This Validation Summary Report (VSR) describes the extent to which a specific Ada compiler conforms to the Ada Standard, ANSI/MIL-STD-1815A. This report explains all technical terms used within it and thoroughly reports the results of testing this compiler using the Ada Compiler Validation Capability (ACVC). An Ada compiler must be implemented according to the Ada Standard, and any implementation-dependent features must conform to the requirements of the Ada Standard. The Ada Standard must be implemented in its entirety, and nothing can be implemented that is not in the Standard.

Even though all validated Ada compilers conform to the Ada Standard, it must be understood that some differences do exist between implementations. The Ada Standard permits some implementation dependencies—for example, the maximum length of identifiers or the maximum values of integer types. Other differences between compilers result from the characteristics of particular operating systems, hardware, or implementation strategies. All the dependencies observed during the process of testing this compiler are given in this report.

The information in this report is derived from the test results produced during validation testing. The validation process includes submitting a suite of standardized tests, the ACVC, as inputs to an Ada compiler and evaluating the results. The purpose of validating is to ensure conformity of the compiler to the Ada Standard by testing that the compiler properly implements legal language constructs and that it identifies and rejects illegal language constructs. The testing also identifies behavior that is implementation dependent, but is permitted by the Ada Standard. Six classes of tests are used. These tests are designed to perform checks at compile time, at link time, and during execution.

1.1 PURPOSE OF THIS VALIDATION SUMMARY REPORT

This VSR documents the results of the validation testing performed on an Ada compiler. Testing was carried out for the following purposes:
. To attempt to identify any language constructs supported by the compiler that do not conform to the Ada Standard

. To attempt to identify any language constructs not supported by the compiler but required by the Ada Standard

. To determine that the implementation-dependent behavior is allowed by the Ada Standard

Testing of this compiler was conducted by IABG mbH, Abt SZT according to procedures established by the Ada Joint Program Office and administered by the Ada Validation Organization (AVO). On-site testing was completed 12 April 1989 at IABG mbH, Ottobrunn.

1.2 USE OF THIS VALIDATION SUMMARY REPORT

Consistent with the national laws of the originating country, the AVO may make full and free public disclosure of this report. In the United States, this is provided in accordance with the "Freedom of Information Act" (5 U.S.C. #552). The results of this validation apply only to the computers, operating systems, and compiler versions identified in this report.

The organizations represented on the signature page of this report do not represent or warrant that all statements set forth in this report are accurate and complete, or that the subject compiler has no nonconformities to the Ada Standard other than those presented. Copies of this report are available to the public from:

Ada Information Clearinghouse
Ada Joint Program Office
OUSDRE
The Pentagon, Rm 3D-139 (Fern Street)
Washington DC 20301-3081

or from:

IABG mbH, Abt SZT
Einsteinstr 20

1.3 REFERENCES

1.4 DEFINITION OF TERMS

ACVC The Ada Compiler Validation Capability. The set of Ada programs that tests the conformity of an Ada compiler to the Ada programming language.

Ada Commentary An Ada Commentary contains all information relevant to the point addressed by a comment on the Ada Standard. These comments are given a unique identification number having the form AI-ddddd.

Applicant The agency requesting validation.

AVF The Ada Validation Facility. The AVF is responsible for conducting compiler validations according to procedures contained in the Ada Compiler Validation Procedures and Guidelines.

AVO The Ada Validation Organization. The AVO has oversight authority over all AVF practices for the purpose of maintaining a uniform process for validation of Ada compilers. The AVO provides administrative and technical support for Ada validations to ensure consistent practices.

Compiler A processor for the Ada language. In the context of this report, a compiler is any language processor, including cross-compilers, translators, and interpreters.

Failed test An ACVC test for which the compiler generates a result that demonstrates nonconformity to the Ada Standard.

Host The computer on which the compiler resides.
**Inapplicable Test**
An ACVC test that uses features of the language that a compiler is not required to support or may legitimately support in a way other than the one expected by the test.

**Passed Test**
An ACVC test for which a compiler generates the expected result.

**Target**
The computer which executes the code generated by the compiler.

**Test**
A program that checks a compiler's conformity regarding a particular feature or a combination of features to the Ada Standard. In the context of this report, the term is used to designate a single test, which may comprise one or more files.

**Withdrawn Test**
An ACVC test found to be incorrect and not used to check conformity to the Ada Standard. A test may be incorrect because it has an invalid test objective, fails to meet its test objective, or contains illegal or erroneous use of the language.

### 1.5 ACVC TEST CLASSES

Conformity to the Ada Standard is measured using the ACVC. The ACVC contains both legal and illegal Ada programs structured into six test classes: A, B, C, D, E, and L. The first letter of a test name identifies the class to which it belongs. Class A, C, D, and E tests are executable, and special program units are used to report their results during execution. Class B tests are expected to produce compilation errors. Class L tests are expected to produce errors because of the way in which a program library is used at link time.

**Class A tests** ensure the successful compilation and execution of legal Ada programs with certain language constructs which cannot be verified at runtime. There are no explicit program components in a Class A test to check semantics. For example, a Class A test checks that reserved words of another language (other than those already reserved in the Ada language) are not treated as reserved words by an Ada compiler. A Class A test is passed if no errors are detected at compile time and the program executes to produce a PASSED message.

**Class B tests** check that a compiler detects illegal language usage. Class B tests are not executable. Each test in this class is compiled and the resulting compilation listing is examined to verify that every syntax or semantic error in the test is detected. A Class B test is passed if every illegal construct that it contains is detected by the compiler.
Class C tests check the run time system to ensure that legal Ada programs can be correctly compiled and executed. Each Class C test is self-checking and produces a PASSED, FAILED, or NOT APPLICABLE message indicating the result when it is executed.

Class D tests check the compilation and execution capacities of a compiler. Since there are no capacity requirements placed on a compiler by the Ada Standard for some parameters—for example, the number of identifiers permitted in a compilation or the number of units in a library—a compiler may refuse to compile a Class D test and still be a conforming compiler. Therefore, if a Class D test fails to compile because the capacity of the compiler is exceeded, the test is classified as inapplicable. If a Class D test compiles successfully, it is self-checking and produces a PASSED or FAILED message during execution.

Class E tests are expected to execute successfully and check implementation-dependent options and resolutions of ambiguities in the Ada Standard. Each Class E test is self-checking and produces a NOT APPLICABLE, PASSED, or FAILED message when it is compiled and executed. However, the Ada Standard permits an implementation to reject programs containing some features addressed by Class E tests during compilation. Therefore, a Class E test is passed by a compiler if it is compiled successfully and executes to produce a PASSED message, or if it is rejected by the compiler for an allowable reason.

Class L tests check that incomplete or illegal Ada programs involving multiple, separately compiled units are detected and not allowed to execute. Class L tests are compiled separately and execution is attempted. A Class L test passes if it is rejected at link time—that is, an attempt to execute the main program must generate an error message before any declarations in the main program or any units referenced by the main program are elaborated. In some cases, an implementation may legitimately detect errors during compilation of the test.

Two library units, the package REPORT and the procedure CHECK_FILE, support the self-checking features of the executable tests. The package REPORT provides the mechanism by which executable tests report PASSED, FAILED, or NOT APPLICABLE results. It also provides a set of identity functions used to defeat some compiler optimizations allowed by the Ada Standard that would circumvent a test objective. The procedure CHECK_FILE is used to check the contents of text files written by some of the Class C tests for Chapter 14 of the Ada Standard. The operation of REPORT and CHECK_FILE is checked by a set of executable tests. These tests produce messages that are examined to verify that the units are operating correctly. If these units are not operating correctly, then the validation is not attempted.

The text of each test in the ACVC follows conventions that are intended to ensure that the tests are reasonably portable without modification. For example, the tests make use of only the basic set of 55 characters, contain lines with a maximum length of 72 characters, use small numeric values, and tests. However, some tests contain values that require the test to be
customized according to implementation-specific values--for example, an illegal file name. A list of the values used for this validation is provided in Appendix C.

