direction officer.

4. **Tactical Fire Control**—Tactical fire direction includes selection of rounds, shell/fuze combinations, and designation of units to fire.

5. **Plans and Orders**—Command and control of the field artillery cannon battalion is established through the assignment of tactical missions.

6. **Positioning**—The planning for the selection of any position must include consideration of communication requirements and combat service support in addition to the mission, terrain, and tactical situation.

7. **Reconnaissance**—Reconnaissance is performed to select the best battalion and battery positions, march routes, start and release points, command posts, observation posts, and communication sites, and to analyze the terrain where the battle will be fought. Prior to or concurrent with reconnaissance, the field artillery commander/S3 should coordinate with the maneuver commander/S3 to determine what areas maneuver units plan to occupy. Mutual agreement must be established to make the best use of the available terrain.

8. **Displacement**—Field artillery battalions must frequently displace to provide continuous fire support to maneuver units. There are three general ways that a field artillery battalion moves; by unit displacement,
by echelon, and by battery. In unit displacement, the entire battalion moves at once and no units are available to provide fire support. In displacement by echelon, some portion of the battalion moves and sets up in the next position and then the other portion of the battalion moves. In displacement by battery, one battery at a time displaces. This method provides the maximum amount of fire support at any given time but it is sometimes too slow to keep up with maneuver.

9. Communications--The cannon battalion commander must rely on communications to control elements of his command, gather information, distribute intelligence, and coordinate fire support. The primary means of communications in the cannon battalion are radio and wire.

10. Combat Service Support (CSS)--CSS is the process of keeping the maximum number of weapon systems operational. The support functions and operations in the battalion by the personnel officer (S1), logistics officer (S4), or any other supervisor must be closely coordinated with tactical operations. A continuous exchange of information among CSS coordinators, the S3, and battery commanders is essential to the success of both tactical and logistical plans. [ref. 5]

The mission of the field artillery and its implied tasks are critical to understanding how the field artillery battalion works and how to build a wargame which simulates the battalion. The mission can be broken into two parts. The first is the requirement to be capable of delivering timely, accurate, and effective fires and the second is to provide those fires in a manner which supports the overall scheme of maneuver. The ten basic tasks are the implied tasks which any field artillery unit must be able to perform in order to accomplish the field artillery mission. These tasks are important because they represent functions that the wargame will have to be able to perform to varying degrees depending on the mission and goals of the wargame.
The field artillery mission clearly implies that the field artillery battalion is a part of a larger system which, among other things, dictates the scheme of maneuver which must be supported. The mission also implies that in order to provide swift, exact indirect fires, much coordination and interaction with external elements must take place in order to ensure that the artillery can range the enemy, has enough ammunition on hand to support the operations, and has coordinated positions to which it can displace. Finally, the mission implies that the unit must be able to survive to perform all of these tasks.

C. GOALS

The mission and its implied tasks can be boiled down to several goals. These goals are necessary because they help to quantify the degree to which the unit is effective in the accomplishment of its mission. They also help to further describe the system and the positive and negative motivations which are inherent in the system. In this respect, an analysis of the goals will be very useful to the design of the wargame and particularly to the design of any MOEs which may be necessary.

The goals were chosen to address the mission and its implied tasks. They are stated in quantifiable terms. These goals are closely related and some could actually be considered as sub-goals to other goals. However, they have
been separated into different goals based upon the fact that there are specific command and control actions which can be taken to optimize each goal. In many cases these actions serve to oppose other goals and so a set of tradeoffs must be considered. The four goals are described below.

1. **Maximize Availability Time**

   First and foremost, the battalion must be able to support the maneuver units. This means that the battalion must have the maximum number of cannons in a firing status for the maximum amount of time. It also means that the firing units must always have ammunition to fire and that they should minimize the number of tubes lost to maintenance or enemy fire.

   In operational terms, it means that firing units must displace as little as possible without letting the enemy get out of range and without letting themselves get too vulnerable to enemy detection. This goal can be measured in tube hours, i.e., the sum of the total number of hours each tube is capable of providing fire support.

2. **Minimize Vulnerability**

   A firing unit becomes more vulnerable to enemy detection in two ways. First, the longer a unit is in position, the more likely it is that it has been located by aerial reconnaissance. Second, the more rounds a firing battery fires out of a position, the more likely that unit
has been located by enemy counter-battery radar. These probabilities of detection can be determined from probability of detection versus time and versus "rounds fired" curves, respectively. These probabilities can be combined to derive a vulnerability factor.

In operational terms, a commander must be willing to accept some degree of vulnerability. Some positions are more vulnerable than others due to the amount of cover and concealment available. A vulnerability threshold can be specified by a commander in terms of rounds fired out of a position when time in the position is less than some specified maximum allowable time in that position. A unit should move when it reaches the commander's vulnerability threshold so that its vulnerability level is reset at zero. Many times, due to the tactical situation or due to a lack of prior planning, the commander cannot move a unit when it reaches the commander's vulnerability threshold. It is the time spent above the vulnerability threshold that the commander wants to minimize. This goal can be measured in the number of tube hours spent above the vulnerability threshold.

3. Minimize Casualties

Casualties can be incurred both in positions and during displacement. In operational terms, a commander can minimize casualties by moving often thereby minimizing vulnerability. Or, he may take the safest but not
necessarily the shortest routes on displacements. This goal to conserve assets for both current and future operations must be balanced against the goal to maximize availability time. This goal can be measured in terms of the tube / truck / equipment / personnel time lost during the operation due to casualties.

4. Optimize Logistics Operations

Logistics operations also experience vulnerability and casualties and therefore goals two and three apply to logistics units. More importantly, logistics units are critical to the attainment of the first goal. Fire units which are low on ammunition or fuel can not adequately support maneuver forces and fire units which are out of those supplies are not available to support maneuver units.

In operational terms, there are many different forms of resupply operations. The battalion trains can deliver supplies to the unit (unit distribution) or it can deliver the supplies to a point where the fire units will have to go to pick up their supplies (point distribution). The trains can bundle their trucks into convoys to pick up and deliver supplies or they can use the "trickle" method to pick up and deliver supplies by sending as few as one truck at a time as the trucks become available. The method used depends on the tactical situation, the enemy situation, the terrain and the level of training of the units.
Optimization refers to making the most efficient use of the supplies and the resupply assets in order to ensure accomplishment of the field artillery mission. This goal can be measured in terms of the amount of time firing units spend critically short, or out of, critical supplies.

This analysis of the field artillery battalion's goals and especially the statements of the goals in operational terms tells us a lot about the internal operation of the battalion and about what motivates operational decisions. These motivating factors must also be present in the wargame in order to have any true training value.

D. ENVIRONMENT

The field artillery battalion exists in an environment consisting of both friendly and hostile elements. The friendly environment can also be divided. It consists of command relationships and support relationships.

Command relationships refer to the fact that the field artillery battalion is commanded by the division artillery which is commanded by the division and the fact that the maneuver battalions are commanded by the maneuver brigade which is in turn commanded by the division and finally that the support battalions are commanded by the division support command which is also commanded by the division. In short, there is no command relationship between the field artillery battalion and the maneuver units or the support units.
Support relationships refer to the relationship that does exist between the field artillery battalion and the maneuver units and the support units. The direct support field artillery battalion has a mission to provide close support to a maneuver brigade. With this mission, according to Field Manual 6-20-1, comes the requirement to provide first priority on calls for fire to the brigade and to provide fire support coordinating personnel to the brigade. The division artillery assigns missions to the field artillery battalion. By the same token, the division support command assigns missions to its subordinate units to provide service support to various divisional units. In this manner, the field artillery battalion will have a support unit assigned to provide supplies to support its mission.

The hostile side of the environment refers to the fact that the enemy exists to prevent accomplishment of the battalion’s mission. It does this by producing casualties, by interdicting critical supplies, disrupting the plan, and disrupting command, control and communications. There are many forms of hostile acts performed by the enemy. Any wargame must consider this aspect of the environment.

Another aspect of the environment is the fact that all the elements of the system and the elements of the external environment exist on the battlefield. They are separated by considerable distances and must move frequently in order to
stay in the battle. They are positioned so as to best facilitate accomplishment of their mission and to assure survivability. They are positioned on terrain which provides some degree of cover and concealment and which may or may not facilitate communications with other elements of the system and environment.

Finally, a discussion of the environment would not be complete without considering what Clausewitz called "FRICTION." [ref. 6] This refers to the fact that operations never occur as planned. There are many reasons for plans going wrong which are beyond the control of the commander. All of them are lumped together and called friction. This requires commanders to be flexible. They must be able to modify plans quickly and issue effective fragmentary orders.

An understanding of the environment is necessary for a full understanding of the field artillery battalion system. It is also necessary to include the critical aspects of the environment in the wargame.

E. RESOURCES

The battalion’s resources primarily include its people, its equipment, and its supplies. Its people include its leaders and its soldiers. They are trained and work together as a part of a team. They operate the equipment which helps to accomplish the mission. People are the
battalion’s most important resource. It takes people to operate the equipment and to use the supplies. It takes trained people who can work together as a cohesive unit to accomplish the battalion’s mission.

The field artillery battalion’s most critical equipment includes its weapon systems, fire direction systems, and supply trucks. All are critical to accomplishment of its mission.

The field artillery battalion’s most critical supplies are food, fuel, and ammunition. All are critical to accomplishment of its mission. Units establish required supply rates (RSR) which tell higher level units how much ammunition is required to accomplish the mission. The higher level unit then establishes the controlled supply rate (CSR) which is based upon how much ammunition is available. If the CSR is less than the RSR, then the unit must curtail operations to avoid exceeding the CSR.

Resources can be easily represented by computer simulation. However, the manipulation and expenditure and conservation of resources to accomplish the mission, which is the subject of the next paragraph, is best left to the human interaction portion of the wargame.

F. MANAGEMENT

In the military, the commander is responsible for all that his unit does or fails to do. However, he has a staff
to assist him in the two primary management functions of planning and controlling the battalion. The commander alone, however, must provide leadership for the battalion. His leadership serves to inspire and motivate his soldiers and it provides direction for his subordinate units and his staff. In addition to providing direction, the commander must approve all plans and issue all orders in his name. These aspects of command are very difficult to simulate using computers and are best represented in wargames by the human players themselves.

Staffs conduct planning under the commander’s guidance. The S3 is responsible for incorporating all of the staff estimates and determining the recommended course of action. The commander then either approves or selects his own course of action. The staff then prepares the plans to execute that course of action. The plan becomes an order when issued to subordinates with an execution time. Planning is a complex process which requires much training. It is therefore suitable for the human element in a wargame.

Controlling refers to the process of monitoring operations to ensure that they are being carried out within the commander’s intent. It also refers to monitoring the overall tactical situation to determine if the plan is still appropriate. If it is not appropriate, it involves modifying the plan and issuing fragmentary orders.
Controlling is a continuous process which requires the commander and his staff to monitor the battalion's environment and resources and to make the tradeoffs implied in the battalion's goals, all in order to accomplish the battalion's mission. This complex process is especially appropriate for the human interaction portion of the wargame.

G. ARCHITECTURAL LINK DEPICTIONS

The discussion of the field artillery battalion thus far using the systems approach has been very useful in understanding the battalion so that an effective wargame can be designed. Graphical portrayal of the discussion in the form of the battalion's system architecture will now be useful in clarifying and adding to that discussion.

Systems architectures can be depicted in several different ways depending on the perspective desired. For the purposes of this thesis, functional, spatial, informational, and time depictions will be used. A description of each can be found in this section.

1. Functional

"Functional architecture describes the technical structure of large systems." [ref. 7: p. 2.4] Figure 2.1 is a functional depiction of the divisional supersystem.
Figure 2.1 Divisional Super-System
Everything outside of the field artillery battalion itself is a part of the battalion's environment. Boxes within other boxes indicate command relationships. Arrows indicate support relationships.

Figure 2.2 is a functional depiction of the field artillery battalion. Again, boxes within other boxes indicate command relationships. However, in this case the primary function of each element is listed next to its box.

2. Spatial

Spatial architecture depicts the physical relationship of the elements in the system. Figure 2.3 is a spatial depiction of the field artillery battalion system. Since a direct support field artillery battalion normally supports a maneuver brigade, the brigade's battlefield geometry is depicted. The firing batteries must be able to project approximately two-thirds of their range into enemy territory. Therefore, the howitzers are found four to eight kilometers behind the front line of troops (FLOT). Normally, all three batteries support the entire brigade rather than one battery per maneuver battalion. Therefore, batteries are positioned where they can best support the entire brigade in accordance with the battalion's battery displacement plan.

The battalion tactical operations center (TOC) must be positioned farther back for survivability. But it must be in close proximity to the supported brigade headquarters.

FIELD ARTILLERY BATTALION

SPACIAL ARCHITECTURE

Figure 2.3 Field Artillery Battalion Spatial Architecture
and it must be able to communicate with the firing batteries and the brigade TOC.

The battalion trains are located even farther to the rear for survivability and for ease of coordination with support units. The dotted lines which emanate from the trains indicate that resupply convoys are constantly on the road.

The spatial architecture is important because it puts the physical relationships of the elements in perspective. An appreciation of the distances involved is necessary to the wargame to simulate the times required for events to transpire.

It is also important to note that Figure 2.3 is only a snapshot of the system at a particular instant in time. Elements of the system must continuously move in order to perform their missions and enhance survivability.

3. Information

Information architecture is especially important to the design of the wargame because it depicts the information flow both within the system and to external elements. Figure 2.4 depicts this flow for the battalion and its environment. Only the most critical elements of information have been depicted.

Implied in Figure 2.4 is the fact that if information flows between two elements, then a communications system must exist between them. This figure
FIELD ARTILLERY BATTALION
INFORMATION ARCHITECTURE

Figure 2.4 Field Artillery Battalion Information Architecture
does not show the communications nets. It only relates that communications exists between the elements. The habitual flow of information between elements leads to the use of various message formats for different types of information and it leads to standard operating procedures which dictate when and how the messages will be sent.

Also depicted on Figure 2.4 with a dotted line is the system boundary. Everything within the dotted line is in the field artillery battalion system. Everything outside the dotted line is external to the system. The lines of communications that cross the boundaries are then external communications and the lines of communications within the boundaries are internal communications.

The information architecture is extremely important to the analysis as it relates to the design of the wargame. The primary problem will be which information is needed in the wargame and which information is not necessary to accomplish the goals of the wargame. Dividing the communications into internal and external communications also will be helpful in arriving at a solution to the problem.

4. Architectural

Architectural depictions based on time relationships help to place events in their natural order. In a complex system such as the field artillery battalion, this can be very difficult to do. Schedules of events are not
appropriate because events do not usually happen at a specific time. It is even difficult to attempt to put events into a chronological order without assigning specific times. The best that can be done is to use the concepts of time based depictions of architecture to analyze the combat process.

Figure 2.5 is the Conceptual Combat Operations Process Model [ref. 8: p. 27]. By avoiding specific events and analyzing the generic process instead, an understanding of the logical order of the component parts of any operation can be gained. It is important to note that as a generic model, it applies to tactical operations, logistical operations, and applies equally well to both current operations and future operations plans.

Figure 2.5 implies that combat operations consist of a cyclic process which is stimulated by the environment and leads to an attempt to understand the environment. This is followed by the formulation of alternative courses of action, guidance from higher headquarters, and ultimately a decision to take some action which relates to the perception of the environment. This decision is then sent to subordinate elements and is executed. This in turn has some impact on the environment and changes the stimulus which caused the action in the first place and the process repeats itself.
CONCEPTUAL COMBAT OPERATIONS
PROCESS MODEL

Figure 2.5 Conceptual Combat Operations Process Model
This model gives structure to the wargame by providing a logical order to the functions which must be performed both by the computer program and the human interaction portions of the game.

II. SUMMARY

In order to build a wargame that trains officers in the integration of tactics and logistics, an analysis of the field artillery battalion is necessary. Use of the systems approach provides a structure for this analysis so that all of the important aspects of the battalion can be considered. The understanding of the field artillery battalion which was gained through this analysis is critical to the design of the wargame. The next chapter will discuss the approach taken in the design of this wargame.
III. THE CONCEPTUAL APPROACH

A. INTRODUCTION

This section is not intended to provide detailed, technical design criteria for the wargame. Rather, it is intended to provide the approach taken to resolve many of the issues which arose while conceptualizing this wargame.

It is important to differentiate between the field artillery battalion system and the wargame. The wargame can be considered a system unto itself. Therefore, the best way to look at the conceptual approach is by using a system view of the wargame. In many cases, the best approach to take for certain system aspects of the wargame is to simply simulate the same system aspects from the field artillery battalion. In other cases, there are some important differences. Therefore, specific references will be made to the wargame system and to the battalion system in order to avoid confusion.

As with the battalion, a discussion of the mission, goals, environment, resources, and management follows. These aspects, along with a discussion of some of the architectural depictions, will provide the vehicle for a complete discussion of the approach taken for the design of this wargame.
B. MISSION OF THE WARGAME

The mission of this wargame is to train officers in the integration of tactics and logistics as related to the command and control of a field artillery battalion. There are several implied tasks which are necessary for the wargame to accomplish this mission. The wargame must be oriented toward the command and control elements of the battalion. Therefore, the players will consist of an operations and intelligence (O&I) staff section, a logistics (S4) staff section, and a battalion commander. It must require the players to weigh all of the tradeoffs involved in integration of tactics and logistics. Special emphasis must be given to those areas which are not normally experienced in a peacetime training environment. Since the mission is to train officers, the wargame must provide feedback to the officers so that good decisions are reinforced and poor decisions are penalized. This can be done through the use of a measure of effectiveness which evaluates the player's performance. Finally, the wargame must be able to provide a realistic representation of the field artillery battalion system. This means that the field artillery mission should be central to the wargame's design. Each of the artillery's ten implied tasks must be performed by the wargame to varying degrees.
1. **Target Acquisition**

This function will not be explicitly played in the first iteration of the wargame. Targets will be provided to the battalion TOC. All other firing will be done at some predetermined rate depending on the tactical situation.

2. **Meteorology, Survey, Technical Fire Control**

These functions also will not be explicitly played as a part of this wargame. This is due to the fact that these functions are not germane to the wargame’s mission of training officers in the integration of tactics and logistics. These functions relate to the computation of actual firing data.

3. **Fire Planning**

This function must be performed as a part of the wargame at a tactical level since it occupies a significant portion of the operations and intelligence section’s time. More importantly, it must be done with the logistics situation in mind. It requires an analysis of the CSR in order to avoid firing too many rounds.

4. **Tactical Fire Control**

Some battalion level fire missions will be useful for causing the O&I section to determine the number of rounds to fire on a given target and the number of fire units. However, the level of resolution need not include the various shells and fuzes in the wargame’s first version. Once again, this will cause the O&I section to weigh the
desire for effects on target against the logistics situation.

5. Plans and Orders

These functions represent the essence of the command and control / battle management portion of the wargame. They will be performed by the players as they would actually perform them in a real wartime environment. The game will begin with a hard copy of the supported maneuver unit's operations order. The O&I section and the logistics section will then begin planning, develop an order, and then, using the computer, send the order to the units to execute. The computer program portion of the wargame is responsible for the execution of all orders.

6. Positioning

This function is also extremely important to the design of the wargame. All positions must be coordinated with the maneuver unit that owns the land. Positions must also be coordinated with the resupply plan.

7. Reconnaissance

Reconnaissance must be performed within the wargame so that realistic plans can be made. At the very least, map reconnaissance can be performed. Ultimately, a computer run network using Dykstra algorithms can be used to simulate route reconnaissance to determine the shortest or quickest routes.
8. Displacement

This function is central to the integration of tactics and logistics. Displacement routes must be well planned and coordinated with the resupply plan. The movement times must be minimized in order to maximize availability time. Routes which are under air defense umbrellas may be longer but they reduce casualties. Displacements must be timed so as to avoid falling too far behind maneuver forces or to avoid getting overrun by the enemy. Additionally, displacements should be timed to minimize the amount of time a unit spends above the commander's vulnerability threshold. All of these tradeoffs should exist within the wargame as well as the actual movement of the units along the paths and nodes of the previously mentioned network.

9. Communications

Some sense of communicating orders and receiving reports must be contained within the game. The computer assisted portion of the game will provide this service. The players will be able to establish certain standard operating procedures (SOP) to control such things as the frequency of standard reports like the unit situation reports.

10. Combat Service Support (CSS)

This function is obviously critical to accomplishment of the wargame's mission. In order to give proper emphasis to the importance of this function, each of
the ammunition resupply trucks will be explicitly played. Of the various types of supplies, only ammunition will be played in the first iteration of the wargame. This is because the other types of supplies are normally played through actual consumption even in peacetime exercises. It is ammunition which has the most bulk and the largest impact on tactics.