A compiler must correctly process each of the tests in the suite and demonstrate conformity to the Ada Standard by either meeting the pass criteria given for the test or by showing that the test is inapplicable to the implementation. The applicability of a test to an implementation is considered each time the implementation is validated. A test that is inapplicable for one validation is not necessarily inapplicable for a subsequent validation. Any test that was determined to contain an illegal language construct or an erroneous language construct is withdrawn from the ACVC and, therefore, is not used in testing a compiler. The tests withdrawn at the time of this validation are given in Appendix D.
2.1 CONFIGURATION TESTED

The candidate compilation system for this validation was tested under the following configuration:

Compiler: TARTAN ADA Sun/Sun Version 2.1
ACVC Version: 1.10
Certificate Number: E90412I1.10082

Host Computer:
  Machine: SUN 3/60
  Operating System: SUN OS Version 3.5
  Memory Size: 8 MB

Target Computer:
  Machine: SUN 3/60
  Operating System: SUN OS Version 3.5
  Memory Size: 8 MB
2.2 IMPLEMENTATION CHARACTERISTICS

One of the purposes of validating compilers is to determine the behavior of a compiler in those areas of the Ada Standard that permit implementations to differ. Class D and E tests specifically check for such implementation differences. However, tests in other classes also characterize an implementation. The tests demonstrate the following characteristics:

a. Capacities.

1) The compiler correctly processes a compilation containing 723 variables in the same declarative part. (See test D29002K.)

2) The compiler correctly processes tests containing loop statements nested to 65 levels. (See tests D55A03A..H (8 tests).)

3) The compiler correctly processes tests containing block statements nested to 65 levels. (See test D56001B.)

4) The compiler correctly processes tests containing recursive procedures separately compiled as subunits nested to 17 levels. (See tests D64005E..G (3 tests).)

b. Predefined types.

1) This implementation supports the additional predefined types SHORT INTEGER, BYTE INTEGER, and LONG FLOAT in the package STANDARD. (See tests B86001T..Z (7 tests).)

c. Expression evaluation.

The order in which expressions are evaluated and the time at which constraints are checked are not defined by the language. While the ACVC tests do not specifically attempt to determine the order of evaluation of expressions, test results indicate the following:

1) None of the default initialization expressions for record components are evaluated before any value is checked for membership in a component's subtype. (See test C32117A.)

2) Assignments for subtypes are performed with the same precision as the base type. (See test C35712B.)
3) This implementation uses no extra bits for extra precision and uses all extra bits for extra range. (See test C35903A.)

4) NUMERIC_ERROR is raised for predefined and largest integer and no exception is raised for smallest integer when an integer literal operand in a comparison or membership test is outside the range of the base type. (See test C45232A.)

5) No exception is raised when a literal operand in a fixed-point comparison or membership test is outside the range of the base type. (See test C45252A.)

6) Underflow is gradual. (See tests C45524A..Z (26 tests).)

d. Rounding.

The method by which values are rounded in type conversions is not defined by the language. While the ACVC tests do not specifically attempt to determine the method of rounding, the test results indicate the following:

1) The method used for rounding to integer is round to even. (See tests C46012A..Z (26 tests).)

2) The method used for rounding to longest integer is round to even. (See tests C46012A..Z (26 tests).)

3) The method used for rounding to integer in static universal real expressions is round to even. (See test C4A014A.)

e. Array types.

An implementation is allowed to raise NUMERIC_ERROR or CONSTRAINT_ERROR for an array having a 'LENGTH that exceeds STANDARD.INTEGER'LAST and/or SYSTEM.MAX_INT. For this implementation:

1) Declaration of an array type or subtype declaration with more than SYSTEM.MAX_INT components raises NUMERIC_ERROR for one dimensional array types, two dimensional array types and two dimensional array subtypes, and no exception for one dimensional array subtypes. (See test C36003A.)

2) NUMERIC_ERROR is raised when an array type with INTEGER'LAST + 2 components is declared. (See test C36202A.)
3) **NUMERIC_ERROR** is raised when an array type with `SYSTEM.MAX_INT + 2` components is declared. (See test C36202B.)

4) A packed BOOLEAN array having a 'LENGTH exceeding INTEGER'LAST raises NUMERIC_ERROR when the array type is declared. (See test C52103X.)

5) A packed two-dimensional BOOLEAN array with more than INTEGER'LAST components raises NUMERIC_ERROR when the array type is declared and exceeds INTEGER'LAST. (See test C52104Y.)

6) In assigning one-dimensional array types, the expression is not evaluated in its entirety before CONSTRAINT_ERROR is raised when checking whether the expression's subtype is compatible with the target's subtype. (See test C52013A.)

7) In assigning two-dimensional array types, the expression is not evaluated in its entirety before CONSTRAINT_ERROR is raised when checking whether the expression's subtype is compatible with the target's subtype. (See test C52013A.)

8) A null array with one dimension of length greater than INTEGER'LAST may raise NUMERIC_ERROR or CONSTRAINT_ERROR either when declared or assigned. Alternatively, an implementation may accept the declaration. However, lengths must match in array slice assignments. This implementation raises NUMERIC_ERROR when the array type is declared. (See test E52103Y.)

f. Discriminated types.

1) In assigning record types with discriminants, the expression is evaluated in its entirety before CONSTRAINT_ERROR is raised when checking whether the expression's subtype is compatible with the target's subtype. (See test C52013A.)

g. Aggregates.

1) In the evaluation of a multi-dimensional aggregate, the test results indicate that all choices are evaluated before checking against the index type. (See tests C43207A and C43207B.)

2) In the evaluation of an aggregate containing subaggregates, not all choices are evaluated before being checked for identical bounds. (See test E43212B.)
3) CONSTRAINT_ERROR is raised after all choices are evaluated when a bound in a non-null range of a non-null aggregate does not belong to an index subtype. (See test E43211E.)

h. Pragmas.

1) The pragma INLINE is supported for functions and procedures but not when applied across compilation units. (See tests LA3004A..B (2 tests), EA3004C..D (2 tests), and CA3004E..F (2 tests).)

i. Generics.

This compiler enforces the following two rules concerning declarations and proper bodies which are individual compilation units:

- generic bodies must be compiled and completed before their instantiation.
- recompilation of a generic body or any of its transitive subunits makes all units obsolete which instantiate that generic body.

These rules are enforced whether the compilation units are in separate compilation files or not. A1408 and A1506 allow this behaviour.

1) Generic specifications and bodies can be compiled in separate compilations. (See tests CA1012A, CA2009C, CA2009F, BC3204C, and BC3205D.)

2) Generic subprogram declarations and bodies can be compiled in separate compilations. (See tests CA1012A and CA2009F.)

3) Generic library subprogram specifications and bodies be compiled in separate compilations. (See test CA1012A.)

4) Generic non-library package bodies as subunits can be compiled in separate compilations. (See test CA2009C.)

5) Generic non-library subprogram bodies can be compiled in separate compilations from their stubs. (See test CA2009F.)
6) Generic unit bodies and their subunits can be compiled in separate compilations. (See test CA3011A.)

7) Generic package declarations and bodies can be compiled in separate compilations. (See tests CA2009C, BC3204C, and BC3205D.)

8) Generic library package specifications and bodies can be compiled in separate compilations. (See tests BC3204C and BC3205D.)

9) Generic unit bodies and their subunits can be compiled in separate compilations. (See test CA3011A.)

j. Input and output.

1) The package SEQUENTIAL_IO cannot be instantiated with unconstrained array types or record types with discriminants without defaults. (See tests AE2101C, EE2201D, and EE2201E.)

2) The package DIRECT_IO cannot be instantiated with unconstrained array types or record types with discriminants without defaults. (See tests AE2101H, EE2401D, and EE2401G.)

3) Modes IN_FILE and OUT_FILE are supported for SEQUENTIAL_IO. (See tests CE2102D..E, CE2102N, and CE2102P.)

4) Modes IN_FILE, OUT_FILE, and INOUT_FILE are supported for DIRECT_IO. (See tests CE2102F, CE2102I..J (2 tests), CE2102K, CE2102T, and CE2102V.)

5) Modes IN_FILE and OUT_FILE are supported for text files. (See tests CE3102E and CE3102I..K (3 tests).)