This analysis of the wargame's mission, along with its implied tasks, provides a discussion of the wargame's intended purpose, its scope, and a brief description of the functions it must be able to perform.

C. GOALS OF THE WARGAME

The goals of the wargame are defined on two levels. The first concerns the goals of the wargame's design and the second concerns the goals of the players of the wargame.

The goals of the wargame's design should simply be to design the wargame so that each of the battalion's goals are not only played, but also their degree of accomplishment is measured. Specifically, availability, vulnerability, casualties, and logistics optimization should all be played in quantifiable terms so that they can be measured by the computer portion of the wargame. Once they are measured, a measure of effectiveness (MOE) can be computed. This MOE provides feedback to the player so that they can reassess
their decisions and perhaps improve their MOE the next time the wargame is played.

The goals of the players should therefore be the same as for actual operations: to maximize fire support provided to maneuver units by maximizing availability time, to minimize the amount of time spent above the commander's vulnerability threshold, to minimize the time lost to casualties, and to minimize the amount of time units spend either critically short or out of ammunition.

These parallel goals (between the wargame and the players) serve as the thread of continuity which ties the wargame together. The wargame should be designed to accomplish the wargame's system goals and all components of the system should contribute to the furtherance of the goals within the intent given by the wargame's mission. In this way, the players will be able to use the same decision criteria in playing the wargame as they would in wartime. Their objective is to maximize the measure of effectiveness (MOE) by seeking to accomplish the player's goals which are the same goals which are found in the field artillery battalion system.

The actual MOE used for this wargame, named the Field Artillery Battalion Command and Control (FABCAC) Effectiveness Index by the authors, is directly related to each one of the goals. The MOE is as follows:
MOE = "tube hours available" ratio - "truck hours lost to casualties" ratio - "tube hours above the vulnerability threshold" ratio - (.5 * "tube hours critically short of ammunition" ratio).

Each of the ratios in the MOE is in terms of actual hours over maximum possible hours. Tube hours lost due to casualties are not explicitly listed in the MOE because they are accounted for under availability time. Tube hours lost due to ammunition outage are also accounted for under availability time. By accounting for ammunition outage under availability time, the players are afforded the opportunity to minimize the effect of an ammunition zero balance by moving a unit since it cannot shoot anyway. In this way, the players can get the unit into a better position tactically and set its vulnerability level to zero while out of ammunition rather than during a period in which the unit could be shooting.

D. WARGAME ENVIRONMENT

The wargame simulates many of the more important aspects of the field artillery battalion system environment. First and foremost is the fact that the battalion exists in a hostile environment. This is reflected in the wargame by inducing attrition of howitzers and ammunition trucks using Lanchester-type equations. Attrition takes place both in positions and along displacement routes. Attrition rates are based upon force postures and the tactical situation.
Command and support relationships should be understood by the players. The wargame is consistent with actual doctrine in this respect.

The facts that all of the units exist on the battlefield, are separated by considerable distances, are in positions which provide varying degrees of cover and concealment, and must move around the battlefield are all important to the design of the wargame. It is anticipated that the computer generated network will allow these aspects of the environment to be simulated. Many of the nodes will represent positions which afford varying degrees of cover and concealment. The paths indicate the distances between nodes and are used to control the movement of units between nodes so that realistic travel times are generated based upon path capacities. Additionally, paths have attrition characteristics which will determine the amount of attrition incurred by a unit while on that path.

Finally, "friction" is an important element to portray in any military wargame. Units will not always move through a route exactly as scheduled. Enemy artillery attack will cause unscheduled moves. These kinds of problems are also found in the wargame in order to cause the players to be flexible and issue fragmentary orders to rectify the situation.

The approach for the actual physical environment of the wargame involves a computer program which is written for
execution on a personal computer. It is important to restrict the wargame to execution on a PC because that is all that most battalions have readily accessible. This wargame can be played by the O&I section, the logistics section, and the battalion commander in the battalion headquarters or the PC can be set up in the battalion tactical operations center (TOC) in the motor pool. In either case, situation maps and status boards will be necessary not only to keep up with the battle, but also to help evaluate the effectiveness of the section’s SOPs and information management procedures.

E. WARGAME RESOURCES

Other than the players themselves, personnel are not explicitly played as a part of this wargame. It is assumed that when equipment is lost, its personnel are also lost and vice versa.

The only equipment represented in the wargame are howitzers and ammunition trucks. These are the primary high density items of equipment found in a battalion. They are also the items of equipment which most significantly impact on the accomplishment of the wargame’s mission.

The only supply represented in this version of the wargame is ammunition. Ammunition, by far, represents the most bulk in resupply operations and is directly involved in the integration of tactics and logistics.
In order to effectively run the wargame, the following resources will be necessary:

1. Operations players, logistics players, and commander.
2. One, IBM compatible, personal computer.
3. Maneuver unit operations order, overlays, and maps.
4. O&I section and logistics section status boards and map boards.
5. Wargame computer software and user’s manual.

F. MANAGEMENT OF THE WARGAME

All of the management as defined for the field artillery battalion system will be handled within the human interaction portion of the wargame. The commander will provide direction and leadership to the staff and he will make final decisions. The staff (O&I and logistics) will prepare estimates and plans. They will also assist the commander in monitoring operations by interpreting reports and preparing and communicating orders and by assessing the situation to determine if the plan needs to be modified.

G. ARCHITECTURAL DEPICTIONS

Once again, an effort has been made to separate the architectural depictions into four categories which represent functional, spatial, informational and time relationships. The architectural depictions have been separated from the previous discussion because most of the depictions transcend any one aspect of a system and
therefore serve to tie together the previously mentioned ideas. Additionally, they reveal new aspects of the system which have not already been discussed.

1. **Functional**

"Functional architecture describes the technical structure of large systems." [ref. 7: p. 2.4] Figure 3.1 represents a decision taxonomy known as the "SHOR" paradigm [ref. 2: p. 626]. Within the context of this thesis, the "SHOR" paradigm is used to indicate, at a conceptual level, the boundary between the human portion of the wargame and the computer portion of the wargame. What is inside the dotted line is the human portion of the game and what is outside the dotted line is handled by the computer. An interpretation of the depiction indicates that the computer will provide some kind of trigger event which will provide the stimulus or data to the players (S). This will cause the players to attempt to interpret the data to determine what it means in relation to their mission accomplishment (H). They will then create alternative courses of action to counter the perceived impact of the data (O). Finally, they will take action by issuing an order (R). This order is executed by the computer and has some effect on the environment. The players monitor the environment and collect raw or preprocessed data and the cycle repeats itself. At any given time, multiple stimuli can be received by the players which can result in one or more responses.
THE SHOR MODEL

Figure 3.1 The SHOR Model
The entire process takes place continuously for the duration of the game.

Figure 3.2 is the computer architecture which will be used for the wargame. It has been divided into three major modules: the Pre-Processor, the Game, and the Post Processor. Each of these major modules has been divided into the lesser modules representing functions which are required to be performed to support the major module. Some of the more significant points which can be derived from this depiction are that the players will be able to input their own scenario if they do not want to use the one that will come with the game, the players will be able to input some of their own parameters which will represent their unit SOPs and commander’s guidance, and finally, the players will be able to save a game which is in progress and then get back to it later.

2. Spatial

Spatial architecture depicts the physical relationship of the elements in the system. Figure 3.3 depicts a basic level configuration for game’s set-up requirements. Figure 3.4 depicts the spatial relationship of the elements of the field artillery battalion within the wargame. In this figure, it is apparent that all of the elements are spatially related to each other through the use of the network architecture. Units are located at nodes and
Figure 3.2 Computer Architecture
Figure 3.3  Wargame Setup Requirements
Figure 3.4 Artillery Wargame Spacial Architecture
displace along paths. The legend contains a listing of the various characteristics of nodes and paths.

3. Informational

Informational architecture depicts the flow of information within the system. Figure 3.5 is very similar to Figure 2.4 except that only those elements of information which will be used in the wargame have been listed on the diagram. Additionally, in Figure 3.5, the dotted line separates the game's players from the computer portion of the wargame.

4. Time

The time-based architectural depiction for the wargame is the same as for the field artillery battalion system. In both cases, the process that the key people must use to make decisions remains the same. Therefore, Figure 2.5 applies equally well to the wargame.

H. SUMMARY

The basic conceptual approach taken for this wargame has been to analyze a field artillery battalion from a systems point of view. Then, using the knowledge gained from this analysis, lay out the conceptual framework for a wargame which emulates the pertinent aspects of the field artillery battalion. Once again, the systems approach is very useful in laying out this framework because it requires that every
ARTILLERY WARGAME
INFORMATION ARCHITECTURE

Figure 3.5 Artillery Wargame Information Architecture
facet of the system be considered under the categories of mission, goals, environment, resources, and management.

The wargame attempts to capture this framework in a form which provides a learning environment for those tasked with the command and control of a field artillery battalion. The wargame is only computer assisted since the essential element of any tactical command and control system is the human decision maker. The computer portion of the wargame only provides relevant information to the decision maker and then executes his decisions and keeps track of the game's statistics. At the end of the game, an MOE is calculated which provides an assessment of the player's performance. This forces the player to plan ahead and consider all the relevant concepts in order to maximize howitzer availability time, minimize casualties, minimize vulnerability time and optimize ammunition resupply. The intent of the wargame is to provide an environment in which officers can learn to consider the factors which are critical to the integration of tactics and logistics.

The computer program itself is complex. It utilizes a network architecture to facilitate the movement of firing batteries and ammunition convoys and it uses Lanchester attrition equations to decrement forces. Among other things, the program simulates firing, consumption of ammunition, movement of units, ammunition resupply, and changes in the tactical situation. Periodic reports as well
as emergency messages and warning reports are output to the
decision maker. The decision maker has the ability to issue
commands to the units. Among the commands are movement
orders, firing rate orders, ammunition resupply orders and
requests for situation reports from the units.

Finally, all this must be done in a format which is
usable at the battalion level. This means that it will be
executable on a personal computer, it will be well
documented, and it will enable the players to use their
normal unit / section SOPs.
IV. WARGAME DESIGN

A. INTRODUCTION

The purpose of this Chapter is to supplement the documented source code which can be found in the Appendix. A description of the code's structure and organization can be found in the documented source code. In this Chapter, a description of the overall design used in the coding of the computer portion of the wargame will be given.