6) RESET and DELETE operations are supported for SEQUENTIAL_IO. (See tests CE2102G and CE2102X.)

7) RESET and DELETE operations are supported for DIRECT_IO. (See tests CE2102K and CE2102Y.)

8) RESET and DELETE operations are supported for text files. (See tests CE3102F..G (2 tests), CE3104C, CE3110A, and CE3114A.)

9) Overwriting to a sequential file truncates to the last element written. (See test CE2208B.)
10) Temporary sequential files are given names and deleted when closed. (See test CE2108A.)

11) Temporary direct files are given names and deleted when closed. (See test CE2108C.)

12) Temporary text files are given names and deleted when closed. (See test CE3112A.)

13) More than one internal file can be associated with each external file for sequential files when writing or reading. (See tests CE2107A..E (5 tests), CE2102L, CE2110B, and CE2111D.)

14) More than one internal file can be associated with each external file for direct files when writing or reading. (See tests CE2107F..H (3 tests), CE2110D and CE2111H.)

15) More than one internal file can be associated with each external file for text files when reading only or when writing only. (See tests CE3111A..E (5 tests), CE3114B, and CE3115A.)
3.1 TEST RESULTS

Version 1.10 of the ACVC comprises 3717 tests. When this compiler was tested, 43 tests had been withdrawn because of test errors. The AVF determined that 290 tests were inapplicable to this implementation. All inapplicable tests were processed during validation testing except for 201 executable tests that use floating-point precision exceeding that supported by the implementation. Modifications to the code, processing, or grading for 81 tests were required to successfully demonstrate the test objective. (See section 3.6.)

The AVF concludes that the testing results demonstrate acceptable conformity to the Ada Standard.

3.4 WITHDRAWN TESTS

The following 43 tests were withdrawn from ACVC Version 1.10 at the time of this validation:

E28005C A39005G B97102E BC3009B CD2A62D CD2A63A
CD2A63B CD2A63C CD2A63D CD2A66A CD2A66B CD2A66C
CD2A66D CD2A73A CD2A73B CD2A73C CD2A73D CD2A76A
CD2A76B CD2A76C CD2A76D CD2A81G CD2A83G CD2A84N
CD2A84M CD50110 CD2B15C CD7205C CD7205D CT2D12B CD5007B
ED7004B ED7005C ED7005D ED7006C ED7006D CD7105A
CD7203B CD7204B CD7205D CE2107I CE3111C CE3301A
CE3411B

See Appendix D for the reason that each of these tests was withdrawn.

3.5 INAPPLICABLE TESTS

Some tests do not apply to all compilers because they make use of features that a compiler is not required by the Ada Standard to support. Others may depend on the result of another test that is either inapplicable or withdrawn. The applicability of a test to an implementation is considered each time a validation is attempted. A test that is inapplicable for one validation attempt is not necessarily inapplicable for a subsequent attempt. For this validation attempt, 290 tests were inapplicable for the reasons indicated:

a. The following 201 tests are not applicable because they have floating-point type declarations requiring more digits than SYSTEM.MAX_DIGITS:

C24113L..Y (14 tests) C35705L..Y (14 tests)
C35706L..Y (14 tests) C35707L..Y (14 tests)
b. C35702A and B86001T are not applicable because this implementation supports no predefined type SHORT_FLOAT.

c. The following 16 tests are not applicable because this implementation does not support a predefined type LONG_INTEGER:

   C45231C  C45304C  C45502C  C45503C  C45504C
   C45504F  C45611C  C45613C  C45614C  C45631C
   C45632C  B52004D  C55B07A  B55B09C  B86001W
   CD7101F

d. C86001F is not applicable because, for this implementation, the package TEXT_IO is dependent upon package SYSTEM. These tests recompile package SYSTEM, making package TEXT_IO, and hence package REPORT, obsolete.

e. B86001Y is not applicable because this implementation supports no predefined fixed-point type other than DURATION.

f. B86001Z is not applicable because this implementation supports no predefined floating-point type with a name other than FLOAT, LONG_FLOAT, or SHORT_FLOAT.

g. CA2009A, CA2009C, CA2009F and CA2009D are not applicable because this compiler creates dependancies between generic bodies, and units that instantiate them (see section 2.21 for rules and restrictions concerning generics).

h. LA3004A, LA3004B, EA3004C, EA3004D, CA3004E, and CA3004F are not applicable because this implementation does not support pragma INLINE when applied across compilation units (See Appendix F of the Ada Standard in Appendix B of this report, and Section 2.2.h (1)).

i. CD1009C and CD2A41A..J (10 tests) are not applicable because this implementation imposes restrictions on 'SIZE length clauses for floating point types.

j. CD2A61I is not applicable because this implementation imposes restrictions on 'SIZE length clauses for array types.

k. CD2A84B..I (8 tests) and CD2A84K..L (2 tests) are not applicable because this implementation imposes restrictions on 'SIZE length clauses for access types.
1. CD2A91A..E (5 tests) are not applicable because 'SIZE length clauses for task types are not supported.

2. CD2B111G is not applicable because 'STORAGE SIZE representation clauses are not supported for access types where the designated type is a task type.

3. CD2B115B is not applicable because a collection size larger than the size specified was allocated.

4. AE2101C, EE2201D, and EE2201E use instantiations of package SEQUENTIAL_IO with unconstrained array types and record types with discriminants without defaults. These instantiations are rejected by this compiler.

5. AE2101H, EE2401D, and EE2401G use instantiations of package DIRECT_IO with unconstrained array types and record types with discriminants without defaults. These instantiations are rejected by this compiler.

6. CE2102D is inapplicable because this implementation supports CREATE with IN_FILE mode for SEQUENTIAL_IO.

7. CE2102E is inapplicable because this implementation supports CREATE with OUT_FILE mode for SEQUENTIAL_IO.

8. CE2102F is inapplicable because this implementation supports CREATE with INOUT_FILE mode for DIRECT_IO.

9. CE2102I is inapplicable because this implementation supports CREATE with IN_FILE mode for DIRECT_IO.

10. CE2102J is inapplicable because this implementation supports CREATE with OUT_FILE mode for DIRECT_IO.

11. CE2102N is inapplicable because this implementation supports OPEN with IN_FILE mode for SEQUENTIAL_IO.

12. CE2102O is inapplicable because this implementation supports RESET with IN_FILE mode for SEQUENTIAL_IO.

13. CE2102P is inapplicable because this implementation supports OPEN with OUT_FILE mode for SEQUENTIAL_IO.

14. CE2102Q is inapplicable because this implementation supports RESET with OUT_FILE mode for SEQUENTIAL_IO.

15. CE2102R is inapplicable because this implementation supports OPEN with INOUT_FILE mode for DIRECT_IO.
aa. CE2102S is inapplicable because this implementation supports RESET with INOUT_FILE mode for DIRECT_IO.

ab. CE2102T is inapplicable because this implementation supports OPEN with IN_FILE mode for DIRECT_IO.

ac. CE2102U is inapplicable because this implementation supports RESET with IN_FILE mode for DIRECT_IO.

ad. CE2102V is inapplicable because this implementation supports OPEN with OUT_FILE mode for DIRECT_IO.

ae. CE2102W is inapplicable because this implementation supports RESET with OUT_FILE mode for DIRECT_IO.

af. CE3102E is inapplicable because text file CREATE with IN_FILE mode is supported by this implementation.

ag. CE3102F is inapplicable because text file RESET is supported by this implementation.

ah. CE3102G is inapplicable because text file deletion of an external file is supported by this implementation.

ai. CE3102I is inapplicable because text file CREATE with OUT_FILE mode is supported by this implementation.

aj. CE3102J is inapplicable because text file OPEN with IN_FILE mode is supported by this implementation.

ak. CE3102K is inapplicable because text file OPEN with OUT_FILE mode is not supported by this implementation.

al. CE3111B and CE3115A open two internal files, both of which correspond to the same external file. The tests PUT a string to the first internal file, and then try to read this string from the second internal file.

This implementation raises END_ERROR upon executing the GET statement because of the use of buffers which are not flushed until the output of a line of page terminator. Due to LRM 14.1 (13), the AVO ruled these tests not applicable.
3.6 TEST, PROCESSING, AND EVALUATION MODIFICATIONS

It is expected that some tests will require modifications of code, processing, or evaluation in order to compensate for legitimate implementation behavior. Modifications are made by the AVF in cases where legitimate implementation behavior prevents the successful completion of an (otherwise) applicable test. Examples of such modifications include: adding a length clause to alter the default size of a collection; splitting a Class B test into subtests so that all errors are detected; and confirming that messages produced by an executable test demonstrate conforming behavior that was not anticipated by the test (such as raising one exception instead of another).

Modifications were required for 81 tests.

a. The following tests were split because syntax errors at one point resulted in the compiler not detecting other errors in the test:

   B22003A  B24007A  B24009A  B25002B  B32201A  B34005N
   B34005T  B34007H  B35701A  B36171A  B36201A  B37101A
   B37102A  B37201A  B37202A  B37203A  B37302A  B38003A
   B38003B  B38008A  B38008B  B38009A  B38009B  B38103A
   B38103B  B38103C  B38103D  B38103E  B43202C  B44002A
   B48002A  B48002B  B48103D  B48103E  B48202C  B48202G
   B49003A  B49005A  B49006A  B49007A  B49009A  B4AC10C
   B54A20A  B54A25A  B58002A  B58002B  B59001A  B59001C
   B59001I  B62006C  B67001A  B67001B  B67001C  B67001D
   B74103E  B74104A  B85007C  B91005A  B95003A  B95007B
   B95031A  B95074E  BC1002A  BC1009A  BC1109A  BC1109C
   BC1206A  BC2001E  BC3005B  BC3009C  BD5005B

b. For the two tests BC3204C and BC3205D, the compilation order was changed to

   BC3204C0, C1, C2, C3M, C4, C5, C6, C3M
   BC3205DO, D2, D1M

   respectively. This change was necessary because of the compiler's rules for separately compiled generic units (see section 2.2i for rules and restrictions concerning generics). When processed in this order the expected error messages were produced for BC3204C3M and BC3205D1M.

c. The two tests BC3204D and BC3205C consist of several compilation units each. The compilation units for the main procedures are near the beginning of the files. When processing these files unchanged, a link error is reported instead of the expected compiled generic units. Therefore, the compilation files were modified by appending copies of the main procedures to the end of
these files. When processed, the expected error messages were
generated by the compiler.

d. Tests C39005A, CD7004C, CD7005E and CD7006E wrongly presume an
order of elaboration of the library unit bodies. These tests were
modified to include a PRAGMA ELABORATE (REPORT):

e. Test E28002B checks that predefined or unrecognized pragmas may
have arguments involving overloaded identifiers without enough
contextual information to resolve the overloading. It also checks
the correct processing of pragma LIST. For this implementation,
pragma LIST is only recognised if the compilation file is compiled
without errors or warnings. Hence, the test was modified to
demonstrate the correct processing of pragma LIST.

f. Tests C45524A and C45524B contain a check at line 136 that may
legitimately fail as repeated division may produce a quotient that
lies within the smallest safe interval. This check was modified
to include, after line 138, the text:

ELSIF VAL <= F'SAFE_SMALL THEN COMMENT ("UNDERFLOW SEEMS GRADUAL");

For this implementation, the required support package specification,
SPPRT13SP, was rewritten to provide constant values for the function names.

3.7 ADDITIONAL TESTING INFORMATION

3.7.1 Prevalidation

Prior to validation, a set of test results for ACVC Version 1.10 produced
by the TARTAN ADA Sun/Sun Version 2.1 compiler was submitted to the AVF
by the applicant for review. Analysis of these results demonstrated that
the compiler successfully passed all applicable tests, and the
compiler exhibited the expected behavior on all inapplicable tests.

3.7.2 Test Method

Testing of the TARTAN ADA Sun/Sun Version 2.1 compiler using ACVC
Version 1.10 was conducted by IABG on the premises of IABG. The
configuration in which the testing was performed is described by the
following designations of hardware and software components:

- Host computer: SUN 3/60
- Host operating system: SUN OS Version 3.5
- Target computer: SUN 3/60
- Target operating system: SUN OS Version 3.5
- Compiler: TARTAN ADA Sun/Sun Version 2.1

The original ACVC distribution tape was loaded to a VAX 8350, where it was
customized to remove all withdrawn tests and tests requiring unsupported
floating point precisions. Tests that make use of implementation specific
values were also customized. Tests requiring modifications during the prevalidation testing were modified accordingly.

The customized ACVC was then transferred to the host computer via an Ethernet connection.

After the test files were loaded to disk, the full set of tests was compiled linked, and all executable tests were run on the SUN i/60. Results were transferred via an Ethernet connection to a VAX 8350, where they were evaluated and printed.

The compiler was tested using command scripts provided by TARTAN LABORATORIES INCORPORATED and reviewed by the validation team. The compiler was tested using no option settings. All chapter B tests were compiled with the listing option on (i.e. -La). The linker was called with the command

```
alib link (testname)
```

A full list of compiler and linker options is given in Appendix E.

Tests were compiled, linked, and executed (as appropriate) using a single computer. Test output, compilation listings, and job logs were captured on magnetic tape and archived at the AVF. The listings examined on-site by the validation team were also archived.

3.7.3 Test Site

Testing was conducted at IABG mbH, Ottobrunn and was completed on 12 April 1989.
APPENDIX A

DECLARATION OF CONFORMANCE

TARTAN LABORATORIES INCORPORATED has submitted the following Declaration of Conformance concerning the TARTAN ADA Sun/Sun Version 2.1 compiler.
DECLARATION OF CONFORMANCE

Compiler Implementor: Tartan Laboratories Incorporated
Ada Validation Facility: IABG mbH, Dept. SZT
Ada Compiler Validation Capability (ACVC) Version: 1.10

Base Configuration

Base Compiler Name: Tartan Ada Sun/Sun Version 2.1
Host Architecture: Sun 3/60
Host OS and Version: Sun OS Version 3.5
Target Architecture: Sun 3/60
Target OS and Version: Sun OS Version 3.5

Implementor's Declaration

I, the undersigned, representing Tartan Laboratories Incorporated, have implemented no deliberate extensions to the Ada Language Standard ANSI/MIL-STD-1815A in the compiler(s) listed in this declaration. I declare that Tartan Laboratories Incorporated is the owner of record of the Ada Language compiler(s) listed above and, as such, is responsible for maintaining said compiler(s) in conformance to ANSI/MIL-STD-1815A. All certificates and registrations for Ada Language compiler(s) listed in this declaration shall be made only in the owner's corporate name.

Tartan Laboratories Incorporated
D. L. Evans, President

Date: 2 May 89

Owner's Declaration

I, the undersigned, representing Tartan Laboratories Incorporated, take full responsibility for implementation and maintenance of the Ada compiler(s) listed above, and agree to the public disclosure of the final Validation Summary Report. I declare that all of the Ada Language compilers listed, and their host/target performance, are in compliance with the Ada Language Standard ANSI/MIL-STD-1815A.