Turbo Pascal version 5.0 and Turbo Pascal Database Toolbox version 4.0 were used to code the wargame. Turbo Pascal was used is because Turbo Pascal is one of the most popular programming languages on the market. By using Turbo Pascal, there is a reasonable expectation that users will be able to modify their own source code.

In order to implement the wargame as described in Chapter III, a "Time Step - Event Driven Hybrid" design was used. An "Event Driven" design was needed to enable the players to issue orders for future operations. A "Time Step" design was used to perform the routine functions which constantly occur over time in an artillery battalion. The hybrid design will become more apparent later in this Chapter.

Finally, a great deal of the design considerations used for the wargame revolve around the desire to make the game as "user friendly" as possible. In order to achieve this
objective, no computer commands are used in the wargame. Everything is menu driven. All data entry fields are protected so that only the correct type of data can be entered. The terminology used by the game is as close to actual military terminology as possible.

B. OVERALL WARGAME DESIGN

The wargame's overall design can be described by referring to Figure 4.1. Note that upon loading the game there are three choices: "Play New Game", "Play Old Game", or "Quit." If "Quit" is chosen, the player is returned immediately to MS-DOS. If "Play Old Game" is chosen, the old game's files are loaded and the program goes straight to the Game Play Module. Finally, if "Play New Game" is chosen, the Pre-Processor Module is entered. The Pre-Processor is the portion of the computer program which allows the player to set up or initialize the game with such data as the battalion's configuration, the unit movement network, the commander's guidance, the game's scenario and the game's parameters. When the player is finished with the Pre-Processor Module, he enters the Game Play Module.

From within the Game Play Module, the entire game is played. The design of the game itself will be discussed later in this Chapter. From the Game Play Module, the player can quit the game at any time. Upon deciding to quit, the player has two options: either to quit with the
Figure 4.2  Game Flow Chart
intent to continue playing the game later or to permanently quit the game. When "Quit and Return" is selected, the game's files are saved to disk. In both cases, the program then enters the Post-Processor Module.

In the Post-Processor Module, the game's statistics are tabulated and the Field Artillery Battalion Command and Control Effectiveness Index is computed. After this information is printed, the program returns the player to MS-DOS.

C. RECORDS

The basic data structure used in the wargame is the record. The following records are used by this version of the wargame.

1. Scenario Record
2. Commander's Guidance Record
3. Game Parameters Record
4. Field Trains Record
5. Fire Unit Record
6. Ammunition Truck Record
7. Events List Record
8. Node Record
9. Path Record

The fields contained in each record can be found in the global declaration section of the source code. The first four types of records are all single records. The fire unit records and the ammunition truck records are maintained in
an array of records. Finally, the last three types of records are all stored in their own B+ lists in disk files created by the Turbo Pascal Toolbox. The events list records are stored in increasing order according to the event's date time group. The nodes and paths are each stored in their respective lists according to the node and path name.

The reason that the fire unit records and the ammunition truck records are stored in arrays is because there are only a finite number of those records and because every record must be accessed every time step. On the other hand, the event list, node, and path records are stored in database files because there are potentially an unlimited number of these records and because only selected records will be accessed in any given time step.

D. GAME PLAY DESIGN

The Game Play Module was designed in accordance with the flow chart depicted in Figure 4.2. Note that in this top level flow chart for the Game Play Module there is only one decision point. This was deliberately designed in order to focus all aspects of the game at one point. This point is referred to throughout the rest of the thesis as the "hub of the wargame." From this hub there are three possibilities: the Time Step Module, the Issue Commands Module, and the Change Game Initialization Module.
Figure 4.1 First Order Flow Chart
If the "Change Game Initialization" option is chosen, the program takes the player to many of the same procedures that were used in the Pre-Processor Module. The player is given the opportunity to change commander's guidance, add nodes and paths, and change some of the game's parameters.

If the "Issue Commands" Module is chosen, the player is given the option of issuing one of several commands. The list of possible commands follows:

1. Convoy Ammunition Trucks
2. Dissolve Ammunition Truck Convoy
3. Move a Unit
4. Request a Unit Situation Report
5. Change a Unit's Firing Rate
6. Assign Ammunition Resupply Mission
7. Assign Ammunition Pickup Mission
8. Issue a Fire Order
9. Cancel a Command

In most cases, the result of a command is to add or delete one or more events list records. In some cases, it involves direct modification of ammunition truck records or fire unit records.

If the time step is chosen, the program will increment the game time and then search the events list to retrieve any records with an execute time between the last time step's game time and the current game time. As each record is retrieved, it is executed based upon the record's key.
field. The key field contains the "type action" which took place. This "type action" is what determines which procedure is called. After all applicable events are executed, the program enters the Field Trains Processing Module, followed by the Ammunition Truck Processing Module, then the Fire Unit Processing Module, and finally the Generate Messages Module.

In the Field Trains Processing Module the vulnerability level is determined, then the program checks to see if the unit receives an enemy artillery attack, and finally, casualties are computed. In each of the different type of unit modules, the vulnerability level is determined and then casualties are assessed based on the linear law form of the Lanchester attrition equations. More will be said about the assessment of casualties later in this Chapter.

Additional functions which take place in the Fire Unit Processing Module include the firing of ammunition by each fire unit, the determination of each unit’s ammunition count / status, and the update of such fire unit statistics as availability time and ammunition critically low time.

In the Ammunition Truck Module, the program conducts the actual resupply operations, checks for sufficient crew rest to carry on with the mission, assesses casualties, and increments the truck’s statistic. The only statistic which is tracked is the truck’s casualty time.
The last module of the time step is the Generate Messages Module. There are two general categories of messages, those which are sent to the players by the battalion's subordinate units and those which are sent by other elements. The former category of messages is generated by checking for various flags in each subordinate unit's records. The later type of message is generated at random times throughout game. Examples of this type of random message include such messages as the "Bridge Destroyed" message and the "Road Mined" message.

E. PROGRAM ILLUSTRATION

In order to illustrate how all the different modules work together, an ammunition resupply operation will be described. It is important to note that an operation of this type may be only one of many operations taking place concurrently in the game.

The operation which will be used for the illustration involves ordering a convoy of five trucks to move from point "A" to point "B" to deliver their loads of ammunition. Multiple commands must be used to issue this order. First, if not already organized into a convoy, the "Convoy Ammunition Trucks" command must be issued. In order for this command to be executed, all trucks must be in the same location. Next, the "Assign Ammunition Resupply Mission" command must be issued. This command modifies all the truck records in the convoy to reflect the fact that a mission has
been received, and to reflect the fire unit to be resupplied and the node in which the resupply is to take place. All trucks in the convoy must have full loads of ammunition on board in order for this command to be executed. Finally, a "Move Unit" command must be issued. In this command, either a depart or a occupy time is specified and a route is specified in terms of nodes and paths.

When the "Move Unit" command is entered, a procedure is called which builds an itinerary for the unit. It takes either the depart time or the occupy time and works either forward or backward as appropriate to determine the itinerary. The time required to traverse each path is determined based upon the length of the path, whether it is day or night, the road conditions, and the type of convoy.

Using this information, event list records are created for the time that the unit departs its current location, the time that a unit moves through each node in the route, and the time that the unit occupies its new location. During each subsequent time step, the events list is checked. For each event relating to this move, the convoy's location is changed as well as other fields in the record. Also during each time step, the trucks in the convoy have casualties assessed based upon the vulnerability level of the path they are traversing and whether it is day or night.

Once the convoy arrives at its destination, each truck in the convoy is taken out of a moving status when the
occupation event is processed. In all subsequent time steps, until the resupply operation takes place, the program will check to determine if both the convoy and the unit to be resupplied are in the same location. If they are, the resupply operation will take place. After the resupply operation has taken place, the fire unit’s ammunition count is incremented and each truck in the convoy’s ammunition count is decremented. At the end of the time step a message is generated from the convoy to the battalion S4 notifying him that the mission has been accomplished and requesting further orders.

F. CASUALTIES

For the purposes of this wargame, it has been assumed that the artillery units would not receive any direct fire from enemy units. The only types of enemy fires in this wargame are from enemy air attack and from enemy artillery attack. Both of these types of attacks are produced by area fire weapons. Therefore, the Lanchester linear law differential model was used to assess casualties. Specifically, the following form was used:

\[
\frac{dx}{dt} = -ay
\]

Where "a" is the attrition coefficient, "x" is the number of friendly elements being attrited, and "y" is the number of firing elements.
For this wargame casualties are calculated based on three different possible unit postures: unit in a position, unit in a position and receiving a deliberate artillery attack, and unit moving. For each posture there are four different attrition coefficients: friendly cannons attacked by enemy artillery, friendly cannons attacked by enemy bombs, friendly trucks attacked by enemy artillery, and friendly trucks attacked by enemy bombs. The underlying unit of time for these coefficients is one minute.

The number of friendly elements being attrited, "x", is the percent of each truck which is remaining for ammunition trucks. For firing units it is the number of firing sections in operating condition.

The number of enemy firing elements, "y", is considered in two parts: enemy air bombs and enemy artillery rounds. This variable can be considered to be related to the intensity of the attack. For this wargame, the intensity of the attack varies according to several factors. Some of these factors are listed below:

1. Day or night
2. Rural or urban position
3. High Medium or low cover and concealment
4. Acceptable, high, or critical vulnerability level
5. Maneuver mission offense or defense

For each type of enemy weapon, air bomb or artillery round, the number of attacking elements is determined by summing
the number of bombs or rounds contributed by each factor. For example, if a fire unit is in an urban position, the time is later than end-evening-nautical-twilight (EENT), the position has good cover and concealment, the unit's vulnerability level is acceptable, and the supported maneuver unit's mission is offense then the value of "y" is determined by summing the number of bombs or the number of artillery rounds for those particular factors which are applicable to the unit's situation.

Next, the casualties assessed against the friendly truck or fire unit due to each type of enemy weapons system, air bomb or artillery round, are calculated and then summed. Once the casualties for one minute are determined, they are multiplied by the number of minutes in a time step and then assessed by subtracting the determined amount of casualties from the truck's effective percent figure or from the number of firing sections in operating condition for fire units.

By computing casualties in this manner, one procedure is used to determine casualties for any given situation by passing the appropriate parameters in the procedure call. The parameters are the type unit, the unit's posture, and factors which are applicable to the situation at hand.
V. PLAYER'S MANUAL

A. INTRODUCTION

This chapter is intended to provide a stand alone player’s manual for the play of the wargame. For information concerning the technical aspects of the code, refer to Chapter IV or to the documented source code itself. In this chapter, the mechanics of actual game play will be discussed.