Tartan Laboratories Incorporated
D. L. Evans, President

Date: 2 May 89
The only allowed implementation dependencies correspond to implementation-dependent pragmas, to certain machine-dependent conventions as mentioned in chapter 13 of the Ada Standard, and to certain allowed restrictions on representation clauses. The implementation-dependent characteristics of the TARTAN ADA Sun/Sun Version 2.1 compiler, as described in this Appendix, are provided by TARTAN LABORATORIES INCORPORATED. Unless specifically noted otherwise, references in this appendix are to compiler documentation and not to this report. Implementation-specific portions of the package STANDARD, are contained in Appendix F.
Chapter 5
Appendix F to MIL-STD-1815A

5.1. PRAGMAS

5.1.1. Predefined Pragmas
This section summarizes the effects of and restrictions on predefined pragmas.

- Access collections are not subject to automatic storage reclamation so pragma CONTROLLED has no effect. Space deallocated by means of UNCHECKED Deallocation will be reused by the allocation of new objects.
- Pragma ELABORATE is fully supported.
- Pragma INLINE is supported but has an effect on the generated code only when the call appears within the same compilation unit as the body of the in-lined subprogram.
- Pragma INTERFACE is not supported. The implementation-defined pragma FOREIGN_BODY (see Section 5.1.2.2) can be used to interface to subprograms written in other languages.
- Pragma LIST is supported but has the intended effect only if the command line option -La was supplied for compilation, and the listing generated was not due to the presence of errors and/or warnings.
- Tartan compilers currently optimize both the time and space aspects based on what is best in the local context. Future releases of the compiler will have option switches to decrease the level of sophistication of the optimizations. Because it is generally very difficult to establish global time and space tradeoffs, pragma OPTIMIZE cannot be effectively supported in the form suggested in the LRM.
- Pragma PACK is fully supported.
- Pragma PAGE is supported but has the intended effect only if the command line option -La was supplied for compilation, and the listing generated was not due to the presence of errors and/or warnings.
- Pragma PRIORITY is fully supported.
- Pragma SUPPRESS is fully supported as required by Ada LRM 11.7.
- Future releases of the compiler will support the following pragmas: MEMORY_SIZE, SHARED, STORAGE_UNIT and SYSTEM_NAME.

A warning message will be issued if an unsupported pragma is supplied.

5.1.2. Implementation-Defined Pragmas
Implementation-defined pragmas provided by Tartan are described in the following sections.
5.1.2.1. Pragma LINKAGE_NAME

The pragma LINKAGE_NAME associates an Ada entity with a string that is meaningful externally; e.g., to a linkage editor. It takes the form

\begin{equation}
\text{pragma LINKAGE_NAME (Ada-simple-name, string-constant)}
\end{equation}

The Ada-simple-name must be the name of an Ada entity declared in a package specification. This entity must be one that has a runtime representation; e.g., a subprogram, exception or object. It may not be a named number or string constant. The pragma must appear after the declaration of the entity in the same package specification.

The effect of the pragma is to cause the string-constant to be used in the generated assembly code as an external name for the associated Ada entity. It is the responsibility of the user to guarantee that this string constant is meaningful to the linkage editor and that no illegal linkname clashes arise.

5.1.2.2. Pragma FOREIGN_BODY

A subprogram written in another language can be called from an Ada program. Pragma FOREIGN_BODY is used to indicate that the body for a non-generic top-level package specification is provided in the form of an object module. The bodies for several subprograms may be contained in one object module.

Use of the pragma FOREIGN_BODY dictates that all subprograms, exceptions and objects in the package are provided by means of a foreign object module. In order to successfully link a program including a foreign body, the object module for that body must be provided to the library using the \texttt{alib foreign} command described in Section 4.7.

The pragma is of the form:

\begin{equation}
\text{pragma FOREIGN_BODY (language_name [, elaboration_routine_name])}
\end{equation}

The parameter language_name is a string intended to allow the compiler to identify the calling convention used by the foreign module (but this functionality is not yet in operation). Currently, the programmer must ensure that the calling convention and data representation of the foreign body procedures are compatible with those used by the Tartan Ada compiler. Subprograms called by tasks should be reentrant.

The optional elaboration_routine_name string argument provides a means to initialize the package. The routine specified as the elaboration_routine_name, which will be called for the elaboration of this package body, must be a global routine in the object module provided by the user.

A specification that uses this pragma may contain only subprogram declarations, object declarations that use an unconstrained type mark, and number declarations. Pragmas may also appear in the package. The type mark for an object cannot be a task type, and the object declaration must not have an initial value expression. The pragma must be given prior to any declarations within the package specification. If the pragma is not located before the first declaration, or any restriction on the declarations is violated, the pragma is ignored and a warning is generated.

The foreign body is entirely responsible for initializing objects declared in a package utilizing pragma FOREIGN_BODY. In particular, the user should be aware that the implicit initializations described in LRM 3.2.1 are not done by the compiler. (These implicit initializations are associated with objects of access types, certain record types and composite types containing components of the preceding kinds of types.)

Pragma LINKAGE_NAME should be used for all declarations in the package, including any declarations in a nested package specification to be sure that there are no conflicting link names. If pragma LINKAGE_NAME is not used, the cross-reference qualifier, -x, (see Section 3.2) should be used when invoking the compiler and the resulting cross-reference table of linknames inspected to identify the linknames assigned by the compiler and determine that there are no conflicting linknames (see also Section 3.5).

In the following example, we want to call a function \texttt{plmn} which computes polynomials and is written in C.
package MATH_FUNCS is
  pragma FOREIGN_BODY ("C");
function POLYNOMIAL (X:INTEGER) return INTEGER;
  -- Ada spec matching the C routine
pragma LINKAGE_NAME (POLYNOMIAL, "plmn");
  -- Force Compiler to use name "plmn" when referring to this
  -- function
end MATH_FUNCS;

with MATH_FUNCS; use MATH_FUNCS
procedure MAIN is
  X:INTEGER := POLYNOMIAL(10);
  -- Will generate a call to "plmn"
    begin ...
end MAIN;

To compile, link and run the above program, you do the following steps:

1. Compile MATH_FUNCS
2. Compile MAIN
3. Obtain an object module (e.g. math.o) containing the compiled code for plmn.
4. Issue the command
   alib foreign math_funcs math.o
5. Issue the command
   alib link main

Without Step 4, an attempt to link will produce an error message informing you of a missing package body for MATH_FUNCS.

Using an Ada body from another Ada program library. The user may compile a body written in Ada for a specification into the library, regardless of the language specified in the pragma contained in the specification. This capability is useful for rapid prototyping, where an Ada package may serve to provide a simulated response for the functionality that a foreign body may eventually produce. It also allows the user to replace a foreign body with an Ada body without recompiling the specification.

The user can either compile an Ada body into the library, or use the command alib foreign (see Section 4.7) to use an Ada body from another library. The Ada body from another library must have been compiled under an identical specification. The pragma LINKAGE_NAME must have been applied to all entities declared in the specification. The only way to specify the linkname for the elaboration routine of an Ada body is with the pragma FOREIGN_BODY.

Using Calls to the Operating System. In some cases, the foreign code is actually supplied by the operating system (in the case of system calls) or by runtime libraries for other programming languages such as C. Such calls may be made using a dummy procedure to supply a file specification to the alib foreign command. You need a dummy .o file which may be obtained in a number of ways. One way is to compile the procedure

procedure DUMMY is
  begin
    null;
  end;

Then, use the library command

alib foreign pkg dummy.o

where pkg is the name of the package that contains the pragma LINKAGE_NAME for the operating system call.

For example to use the SunOS system call _sbrk in the program TEST:
Package MEMORY is
  pragma FOREIGN_BODY ("ASM");
  procedure GET_VIRTUAL_MEMORY (MEM: INTEGER);
  pragma LINKAGE_NAME (GET_VIRTUAL_MEMORY, "_sbrk");
end MEMORY;

with MEMORY:
procedure TEST is
  ...
begin
  GET_VIRTUAL_MEMORY (MEM);
  ...
end TEST;

Obtain the file dummy.o. Then use
  alib foreign memory dummy.o
to include the body for the system call in the library.

5.2. IMPLEMENTATION-DEPENDENT ATTRIBUTES

No implementation-dependent attributes are currently supported.

5.3. SPECIFICATION OF THE PACKAGE SYSTEM

The parameter values specified for the SUN in package system [LRM 13.7.1 and Appendix C] are:

package SYSTEM is
  type ADDRESS is new INTEGER;
  type NAME is (MC68000);
  SYSTEM_NAME : constant NAME := MC68000;
  STORAGE_UNIT : constant := 8;
  MEMORY_SIZE : constant := 1_000_000;
  MAX_INT : constant := 2_147_483_647;
  MIN_INT : constant := -MAX_INT - 1;
  MAX_DIGITS : constant := 15;
  MAX_MANTISSA : constant := 32;
  FINITE_DELTA : constant := 2*1.0e-31;
  TICK : constant := 0.01667;
  subtype PRIORITY is INTEGER range 10 .. 200;
  DEFAULT_PRIORITY : constant PRIORITY := PRIORITY'FIRST;
  RUNTIME_ERROR : exception;
end SYSTEM;

5.4. RESTRICTIONS ON REPRESENTATION CLAUSES

The following sections explain the basic restrictions for representation specifications followed by additional restrictions applying to specific kinds of clauses.

5.4.1. Basic Restriction

The basic restriction on representation specifications [LRM 13.1] that they may be given only for types declared in terms of a type definition, excluding a generic_type_definition (LRM 12.1) and a private_type_definition (LRM 7.4). Any representation clause in violation of these rules is not obeyed by the compiler; a diagnostic message is issued.

Further restrictions are explained in the following sections. Any representation clauses violating those restrictions are not obeyed but cause a diagnostic message to be issued.
5.4.2. Length Clauses

Length clauses [LRM 13.2] are, in general, supported. For details, refer to the following sections.

5.4.2.1. Size Specifications for Types

The rules and restrictions for size specifications applied to types of various classes are described below.

The following principle rules apply:

1. The size is specified in bits and must be given by a static expression.

2. The specified size is taken as a mandate to store objects of the type in the given size wherever feasible. No attempt is made to store values of the type in a smaller size, even if possible. The following rules apply with regard to feasibility:

   • An object that is not a component of a composite object is allocated with a size and alignment that is referable on the target machine; that is, no attempt is made to create objects of non-referable size on the stack. If such stack compression is desired, it can be achieved by the user by combining multiple stack variables in a composite object; for example

     ```
     type My_Enum is (A,B);
     for My_enum'size use 1;
     V,W: My_enum; -- will occupy two storage units on the stack
     -- (if allocated at all)
     ```

   • A formal parameter of the type is sized according to calling conventions rather than size specifications of the type. Appropriate size conversions upon parameter passing take place automatically and are transparent to the user.

   • Adjacent bits to an object that is a component of a composite object, but whose size is non-referable, may be affected by assignments to the object, unless these bits are occupied by other components of the composite object; that is, whenever possible, a component of non-referable size is made referable.

In all cases, the compiler generates correct code for all operations on objects of the type, even if they are stored with differing representational size in different contexts.

Note: A size specification cannot be used to force a certain size in value operations of the type; for example

```
type my_int is range 0..65535;
for my_int'size use 16; -- o.k.
A,B: my_int;
...A + B... -- this operation will generally be executed on 32-bit values
```
type MY_INT is range 0..2**15-1;
for MY_INT'SIZE use 16; -- (1)
subtype SMALL_MY_INT is MY_INT range 0..255;
type R is record
   X: SMALL_MY_INT;
   ... end record;

the component R.X will occupy 16 bits. In the absence of the length clause at (1), R.X may be represented in 8 bits.

For the following type classes, the size specification must coincide with the default size chosen by the compiler for the type:

- access types
- floating-point types
- task types

No useful effect can be achieved by using size specifications for these types.

5.4.2.2. Size Specification for Scalar Types

The specified size must accommodate all possible values of the type including the value 0 (even if 0 is not in the range of the values of the type). For numeric types with negative values the number of bits must account for the sign bit. No skewing of the representation is attempted. Thus

type my_int is range 100..101;
requires at least 7 bits, although it has only two values, while

type my_int is range -101..-100;
requires 8 bits to account for the sign bit.

A size specification for a real type does not affect the accuracy of operations on the type. Such influence should be exerted via the accuracy_definition of the type (LRM 3.5.7, 3.5.9).

A size specification for a scalar type may not specify a size larger than the largest operation size supported by the target architecture for the respective class of values of the type.

5.4.2.3. Size Specification for Array Types

A size specification for an array type must be large enough to accommodate all components of the array under the densest packing strategy explained below in adherence to any alignment constraints on the component type (see Section 5.4.7).

The size of the component type cannot be influenced by a length clause for an array. Within the limits of representing all possible values of the component subtype (but not necessarily of its type), the representation of components may, however, be reduced to the minimum number of bits, unless the component type carries a size specification.

If there is a size specification for the component type, but not for the array type, the component size is rounded up to a referable size, unless pragma PACK is given. This applies even to boolean types or other types that require only a single bit for the representation of all values.

5.4.2.4. Size Specification for Record Types

A size specification for a record type does not influence the default type mapping of a record type. The size must be at least as large as the number of bits determined by type mapping. Influence over packing of components can be exerted by means of (partial) record representation clauses or by Pragma PACK.

Neither the size of component types, nor the representation of component subtypes can be influenced by a length clause for a record.
The only implementation-dependent components allocated by Tartan Ada in records contain dope information for arrays whose bounds depend on discriminants of the record or contain relative offsets of components within a record layout for record components of dynamic size. These implementation-dependent components cannot be named or sized by the user.

A size specification cannot be applied to a record type with components of dynamically determined size.

Note: Size specifications for records can be used only to widen the representation accomplished by padding at the beginning or end of the record. Any narrowing of the representation over default type mapping must be accomplished by representation clauses or pragma PACK.

5.4.2.5. Specification of Collection Sizes

The specification of a collection size causes the collection to be allocated with the specified size. It is expressed in storage units and need not be static: refer to package SYSTEM for the meaning of storage units.

Any attempt to allocate more objects than the collection can hold causes a STORAGE_ERROR exception to be raised. Dynamically sized records or arrays may carry hidden administrative storage requirements that must be accounted for as part of the collection size. Moreover, alignment constraints on the type of the allocated objects may make it impossible to use all memory locations of the allocated collection. Furthermore, some administrative overhead for the allocator must be taken into account by the user (currently 1 word per allocated object).

In the absence of a specification of a collection size, the collection is extended automatically if more objects are allocated than possible in the collection originally allocated with the compiler-established default size. In this case, STORAGE_ERROR is raised only when the available target memory is exhausted. If a collection size of zero is specified, no access collection is allocated.

5.4.2.6. Specification of Task Activation Size

The specification of a task activation size causes the task activation to be allocated with the specified size. It is expressed in storage units: refer to package SYSTEM for the meaning of storage units.

Any attempt to exceed the activation size during execution causes a STORAGE_ERROR exception to be raised. Unlike collections, there is generally no extension of task activations.

5.4.2.7. Specification of 'SMALL'

Only powers of 2 are allowed for 'SMALL'.

The length of the representation may be affected by this specification. If a size specification is also given for the type, the size specification takes precedence; the specification of 'SMALL' must then be accommodatable within the specified size.

5.4.3. Enumeration Representation Clauses

For enumeration representation clauses [LRM 13.3], the following restrictions apply:

- The internal codes specified for the literals of the enumeration type may be any integer value between INTEGER'FIRST and INTEGER'LAST. It is strongly advised not to provide a representation clause that merely duplicates the default mapping of enumeration types, which assigns consecutive numbers in ascending order starting with 0, since unnecessary runtime cost is incurred by such duplication. It should be noted that the use of attributes on enumeration types with user-specified encodings is costly at run time.

- Array types, whose index type is an enumeration type with non-contiguous value encodings, consist of a contiguous sequence of components. Indexing into the array involves a runtime translation of the index value into the corresponding position value of the enumeration type.
5.4.4. Record Representation Clauses

The alignment clause of record representation clauses [LRM 13.4] is observed. The specified expression must yield a target-dependent value.

Static objects may be aligned at powers of 2 up to a page boundary. The specified alignment becomes the minimum alignment of the record type, unless the minimum alignment of the record forced by the component allocation and the minimum alignment requirements of the components is already more stringent than the specified alignment.

The component clauses of record representation clauses are allowed only for components and discriminants of statically determinable size. Not all components need to be present. Component clauses for components of variant parts are allowed only if the size of the record type is statically determinable for every variant.

The size specified for each component must be sufficient to allocate all possible values of the component subtype (but not necessarily the component type). The location specified must be compatible with any alignment constraints of the component type; an alignment constraint on a component type may cause an implicit alignment constraint on the record type itself.