The wargame can be thought of as consisting of two parts, the computer assisted part and the manual part. In the manual portion, players should attempt to operate as closely as possible to the way they normally operate during combat or simulated combat conditions. The computer assisted portion of the game involves a computer program which provides the dynamic information which the players use to make command and control decisions. The computer assisted portion also keeps track of statistics and calculates a measure of effectiveness which can be used to assess player performance.

The wargame can be played at any level of intensity. That is, the players can play the manual portion of the game at a full scale with written orders, staff estimates, and detailed planning or they can play it relatively casually by just using "judgement" or "best guesses" to make decisions.

65
In either case, the computer assisted portion of the game remains the same, it simply takes the human input and processes it. The point is that the game can be played as a part of a full battalion CPX or during weekly officer professional development time. This is possible because the wargame is designed to be played at the player’s pace. The pace is determined by the player by requiring him to physically initiate each time step.

In order to make the wargame easy to learn and remember, the wargame was designed to be completely menu driven. There are no commands to remember.

B. MEASURE OF EFFECTIVENESS (MOE)

It is important to discuss the wargame’s measure of effectiveness up front in the player’s manual because it tells a lot about what the game’s objectives are and what the player’s objectives should be. While playing this game, the player should always keep in mind the fact that the mission of the wargame is to train officers in the integration of tactics and logistics as it relates to the command and control of a field artillery battalion. As such, the game is oriented toward the integration of tactics and logistics and may not do justice to other important aspects of a field artillery battalion.

The player’s objectives should be to play the game by taking the same actions they would take in a real situation while trying to maximize the game’s MOE. The MOE is
calculated based upon statistics which are compiled throughout game play. The intent of the MOE is to reinforce favorable statistics and to penalize unfavorable statistics. In this way, players can judge how effective they were at the command and control of the field artillery battalion.

The statistics which are tracked in the wargame mirror the four goals of a field artillery battalion as discussed in Chapter II. The actual MOE, called the Field Artillery Battalion Command and Control Effectiveness Index, is directly related to each one of the goals. The MOE is as follows:

$$\text{MOE} = \frac{\text{tube hours available}}{\text{tube hours lost to casualties}} - \frac{\text{tube hours above the vulnerability threshold}}{\text{tube hours lost to casualties}} - \frac{\text{tube hours critically short of ammunition}}{\text{tube hours available}}.$$ 

Tube hours lost due to casualties are not explicitly listed in the MOE because they are accounted for under availability time. Tube hours lost due to ammunition outage are also accounted for under availability time. By accounting for ammunition outage under availability time, the players are afforded the opportunity to minimize the effect of an ammunition zero balance by moving a unit since it can’t shoot anyway. In this way, the players can get the unit into a better position tactically and set its vulnerability level back to zero while out of ammunition rather than during a period in which the unit could be shooting.
C. GETTING STARTED

To start the computer assisted portion of the wargame, the players must first ensure the printer is turned on and is on-line. At the "A:" prompt, type **WARGAME** and press "return." This will take you to the Main Menu. Throughout the wargame, the "arrow" keys are used to move the cursor to the various choices, the "return" key is used to make a selection and the "F1" key is used to get help. Any data fields which require a choice to be made between such entries as "high", "medium", or "low" can be entered by just typing the first letter of the word, e.g., "h", "m", or "l". At the main menu the player has three options; start a new game from the beginning, continue an old game from the point where the game was previously quit, or simply to quit the game and return to the MS-DOS "A:" prompt.

Selecting "Continue an Old Game" will take the player directly to the game play screen and will pick up with the one and only old game which is on file on that particular disk. Selecting "Start a New Game" will require the player to initialize the game. This can be done by loading a scenario file. The "Enter Scenario File Name" screen allows the player to do this. Refer to Figure 5.1 at the end of the Chapter. When the screen first is displayed, the cursor is after the "scn" on the directory line. The player has two options. He can hit "return" to get a directory listing of all the scenario files on the disk or he can press the
"escape" key to build a new scenario file. If the "escape" key is used, the program will require the player to enter a scenario name. A valid scenario file name is "*.SCN." If the player chooses the directory listing, then he must place the cursor over the file name desired and press "return." Either case will lead to the Game Setup Menu.

D. GAME SETUP MENU

The purpose of this menu is to allow the players to start the game or view, change, or print the game scenario/network, the game parameters, the commanders guidance, and the battalion configuration/status. All but the "Play Game" option will be discussed in this section. The "Play Game" option will be discussed in Section E of this chapter.

It is strongly recommended that players print all of the game initialization data before beginning the game. This serves two purposes. First, it forces the player to review the data to ensure it is correct. Secondly, it gives the players a hard copy of the data that can be used throughout the game as a reference. All printing is done by pressing the "F4" key. This prints the currently displayed screen.

Throughout the view and change options, use the arrow keys to move between fields, use "page up" and "page down" to move between pages where applicable, and use the "escape" key when finished with an option.
1. View or Change Scenario / Network

This option takes the players to another menu which allows them to view, change, or print the administrative information contained in the scenario file, the network node data, and the network path data. It also allows them to use the network utility to test the network.

The term "network" as used here refers to the unit movement network. Unfortunately, all unit movement in this game is represented by moving along this network. This will require the player to translate from grid coordinates and routes on the map to nodes and paths in the unit movement network.

In this network, nodes represent positions, or potential positions. Paths represent a route between two nodes. The nodes have a specific grid location on the map whereas the paths provide connectivity between two nodes. There may be two or more paths between the same two nodes. The conventional depiction of a network shows the paths between nodes as straight lines. For this wargame, it is recommended that an overlay be developed which shows all of the nodes as circles over their grid locations and all of the paths as route traces of the routes represented by each path. Each node and path will be labeled with a unique name. (Nodes are labeled with up to three numbers and paths with up to three letters.) In this way, the players can do their normal planning. When they give the movement order to
the computer assisted portion of the wargame, they use the overlay to dictate the route. (A future version of this game should just take the start and end nodes and determine the optimal route.)

Under the node data and path data options, the bulk of the network can be setup before the game. However, it is still possible to add nodes and paths during game play. The importance of setting up a good network cannot be over emphasized. The larger and more comprehensive the network, the more flexible and more realistic the game play will be for the players. The entire game is structured around the movement network. Units occupy nodes and move along paths. Point distribution of ammunition must also take place in a node.

The computer assisted portion of the game is interested in more than just location and length information for each node and each path. There are many other elements of information which are necessary to describe the nodes and paths. These will be covered in more detail in paragraphs b) and c) in this section.

a. Scenario Information (Figure 5.2)

This option allows the players to view, change, or print the administrative information contained in the scenario file. This screen contains the operations order number, the date of operations order, the map sheets used in the scenario, the game start time, and finally an
administrative note to be used at the discretion of the scenario builder.

b. Path Data (Figure 5.3)

Most of the fields in the path data screen are self explanatory. However, a few will require some explanation. A path in this game can have no more than one bridge. The player will have to pick a bridge if there is actually more than one bridge on the map. Road conditions and path vulnerability each have three levels of quality. It is up to the players to make this assessment in accordance with the relative conditions in the game's area of operations. To get the first data screen, press "F5."

c. Node Data (Figure 5.4)

The node data screen is also fairly self explanatory, however, a few items require some discussion. A given node must have at least one but no more than six paths associated with it. A node can have an ammunition count independent of any fire units or ammunition trucks. This gives the players the ability to preposition ammunition at a node for eventual transfer to a fire unit or ammunition truck. The type position and cover and concealment fields are like the path vulnerability and road condition fields in that the entry is at the discretion of the players but should be based upon the relative conditions in the area of operations. All of these fields are important to the game.
because they are some of the previously mentioned factors which help to determine the casualty rates.

d. **Network Utility**

This option has not yet been implemented. It will eventually allow the player to test the network by tracing routes through the network and determining route distances.

2. **View or Change Game Parameters (Figure 5.5)**

This option allows players to view or change the game parameters. The game parameters are generally expected values of such variables as convoy speeds. These expected values can be set by the players to reflect the average speeds based on a specific area of operations or opposing force. For example, an area with a good road network will have a higher expected value for the convoy speed. The actual values used by the game will be based on these expected values but will vary according to many factors. Examples of some of these factors are the unit’s mission, the road conditions on the specific path, the intensity of conflict, etc.

3. **View or Change Commander’s Guidance (Figure 5.6)**

This option allows the player to view or change elements of commander’s guidance. The commander’s guidance data consists of items which could be part of a unit’s standard operating procedure (SOP), part of a specific operations order, or verbal guidance given by a battalion or
division artillery commander for a specific operation. The commander’s guidance can also be changed while playing the game.

4. View or Change the Battalion Configuration / Status

This option allows the player to view or change data concerning the battalion’s field trains, fire units and ammunition trucks. The data concerning these elements is the data that will be used to start the game.

Upon selecting this option, another menu is displayed. The first choice allows the player to view or change the trains location. The second option allows the players to view or change the number of fire units, and the number of ammunition trucks in the battalion at the beginning of the game. The third choice allows the player to view or change the starting firing unit data. And the last choice allows the player to view or change the starting ammunition truck data.

a. Location of Trains

This screen contains only the field trains location. Note that the correct entry for all location fields in this game are in terms of the unit’s position node name.

b. Number of Fire Units / Trucks (Figure 5.7)

Whatever numbers are entered for the number of fire units and the number of ammunition trucks determines the number of screens that are created for the next two
options. The maximum number of fire units in this game is six and the maximum number of ammunition trucks is twenty-four. If there are three fire units currently on disk and six is entered for the number of fire units, then the third fire unit's data will be duplicated three more times for the additional three fire units. The next option can be used to edit the new fire unit records.

c. Firing Unit Data (Figure 5.8)

Use the "page-up" and "page-down" key to move between the various pages of fire unit data. Most of the fields on these screens are self explanatory. However, a few require additional explanation.

The location fields indicate the locations of the units at the beginning of the game. These locations are in terms of nodes. From a game play perspective, these positions can be pre-hostility assembly areas or they can be initial firing positions. At the beginning of the game, the player will be queried at the start of each time step as to whether or not hostilities have commenced. If the answer is no, the game continues but no casualties are assessed and no rounds are fired. If the answer is yes, the game continues with firing and casualties and the players will no longer be queried about the beginning of hostilities. This procedure gives the players the ability to exercise a pre-hostility deployment plan and tactically position their fire units and
their ammunition trucks prior to the commencement of hostilities.