If some, but not all, discriminants and components of a record type are described by a component clause, then the discriminants and components without component clauses are allocated after those with component clauses; no attempt is made to utilize gaps left by the user-provided allocation.

5.4.5. Address clauses

Address clauses [LRM 13.5] are supported with the following restrictions:

- When applied to an object, an address clause becomes a linker directive to allocate the object at the given address. For any object not declared immediately within a top-level library package, the address clause is meaningless. Address clauses applied to local packages are not supported by Tartan Ada. Address clauses applied to library packages are prohibited by the syntax; therefore, an address clause can be applied only to a package if it is a body stub.
- Address clauses applied to subprograms and tasks are implemented according to the LRM rules. When applied to an entry, the specified value identifies an interrupt in a manner customary for the target. Immediately after a task is created, a runtime call is made for each of its entries having an address clause, establishing the proper binding between the entry and the interrupt.
- Specified addresses must be constants.

5.4.6.Pragma PACK

Pragma PACK [LRM 13.1] is supported. For details, refer to the following sections.

5.4.6.1. Pragma PACK for Arrays

If pragma PACK is applied to an array, the densest possible representation is chosen. For details of packing, refer to the explanation of size specifications for arrays (Section 5.4.2.3).

If, in addition, a length clause is applied to

1. the array type, the pragma has no effect, since such a length clause already uniquely determines the array packing method.
2. the component type, the array is packed densely, observing the component's length clause. Note that the component length clause may have the effect of preventing the compiler from packing as densely as would be the default if pragma PACK is applied where there was no length clause given for the component type.
5.4.6.2. The Predefined Type String

Package STANDARD appliesPragma PACK to the type string. However, when applied to character arrays, this pragma cannot be used to achieve denser packing than is the default for the target: 1 character per 8-bit word.

5.4.6.3. Pragma PACK for Records

If pragma PACK is applied to a record, the densest possible representation is chosen that is compatible with the sizes and alignment constraints of the individual component types. Pragma PACK has an effect only if the sizes of some component types are specified explicitly by size specifications and are of non-referable nature. In the absence of pragma PACK, such components generally consume a referable amount of space.

It should be noted that default type mapping for records maps components of boolean or other types that require only a single bit to a single bit in the record layout, if there are multiple such components in a record. Otherwise, it allocates a referable amount of storage to the component.

If pragma PACK is applied to a record for which a record representation clause has been given detailing the allocation of some but not all components, the pragma PACK affects only the components whose allocation has not been detailed. Moreover, the strategy of not utilizing gaps between explicitly allocated components still applies.

5.4.7. Minimal Alignment for Types

Certain alignment properties of values of certain types are enforced by the type mapping rules. Any representation specification that cannot be satisfied within these constraints is not obeyed by the compiler and is appropriately diagnosed.

Alignment constraints are caused by properties of the target architecture, most notably by the capability to extract non-aligned component values from composite values in a reasonably efficient manner. Typically, restrictions exist that make extraction of values that cross certain address boundaries very expensive, especially in contexts involving array indexing. Permitting data layouts that require such complicated extractions may impact code quality on a broader scale than merely in the local context of such extractions.

Instead of describing the precise algorithm of establishing the minimal alignment of types, we provide the general rule that is being enforced by the alignment rules:

- No object of scalar type including components or subcomponents of a composite type, may span a target-dependent address boundary that would mandate an extraction of the object's value to be performed by two or more extractions.

5.5. IMPLEMENTATION-GENERATED COMPONENTS IN RECORDS

The only implementation-dependent components allocated by Tartan Ada in records contain dope information for arrays whose bounds depend on discriminants of the record. These components cannot be named by the user.

5.6. INTERPRETATION OF EXPRESSIONS APPEARING IN ADDRESS CLAUSES

Section 13.5.1 of the Ada Language Reference Manual describes a syntax for associating interrupts with task entries. Tartan Ada implements the address clause

for TOENTRY use at intID;

by associating the interrupt specified by intID with the toentry entry of the task containing this address clause. The interpretation of intID is both machine and compiler dependent.
5.7. RESTRICTIONS ON UNCHECKED CONVERSIONS

Tartan supports UNCHECKED\_CONVERSION with a restriction that requires the sizes of both source and target types to be known at compile time. The sizes need not be the same. If the value in the source is wider than that in the target, the source value will be truncated. If narrower, it will be zero-extended. Calls on instantiations of UNCHECKED\_CONVERSION are made inline automatically.

5.8. IMPLEMENTATION-DEPENDENT ASPECTS OF INPUT-OUTPUT PACKAGES

Tartan Ada supports all predefined input/output packages [LRM Chapter 14] with the exception of LOW\_LEVEL\_IO (which is planned for a future release).

SEQUENTIAL\_IO and DIRECT\_IO may not be instantiated on types whose representation size is greater than 32255 bytes. Any attempt to read or write values of such types raises USE\_ERROR.

SEQUENTIAL\_IO and DIRECT\_IO may not be instantiated on unconstrained array types, nor on record record types with discriminants without default values.

An attempt to delete an external file while more than one internal file refers to this external file raises USE\_ERROR.

When an external file is referenced by more than one internal file, an attempt to reset one of those internal files to OUT\_FILE raises USE\_ERROR.

An attempt to create a file with FILE\_MODE IN\_FILE raises USE\_ERROR.

Since the implementation of the input-output packages uses buffers, output to one file cannot necessarily be read immediately from another file associated with the same external file.

The FORM parameter of file management subprograms is ignored.

An attempt to read a non-existent data record through the operations of SEQUENTIAL\_IO or DIRECT\_IO raises DATA\_ERROR except that END\_ERROR is raised when reading beyond the end of file.

If a SunOS system call returns an error number that cannot be mapped onto a predefined Ada exception, the exception DEVICE\_ERROR is raised.

5.9. OTHER IMPLEMENTATION CHARACTERISTICS

The following information is supplied in addition to that required by Appendix F to MIL-STD-1815A.

5.9.1. Definition of a Main Program

Any Ada library subprogram unit may be designated the main program for purposes of linking (using the a1ib command) provided that the subprogram has no parameters.

Tasks initiated in imported library units follow the same rules for termination as other tasks [described in LRM 9.4 (6-10)]. Specifically, these tasks are not terminated simply because the main program has terminated. Terminate alternatives in selective wait statements in library tasks are therefore strongly recommended.

5.9.2. Implementation of Generic Units

All instantiations of generic units, except the predefined generic UNCHECKED\_CONVERSION and UNCHECKED\_DEALLOCATION subprograms, are implemented by code duplications. No attempt at sharing code by multiple instantiations is made in this release of Tartan Ada. (Code sharing will be implemented in a later release.)

Tartan Ada enforces the restriction that the body of a generic unit must be compiled before the unit can be instantiated. It does not impose the restriction that the specification and body of a generic unit must be provided as part of the same compilation. A recompilation of the body of a generic unit will obsolete any units that instantiated this generic unit.
5.9.3. Implementation-Defined Characteristics in Package STANDARD

The implementation-dependent characteristics for SUN in package STANDARD [Annex C] are:

```
5.9.4. Attributes of Type Duration

The type DURATION is defined with the following characteristics:

DURATION' DELTA is 0.0001 sec
DURATION' SMALL is 6.103516E-5 sec
DURATION' FIRST is -86400.0 sec
DURATION' LAST is 86400.0 sec
```

5.9.5. Values of Integer Attributes

Tartan Ada supports the predefined integer types INTEGER, SHORT_INTEGER and BYTE_INTEGER. The range bounds of the predefined type INTEGER are:

```
INTEGER' FIRST = -2**31
INTEGER' LAST = 2**31 - 1
```

```
SHORT_INTEGER' FIRST = -2**15
SHORT_INTEGER' LAST = 2**15 - 1
```

```
BYTE_INTEGER' FIRST = -128
BYTE_INTEGER' LAST = 127
```

The range bounds for subtypes declared in package TEXT IO are:

```
COUNT' FIRST = 0
COUNT' LAST = INTEGER' LAST - 1
```

```
POSITIVE_COUNT' FIRST = 1
POSITIVE_COUNT' LAST = INTEGER' LAST - 1
```

```
FIELD' FIRST = 0
FIELD' LAST = 20
```

The range bounds for subtypes declared in packages DIRECT IO are:

```
COUNT' FIRST = 0
COUNT' LAST = INTEGER' LAST
```

```
POSITIVE_COUNT' FIRST = 1
POSITIVE_COUNT' LAST = COUNT' LAST
```
5.9.6. Values of Floating-Point Attributes

Tartan Ada supports the predefined floating-point types `FLOAT` and `LONG_FLOAT`.