The maximum rounds capacity per firing section field refers to the number of rounds the particular weapon system / organic ammunition carrier can carry combat loaded. The number of rounds on hand per fire unit can exceed the unit's total capacity while in a firing position. However, when the fire unit displaces, it can only move with its maximum total capacity. The excess rounds will be left as prepositioned ammunition on that node. Separate arrangements must be made with battalion ammunition trucks to transport that ammunition if necessary.

d. Ammo Truck Data (Figure 5.9)
As with the fire unit data, use the "page-up" and "page-down" keys to move between screens. All of the fields should be self explanatory.

E. GAME PLAY
After completing the initialization process, the player should select the game play option. This will lead to the game play control screen (Figure 5.10) which is the hub of the wargame. From this screen the players can initiate time steps, issue commands, change parameters, utilize the network utility, and they can end the game play by selecting the quit option. The game time will always be displayed on any screen which is generated out of the game play control screen.
In order to play the game, the following players are required as a minimum: A battalion commander, a battalion O&I section, and a battalion S-4 and/or Service Battery Commander. These players are required in order to integrate tactical and logistical planning and execution.

The game is actually played by initiating a time step, viewing and/or printing any messages which may be generated during the time step, and then issuing any commands which may be necessary for the battalion to execute its plans. The players themselves should act out their own roles as if the wargame were actually a real situation. However, rather than sending or receiving information/orders using a radio, the players will receive information from the computer and will send orders to the units represented by the computer.

The players should conduct all planning in accordance with their own unit standard operating procedures and Army doctrine. For the computer assisted portion of the game, special emphasis should be given to logistics plans since the computer will require detailed orders for ammunition resupply. Fire plans should also be made either manually or using TACFIRE. Finally, plans should be made well in advance for future fire unit moves so that routes can be planned thereby facilitating timely execution.
1. **Time Step**

This option will process all events which take place from the current time to the new current time. The difference between these times equates to the length of a time step. The time step size is set by the players under the game parameter option during game setup. A size of 30 minutes is recommended.

There are many functions which take place during the time step. The fire units shoot at some rate which is a function of the battalion's CSR but can not exceed the weapon system's sustained rate of fire. Resupply transactions take place between ammunition trucks and fire units in accordance with their orders. Ammunition trucks return from the ammunition transfer point with new truck loads of ammunition but the total ammunition drawn in a day can not exceed the battalion's CSR. Units / trucks move around the battlefield in accordance with their orders. Units may receive incoming artillery and must request permission for an emergency displacement. And finally, units / trucks may receive casualties where the degree of casualties is based upon numerous factors such as the type position, the position's cover and concealment, and the unit's vulnerability factor.

Casualties are determined each time step whether the units are in a position or are on the move. Casualties are assessed as fractional parts of firing sections and
ammunition trucks rather than whole sections and trucks. This is a result of the fact that Lanchesterian attrition was used. Therefore, casualties are determined as an expected value over time rather than discrete amounts. Due to this fact, it is possible to have less than a whole ammunition truck and less than a whole number of firing sections in a fire unit. In turn, all quantities which are related to these systems are calculated based on the effective percent of the system. For example, if a particular ammunition truck is at 74 effective percent, then it can only haul 74 percent of its full ammunition capacity.

During the time step, the computer not only executes previously issued commands, but also generates messages for the players to review and, if necessary, take some action. A discussion of each message follows:

a. Incoming Artillery

This message notifies the battalion staff that the named unit is receiving incoming and that they request permission for an emergency displacement. It requires the players to make an immediate response of either "y" or "n." If "y" is entered, the unit will displace to its alternate position within the same node. It will be in a moving status for approximately 30 minutes. Upon occupation, its vulnerability level will be set back to an acceptable level. If "n" is selected, the unit will stay in position and ride.
the attack out. Casualties will be higher and its vulnerability level will continue to increase.

b. Unit Situation Reports

These messages will be displayed on a periodic basis in accordance with the battalion's standard operating procedure. The situation report frequency can be set using the "commander's guidance" option under the "Change Parameters" option of the Game Play Menu. Use the "page-up" and "page-down" keys to move from one unit situation report to the next. All fire units and the field trains will be displayed.

c. Bridge Out

This message will appear randomly. It notifies the players that a bridge on a certain path is out. It is up to the players to avoid the path once this message is received. If the players send a unit down a path which has a bridge out, then the time the unit spends on the path will be greatly increased.

d. Minefield

This message will appear randomly. It notifies the players that a minefield has been placed on a certain path. It is up to the players to avoid the path once this message is received. If the players send a unit down a path which has a minefield, then the time the unit spends on the path will be greatly increased and the casualties will be increased.
e. Vulnerability High / Critical

This message notifies the players that the vulnerability threshold for the named unit has become high or critical. To warrant a rating of high, a fire unit must exceed the commander’s guidance for either the number of rounds fired out of a position or the amount of time spent in a position. The rating becomes critical when both items of the commander’s guidance has been exceeded. For the field trains, the rating is high if too much time is spent in the position. And if two times the commander’s guidance for time in position is exceeded, the field trains receives a vulnerability rating of critical. In either case, the expected value for the degree of casualties increases as the vulnerability rating increases.

f. Ammunition Low / Critical / Out

This message notifies the players, as a real fire unit would, when the named fire unit’s ammunition levels decreases below certain thresholds. If the ammunition count is below 35 percent of the unit’s maximum capacity, then the ammunition status is "low." If the ammunition count is below 10 percent of the unit’s maximum capacity, then the status is "critical." And finally, if the ammunition count is 0, then the ammunition status is "out."

There is no penalty for an ammunition status of "low." It simply serves as a warning to the S4 to begin
planning for ammunition resupply operations to that unit. If the status is "critical", then the unit is not considered fully available. The amount of time a unit spends critically short of ammunition is incremented and, at the end of the game, a portion of the critically short time is subtracted from the availability time. Finally, if the unit is "out" of ammunition, it is placed in a cold status and is therefore not available to support the maneuver forces. The "Change Rate of Fire" command can be used to tell a firing unit to decrease or increase its rate of fire.

g. Resupply / Pick-up Complete, Request Orders

This message is generated when an ammunition truck has completed an ammunition resupply or pickup mission and needs further guidance. The players then must issue the appropriate commands to instruct the truck where to go and what to do. In most cases, since the truck can only go to the ammunition transfer point from the field trains location, the players will issue an order to get the truck back to the field trains. Another option would be to instruct the truck to go to a specific node to pick up prepositioned ammunition.

This approach was taken because most ammunition trucks / convoys do not have organic radios. In most cases they would call the field trains, utilizing the resupplied unit's radio, to give a situation report after accomplishing their resupply mission.
h. Return from Ammunition Transfer Point, Field Trains Gone, Request Orders

This message is generated when an ammunition truck returns to what was the field trains location and finds that the field trains is no longer there. The player's reaction should be to issue orders to the truck either to get to the field trains or to go somewhere else to deliver the ammunition.

i. Crew Rest Warning

This message is generated when an ammunition truck is given a movement order and the truck's crew has not had the amount of rest dictated by the commander's guidance in the last 24 hours. The truck will still accept the orders, but the casualty rate will be a little higher. If the crew has not had the amount of rest dictated by the commander's guidance in the last 48 hours, then the truck will not be able to accept the orders. This will force the battalion's logistics planners to use all of the trucks equally and to consider crew rest in their planning.

j. Front Line Trace Change

This message will be generated on a random basis. When the maneuver forces are in the offense, the front line trace will move some specified distance usually towards the enemy in the direction of the attack. When the maneuver forces are defending against an enemy attack, the front line trace will move some specified distance usually toward the friendly forces in the direction of the enemy.
attack. The player’s actions upon receipt of this message should be to redraw the front line trace on their maps and then check their firing unit’s ranges to determine if they need to be moved.

2. Issue Commands

This option is chosen to give orders to any of the game’s entities, i.e., firing units and / or ammunition trucks. Once chosen, the player is taken to another menu which lists each of the various types of commands. By selecting a command description from this menu, the player will be taken to the command screen. Most of the commands have a unique command number. It is recommended that the "F4" key be used to print the command screen so that the players can keep track of the commands given and their associated command number. The command number is needed in order to cancel a specific command.

a. Convoy Ammunition Trucks (Figure 5.11)

This command enables the players to organize the ammunition trucks into convoys. The convoy name must be unique. Up to 24 trucks can be placed in a convoy but a given truck can only be associated with one convoy. Furthermore, all trucks named in the command must be at the same location when the command is given. If the desired trucks are not all at the same location, then the "move" command must be used to get them all to the same place.
Once a truck is assigned to a convoy, it can only receive orders as a part of the convoy. If one of the trucks in the convoy can not accept a convoy order due to a critical lack of crew rest, then the truck will automatically be taken out of the convoy and will not execute the order.

b. Remove Ammunition Truck Convoy (Figure 5.12)

This command enables the players to break-up the named convoy. All of the trucks in the convoy will be disassociated from the convoy and will once again be able to receive orders as individual trucks.

c. Move a Unit (Figure 5.13a and 5.13b)

This command enables the players to order units to move around the battlefield. The players should first plan the move on a map of the battlefield. Once they determine where they want the unit to move, they should refer to the unit movement network overlay to determine if the appropriate nodes and paths exist to make the move. If they do not exist, the players should use the "change parameters" option to add the needed nodes and paths. Once this is completed or if the nodes and paths already existed, then this command screen can be used. All the fields on these screens should be self explanatory except the "node to resupply" field. If the unit making the move is a firing unit or ammo truck/convoy and it is supposed to pick up or deliver ammunition along the way, then the players should
enter the node where the ammunition resupply is to take place. This will cause the fire unit to stop at that node to pick up ammunition. If the ammunition resupply trucks are not there, then the ammunition resupply will not take place and the fire unit will continue on its way after one time step.

d. Request Situation Report

This command is used by the players to get an immediate situation report. The output of this command will be in the same format as the unit situation report which is generated on a periodic basis during the game. The situation reports for all units will be displayed.

e. Change Firing Rate (Figure 5.14)

This command is used to speed-up or slow-down the named fire unit’s rate of fire. The number entered for the firing rate is a percent of the battalion’s CSR. If the number exceeds 100, then the firing rate will be such that the unit, if in a firing status all day, will expend more than its "CSR worth" of ammunition. On the other hand, if the CSR is less than 100, then less than the "CSR worth" of ammunition will be expended. This command is intended to be used to manage the unit’s ammunition expenditure. One of the statistics reported at the end of the game is the amount of ammunition the battalion has on hand in excess of the battalion’s CSR. Since the CSR should never be higher than what the battalion requested as the required supply rate
(RSR), this statistic should be minimized. Therefore, the players should use this command both to ensure the fire units do not run out of ammunition and to ensure that too much ammunition is not on-hand at the end of the game.

If the firing rate entered is less than 50 percent of the battalion's CSR, then the unit will be considered less than 100 percent available. The percentage of time considered available will be the same percentage as the firing rate.

f. Ammunition Resupply Mission (Figure 5.15)

This command is used to assign a resupply mission to an ammunition truck or convoy. Legal entries for the "Unit to Resupply" field include any of the fire unit names and the word "prepo." By entering preposition, the players are telling the trucks to deliver the ammunition to a node where the ammunition will be unloaded. The players can then use the next command to tell a fire unit to pick up the ammunition.

For any resupply mission to actually take place, the trucks must be full and located at the same node as the fire unit. If a preposition mission, then the truck must be at the node specified in the resupply command. In order to get the truck and the fire units into the same location, one or more move command must be used. Therefore, to cause a resupply mission to be executed, the players must issue at least two commands, a resupply mission command and a move
command to the truck / convoy or to the fire unit or to both the fire unit and the truck / convoy.

It is important to note that since the wargame uses Lanchesterian attrition, the trucks are attrited by fractions of a truck. Therefore, as the game progresses, each truck will have a different effective strength. Since a truck can only carry its "effective strength" worth of a full truck’s hauling capacity, less rounds than full capacity of a truck will actually be delivered to the fire unit or node. This will require the players to keep track of each truck’s hauling capacity. This approach may not be 100 percent realistic but it does account for the expected value of casualties over time.

g. Ammunition Pickup Mission

Selection of this command will take the players to another menu. This menu gives them two options, "Fire Units" or "Ammo Trucks".

If "Fire Units" is chosen, the command screen (Figure 5.16) is used to tell a fire unit to go to a node to pick-up prepositioned ammunition. Like the resupply command, this command will require the players to give a move command to the fire unit if it is not already in the appropriate node.

If "Ammo Trucks" is chosen, the command screen (Figure 5.17) is used to tell an ammunition truck or convoy to go to the ammunition transfer point (ATP) to pick-up
ammunition. The trucks must be in the field trains location to receive this command. This constraint was imposed because it was assumed that the trucks would have to at least pass through the field trains on the way to the ATP to get paperwork, and / or fuel, food, maintenance, and rest.

The amount of time the trucks take to go to the ATP is randomly chosen based on a normal distribution with a mean of the "ATP turn-around time" as specified under the game parameters. It is important to update the ATP turn-around time whenever the field trains moves or the ATP moves. Unlike the resupply command and the fire unit pickup command, a move command is not necessary with this command.

The battalion can only pick-up its "CSR worth" of ammunition during any given day. Even if the day's allotment of ammunition has already been picked-up from the ATP, the wargame will allow the players to send trucks to the ATP. However, the trucks will return empty. The point is that it is up to the players to manage both the pick-up and delivery of ammunition.

h. Issue Fire Order (Figure 5.18)

This command enables the players to issue battalion level fire orders. It can be used to direct the fire units to shoot battalion level targets of opportunity or planned fires. Planned fires can be planned either manually or using TACFIRE to fulfil the requirements of the fire support annex of the maneuver unit's operations order.
Once the fire plan is finished, it can be sent to the fire units using this command screen. All that is necessary is the unit name, time to fire, and the number of volleys.

The intent of this command is to ensure that the S3 players are able to perform all of their responsibilities while trying to integrate operations and logistics in the command and control of the battalion. They must be careful not to shoot so much ammunition that the fire unit's rate of fire must be reduced to too low a level to be considered 100 percent available. On the other hand, they must conduct normal fire planning in support of the maneuver forces.

1. Cancel Command (Figure 5.19)

This command enables the players to delete the following commands: "Move a Unit", "Ammo Resupply Mission", "Ammo Pickup Mission", and "Issue a Fire Order." Each of these command screens has a "command number" field which contains a computer generated number. It is this number which is entered into the "Cancel Command" screen in order to cancel a specific command. For all but the "move" command, the command must not have been executed in order for the "cancel" command to have any effect. In the case of the "move" command, if the move has already begun but is not yet completed, the "cancel" command will cause the unit to stop at the nearest node. If the unit is a firing unit and it has ammunition, it will go into a firing status unless it is immediately given another movement order.
If a fire unit is on the move, and the players want to hip-shoot the fire unit, then they must cancel the move command and issue a fire order. If any type unit is on the move and the players want to change the route or destination, then they must cancel the "move" command and then issue a new "move" command from the unit's new location.

3. Change Parameters

Selection of this option from the game control screen takes the players to more menus which give them the ability to change all the entries which were made during game setup except for the battalion configuration/status records. For example, the time step size can be changed, nodes and paths can be added to the network, and the situation report frequency can be changed. The battalion configuration records cannot be accessed because they contain the status of the battalion at the start of the game. To give the players the ability to edit these records would be the same as giving them the ability to circumvent the commands. If the players want to check a unit's status, they can use the "Request a Situation Report" command.

4. Network Utility

This option is not yet implemented. It is envisioned that this option will be used by the players to conduct movement planning. This option will eventually be capable of determining the shortest route by time or
distance and determining the safest route according to the path vulnerability levels.

5. **Output Game Statistics**

This option gives the players the ability to request the game’s statistics, MOE, and the number of rounds on-hand in excess of the battalion’s CSR at any point during the game. It is recommended that this listing be printed at least once at the end of every 24 hours of game play. This will provide a means of comparing statistics between games to judge if the players are improving in their ability to command and control the battalion. More will be said on the meaning of the statistics in Section F of this chapter.

5. **Quit**

Upon selecting the "Quit" option, the players are given two options. The first option is to quit with the intention of continuing the game later. This gives them the ability to continue the game where they left off at a later date. All of the appropriate files are saved to disk and are recalled the next time the game is played by selecting the "Continue an Old Game" option from the main menu. The second choice is to quit the game without the intention of ever continuing the game. In this case, the game’s data is not saved to disk.

In either case, the computer will provide a listing of the wargame’s statistics, the MOE, and the number of
rounds remaining in excess of the battalion’s CSR before returning to the MS-DOS "A:" prompt.

F. INTERPRETATION OF THE RESULTS

The "results" referred to in this section is the listing which is printed whenever the "Output Game Statistics" option or the "Quit" option is selected from the game play control screen (Figure 5.20). The listing itself should be self explanatory. It is the interpretation of the listing which requires some explanation.

Each time the listing is obtained, it is based on the cumulative statistics from the start of the game to the current time rather than since the last time the listing was obtained. Since this wargame does not allow replacements of casualties, the availability ratio will gradually decrease as time goes on due to casualties alone regardless of how well the players exercise command and control over the battalion. The same is true of the truck casualty ratio except that it will gradually increase. Since Lanchesterian attrition was used, this amount of change in the statistics should be consistent for the same wargame setup data and the same C2 decisions at any given amount of time into a particular game. Therefore, in order to be able to compare the performance between different groups of players playing the same game or between the same group of players playing the same game at two different times, they must obtain a printout of the statistics at the same amount of time into
the game during each game. For example, if the players request output of the statistics after every 24 hours of game play each time they play the game, they will be able to compare their performance from game to game. This is because the differences in the statistics for the same amount of time into each game will be due to command and control decisions made by the players. There will be no dependence on the amount of casualties which occur based simply on the amount of time the game has been played.

The ratios provide a measure of how well the players have performed with respect to the specific statistics involved in each ratio. For a better idea of how well the players have performed with respect to the overall command and control of the battalion, the Field Artillery Battalion Command and Control Effectiveness Index is used to determine a number which is based on all of the ratios. The number itself has no meaning other than as a means of comparing performance from one game to the next, assuming the same game setup data is used for each game. It can also be used to compare performance between two different groups of players each playing their own game when each game had the same setup data.

The final statistic is the number of rounds the battalion has on-hand in excess of the battalion's CSR. This statistic first counts all of the ammunition each firing unit has and then adds the amount of ammunition the
battalion has prepositioned in nodes. Even prepositioned ammunition which is currently behind enemy lines is included in the count because it is assumed that the loss of ammunition was a result of a poor command and control decision on the part of the players. The product of the battalion's CSR and the number of tubes in operating condition is then subtracted from the total count. The player's objective is to minimize this number. If the number is negative, the battalion has less than the CSR on-hand. The greater the number, the more rounds the battalion has on hand in excess of the CSR. Since it is assumed that the RSR equals the CSR in this game, large numbers would tend to indicate that the battalion did not properly project their required ammunition supply rate.

VI. SUGGESTED ENHANCEMENTS AND POTENTIAL USES

A. INTRODUCTION

The primary objective of this wargame has been achieved; to provide a tool for training officers in the integration of tactics and logistics as it relates to the command and control of a field artillery battalion. As with any undertaking of this kind, there is still plenty of room for improvements which would enhance the wargame’s effectiveness in training these officers. In spite of the need for improvement, the wargame, as it currently exists, is still very useful.

B. POTENTIAL WARGAME USES

It is very important to note, before discussing any of the wargame’s uses, that this game is not to be used as a tool to validate a unit’s war plans. This point cannot be emphasized enough. The game, while it was intended to be as realistic as possible, does not claim to accurately model casualty rates. It is primarily for this reason that the wargame should not be used to validate a unit’s war plans.

It is possible, however, to use the wargame as a tool to develop familiarity with a unit’s area of operations and its plans. By loading a unit movement network for a unit’s area of operations, the unit’s configuration into the battalion configuration file, the commander’s guidance into the
commander’s guidance file, and SOP / operations order items into the game parameter file, the players can exercise and become familiar with the unit’s general defense plans. Pre-hostility deployment plans, to include occupation of assembly areas followed by occupation of initial positions and pickup and delivery of the unit’s basic load of ammunition can easily be practiced. Just as easily, the unit’s post hostility plans can also be practiced. This type of training, using the unit’s actual wartime area of operations and battalion configuration, can pay great dividends if the plans are ever called upon to be used in time of war.

One of the strengths of the wargame is the ability for the computer assisted portion of the game to be integrated into any level of CPX. For example, the game can be played as a part of a battalion’s weekly officer professional development time, in conjunction with a battalion level CPX, or it can be integrated into a full scale, higher level, CPX. In every case, the utility of the game is that it allows the players to fully integrate tactical decisions with the logistics considerations. Additionally, it measures their performance using the Field Artillery Battalion Command and Control Effectiveness Index. By providing this feedback, the players can assess their decisions, and perhaps vary their method of command and control in order to maximize howitzer availability time,
minimize casualty time, vulnerability time, and time spent critically short of ammunition.

Another training strategy is to play the game competitively. For example, at the division artillery level, the game's setup files can be established so that they are the same for each battalion. Then, each battalion can play the game for a specified period of game time. At the end of the game, the game's statistics are assessed to determine which battalion more effectively command and controlled the wargame's units. A similar technique can be used for training within a battalion by playing the game competitively between the battalion's day and night shift personnel.

Finally, the game can be used by a battalion to study the effect on their tactics of increasing enemy lethality. By changing the value of "a" in the Lanchester equations found in the source code, the casualty rates can be changed. For each level of casualty rates, a set of tactics can be developed to more effectively command and control the battalion. The types of things which can be varied within the set of tactics include the size of ammunition convoys, the frequency and distance of moving firing units, the rate of firing for fire units, the use of point or unit distribution for ammunition resupply, the types of positions which are occupied (rural or urban), and the positioning of
the field trains in relation to the fire units and the ammunition transfer point.

C. IMPROVEMENTS / ENHANCEMENTS

The wargame, as it currently exists, is fully functional. However, there are some areas which can be expanded in order to make the wargame more useful. The enhancements described in the following paragraphs are listed in order of priority from highest to lowest.

1. Different Ammunition Types

Currently, the wargame allows the players to manage ammunition of only one type. While there are many things that can be learned about the integration of tactics and logistics when only using one ammunition type, the issues become much more complex when the myriad of possible ammunition types are included in the game. It is not only a logistics management problem, but also it has a profound impact on tactical planning.

In order to implement this enhancement, the fire unit, truck, and node records all will have to be modified to include each of the various ammunition types. Additionally, everywhere in the time step that ammunition is either transferred or expended, it must be done for each ammunition type. Finally, new criteria must be used to determine what constitutes low or critical ammunition levels.
2. Explicitly Play FLOT / Ranges

Currently, there is no cartesian coordinate system implemented within the wargame. This would not be difficult to implement and would enable certain useful functions. For example, it would enable the howitzer’s range to be played. Currently, it is up to the players to check the unit’s range fan against the battlefield geometry to determine if the unit needs to move due to range considerations. If the cartesian coordinate system were implemented, this would enable the computer to also check the range. If the players failed to move the unit as the FLOT moved out of range, then the unit would no longer be considered available. Other functions would be enabled as well by implementing this enhancement, range checks could be made for fire missions, unit positions could be overrun by the FLOT, and prepositioned ammunition could also be overrun by the FLOT.

In order to implement this enhancement, the node records need to be modified to include an X and Y coordinate for the UTM grid location of the node. Additionally, a record needs to be created for the coordinates of the FLOT, and procedures need to be written to calculate the distance between two points and to determine if a point lies above, below, left, or right of a line.

3. Requests for Fires

The way the wargame is now written, the players can fire a fire mission but the target is not explicitly named.
It is up to the players to ensure the target is within range before firing. Furthermore, the only impetus for firing comes from the players themselves, either to fire a fire plan directed by the operations order or to fire targets of opportunity generated by the players themselves. Since the players are assumed to be the battalion staff, the only types of fire missions which are played are battalion level missions or battery missions which are originated at the battalion level. All other firing is done by establishing a firing rate in terms of the CSR in order to expend the ammunition.

The first problem can be resolved by implementing the cartesian coordinate system. The second problem can be resolved by randomly generating requests for fires on randomly generated coordinates located on the far side of the FLOT. This process can be written to simulate FIREFINDER radar output or target lists from the division artillery target intelligence files. In either case, it would be up to the players to decide which targets to engage, which fire units to use, and with which ammunition types.

4. Play Fuel

Fuel was not played in this version of the wargame because fuel is already played in real training through actual consumption. Nevertheless, fuel is a very important
consideration in the integration of tactics and logistics. As such, it should be added to the wargame.

In order to implement this improvement, a similar approach to the one used for the ammunition resupply can be used. Rather than rounds of ammunition, resupply will be in gallons of fuel. Rather than a firing rate, consumption will be in terms of a rate based upon the unit’s posture, e.g. in position or moving. Like the ammunition trucks, fuel can be delivered by the combination of a movement command to the trucks or fire units and a resupply mission command.

Implementation of this command will ensure that the players do not move the units so much that they run out of fuel. It also forces them to plan for fuel resupply using either unit or point distribution thereby integrating the requirement for fuel into the battalion’s overall operational plan.

5. Play Maintenance

Like fuel, maintenance was not included in the first version of the wargame because it is regularly practiced in real training. It is, however, a real problem and therefore should be included in future versions of the game.

It can be implemented by forcing a certain amount of "down" time or maintenance time for every kilometer traveled by the battalion’s vehicles. This "down" time would then be subtracted from a fire unit’s availability time. For
ammunition trucks the "down" time could be handled similarly to the way that crew rest requirements are currently handled. In short, the truck would not be available for ammunition resupply missions while in a "down" status.

6. Network Utility

The network utility was assigned the lowest priority because it provides a service which is normally done manually by the players and it may be construed as detracting from the player's training. The network utility is intended to determine the shortest route (time or distance) between two nodes in the unit movement network or determine the safest route in terms of vulnerability factors. It can be used as a staff planning aid in determining unit movement routes or it can be used to automate the movement orders by allowing the players to specify that a move between two nodes be done using the shortest or safest route.

The node and path records needed for this enhancement are already in place. All that is needed are procedures containing the appropriate algorithms to implement the functions.

D. FINAL COMMENTS

At the very least, this wargame can serve as a working prototype for a wargame to train officers in the integration of tactics and logistics as related to the command and control of a field artillery battalion. The word "working"
is emphasized because this wargame, as currently implemented, is fully operational and is capable of use by units in the field. The wargame's greatest strengths are that it requires very little training on the use of the wargame itself, it can be played on an IBM compatible personal computer, it uses the Field Artillery Battalion Command and Control Effectiveness Index to provide feedback, and it forces the players to consider aspects of field artillery battalion command and control which are very difficult if not impossible to practice through actual training.

Finally, it should be pointed out that this wargame was originally conceived to satisfy a perceived deficiency in training which is common to all units that require large quantities of bulk supplies, such as ammunition, to sustain them in combat. The point is that this wargame, with relatively minor changes, could be used for air defense artillery units, armor units, and infantry units. In short, the concept can be expanded into a whole class of wargames which can be used by battalion level officers for training in the integration of tactics and logistics.
APPENDIX

DOCUMENTED SOURCE CODE

(******************************************************************************)
{
Program name: WARGAME
Purpose: this program is a computer assisted wargame designed to exercise the command and control functions in a field artillery battalion as they relate to the integration of tactics and logistics.
Written by: Anthony R. Ferrara
Michael W. Schneider
Program completed: 23 March 1989
Language used: Turbo Pascal 5.0
System: IBM Personal System II Model 50 running DOS 3.30
Environment required: IBM compatible system with color monitor.

Program structure:
this program makes extensive use of the unit structure defined by Turbo pascal. All of the procedures, functions, and variables of the program are contained in the units that are part of this program.

Units:
GLOBAL - this unit contains the declarations for all of the files, records and variables used for the game itself.
GAME - this is the unit responsible for the overall control of the game: its initialization, modification of parameters, execution of the game, and issuing of commands.
INIT - contains the procedures that initialize the game and allow the user to change any of the games parameters.
SCENARIO - contains the procedures that initialize, modify, and create the scenario for the game.
TIMESTEP - this unit contains the procedures that comprise the "heart" of the game, it actually executes each time step and processes the event records for the game.
COMMANDS - this unit contains the procedures

126
that allow the user to issue commands that allow the command and control of an artillery battalion to take place.

GAMEUTIL - this unit contains a number of general purpose utility procedures and functions that are used by more than one unit and are specific to the game.

UTILITY - this unit contains a library of general purpose procedures that are specifically for the generation of the user interface, both input and output.

TACCESS - this a Borland written unit that contains a number of low level procedures that provide database related functions used throughout the game.

TAHIGH - this a Borland written unit that contains a number of high level procedures that provide database related functions used throughout the game.

(*----------------------------------------*)

Unit name: GAME

Purpose: this unit contains the procedures that actually comprise the heart of the wargame. It is responsible for initializing either a new or old game, running the game, and taking care of the functions necessary when quitting. As part of the game itself it also controls execution of the time step, the issuing of commands, and the changing of allowable game parameters for the execution of the game. This unit can be thought of as having four subordinate units that contains the procedures that carry out its functions. These are INIT, SCENARIO, TIMESTEP, and COMMANDS.

(*----------------------------------------*)

unit game;

interface
($I-$)

uses crt, printer, utility, gameutil, global, init, scenario, timestep, commands, taccess, tahigh;

procedure play_new_game;
procedure play_old_game;

implementation
(*----------------------------------------*)

{ Procedure name: PLAY_WARGAME

Purpose: this procedure controls the play of wargame once it has been initialized as either a new or old game, as appropriate. It displays the game screen, and provides the game menu. It relies on four units: INIT, SCENARIO, TIMESTEP, and COMMANDS. These are called as is necessary to handle the selection made from the game menu by the player.

Parameters: none.

Called by: PLAY_NEW_GAME
           PLAY_OLD_GAME

(*----------------------------------------*)

procedure play_wargame;
var
  choice : integer;

(* ***********************************************************************)
{ Procedure name : DISPLAY_GAME_MAIN_SCREEN

Purpose : this procedure displays the current
          game time in large block letters at the top
          of the screen and the current dtg in normal
          size characters on the top line of the screen.

Parameters : none.

Called by : PLAY_WARGAME
             EXECUTE_NEXT_TIME_STEP
}

{ Procedure name: DTG_TO_TIMEKEY }

Purpose: this procedure takes a string that is a valid dtg and converts it to a string that contains the same information but can be used as an alphabetic key for event records.

Parameters: DTG - string that contains the valid dtg to converted for use as a key.
TIMEKEY - string that will contain the key after conversion from dtg format.

Called by:

procedure dtg_to_timekey (dtg : string15; var timekey : string10);

var
    month : month_type;
    month_val : string;

```
begin
dtg := remove_blanks (dtg);