</table>
Certain tests in the ACVC make use of implementation-dependent values, such as the maximum length of an input line and invalid file names. A test that makes use of such values is identified by the extension .TST in its file name. Actual values to be substituted are represented by names that begin with a dollar sign. A value must be substituted for each of these names before the test is run. The values used for this validation are given below. The use of the '*' operator signifies a multiplication of the following character, and the use of the '&' character signifies concatenation of the preceding and following strings. The values within single or double quotation marks are to highlight character or string values:

<table>

</tr>
</tbody>
</table>
Name and Meaning

$BIG_ID4
An identifier the size of the maximum input line length which is identical to $BIG_ID3 except for a character near the middle.

$BIG_INT_LIT
An integer literal of value 298 with enough leading zeroes so that it is the size of the maximum line length.

$BIG_REAL_LIT
A universal real literal of value 690.0 with enough leading zeroes to be the size of the maximum line length.

$BIG_STRING1
A string literal which when catenated with BIG_STRING2 yields the image of BIG_ID1.

$BIG_STRING2
A string literal which when catenated to the end of BIG_STRING1 yields the image of BIG_ID1.

SBLANKS
A sequence of blanks twenty characters less than the size of the maximum line length.

$COUNT_LAST
A universal integer literal whose value is TEXTIO.COUNT'LAST.

$DEFAULT_MEM_SIZE
An integer literal whose value is SYSTEM.MEMORY_SIZE.

$DEFAULT_STOR_UNIT
An integer literal whose value is SYSTEM.STORAGE_UNIT.

</tbody>
</table>
Name and Meaning

$\text{MAX}_\text{LEN}_\text{INT}_\text{BASED}_\text{LITERAL}$
A universal integer based literal whose value is $2\#11#$ with enough leading zeroes in the mantissa to be $\text{MAX}_\text{IN}_\text{LEN}$ long.

$\text{MAX}_\text{LEN}_\text{REAL}_\text{BASED}_\text{LITERAL}$
A universal real based literal whose value is $16:\text{F.E:}$ with enough leading zeroes in the mantissa to be $\text{MAX}_\text{IN}_\text{LEN}$ long.

$\text{MAX}_\text{STRING}_\text{LITERAL}$
A string literal of size $\text{MAX}_\text{IN}_\text{LEN}$, including the quote characters.

$\text{MIN}_\text{INT}$
A universal integer literal whose value is $\text{SYSTEM.MIN}_\text{INT}$.

$\text{MIN}_\text{TASK}_\text{SIZE}$
An integer literal whose value is the number of bits required to hold a task object which has no entries, no declarations, and "NULL;" as the only statement in its body.

$\text{NAME}$
A name of a predefined numeric type other than $\text{FLOAT}$, $\text{INTEGER}$, $\text{SHORT}_\text{FLOAT}$, $\text{SHORT}_\text{INTEGER}$, $\text{LONG}_\text{FLOAT}$, or $\text{LONG}_\text{INTEGER}$.

$\text{NAME}_\text{LIST}$
A list of enumeration literals in the type $\text{SYSTEM.NAME}$, separated by commas.

$\text{NEG}_\text{BASED}_\text{INT}$
A based integer literal whose highest order nonzero bit falls in the sign bit position of the representation for $\text{SYSTEM.MAX}_\text{INT}$.

Some tests are withdrawn from the ACVC because they do not conform to the Ada Standard. The following 43 tests had been withdrawn at the time of validation testing for the reasons indicated. A reference of the form AI-ddddd is to an Ada Commentary.

a. E28005C  This test expects that the string "-- TOP OF PAGE. -- 63" of line 204 will appear at the top of the listing page due to a pragma PAGE in line 203; but line 203 contains text that follows the pragma, and it is this that must appear at the top of the page.

b. A39005G  This test unreasonably expects a component clause to pack an array component into a minimum size (line 30).

c. B97102E  This test contains an unintended illegality: a select statement contains a null statement at the place of a selective wait alternative (line 31).

d. BC3009B  This test wrongly expects that circular instantiations will be detected in several compilation units even though none of the units is illegal with respect to the units it depends on; by AI-00256, the illegality need not be detected until execution is attempted (line 95).

e. CD2A62D  This test wrongly requires that an array object's size be no greater than 10 although its subtype's size was specified to be 40 (line 137).

f. CD2A63A..D, CD2A66A..D, CD2A73A..D, CD2A76A..D [16 tests]  These tests wrongly attempt to check the size of objects of a derived type (for which a 'SIZE length clause is given) by passing them to a derived subprogram (which implicitly converts them to the parent type (Ada standard 3.4:14)). Additionally, they use the 'SIZE length clause and attribute whose interpretation is considered problematic by the WG9 ARG.

g. CD2A81G, CD2A83G, CD2A84N & M, CD50110 [5 tests]  These tests assume that dependent tasks will terminate while the main program executes a loop that simply tests for task termination; this is not the case, and the main program may loop indefinitely (lines 74, 85, 86 & 96, 86 & 96, and 58, resp.).
WITHDRAWN TESTS

h. CD2B15C & CD7205C These tests expect that a 'STORAGE_SIZE length clause provides precise control over the number of designated objects in a collection; the Ada standard 13.2:15 allows that such control must not be expected.

i. CD2D11B This test gives a SMALL representation clause for a derived fixed-point type (at line 30) that defines a set of model numbers that are not necessarily represented in the parent type; by Commentary AI-00099, all model numbers of a derived fixed-point type must be representable values of the parent type.

j. CD5007B This test wrongly expects an implicitly declared subprogram to be at the address that is specified for an unrelated subprogram (line 303).

k. ED7004B, ED7005C & D, ED7006C & D [5 tests] These tests check various aspects of the use of the three SYSTEM pragmas; the AVO withdraws these tests as being inappropriate for validation.

l. CD7105A This test requires that successive calls to CALENDAR.CLOCK change by at least SYSTEM.TICK; however, by Commentary AI-00201, it is only the expected frequency of change that must be at least SYSTEM.TICK--particular instances of change may be less (line 29).

m. CD7203B, & CD7204B These tests use the 'SIZE length clause and attribute, whose interpretation is considered problematic by the WG9 ARG.

n. CD7205D This test checks an invalid test objective: it treats the specification of storage to be reserved for a task's activation as though it were like the specification of storage for a collection.

o. CE21071 This test requires that objects of two similar scalar types be distinguished when read from a file--DATA_ERROR is expected to be raised by an attempt to read one object as of the other type. However, it is not clear exactly how the Ada standard 14.2.4:4 is to be interpreted; thus, this test objective is not considered valid. (line 90)

p. CE3111C This test requires certain behavior, when two files are associated with the same external file, that is not required by the Ada standard.

q. CE3301A This test contains several calls to END_OF_LINE & END_OF_PAGE that have no parameter: these calls were intended to specify a file, not to refer to STANDARD_INPUT (lines 103, 107, 118, 132, & 136).
This test requires that a text file's column number be set to COUNT-LAST in order to check that LAYOUT_ERROR is raised by a subsequent PUT operation. But the former operation will generally raise an exception due to a lack of available disk space, and the test would thus encumber validation testing.
APPENDIX E

COMPILER AND LINKER OPTIONS

This appendix contains information of the compiler and linker options used in this validation.
NAME
tada - Tartan Ada Compiler

SYNOPSIS
tada [option ...] file [option ...]

DESCRIPTION
tada is the Tartan Ada Compiler. tada compiles a source file, sequentially processing all compilation units. Upon successful compilation of a unit, the ada program library ada.db which must reside in the working directory is updated and one or more separate compilation files and/or object files are generated. (Refer to alib(1) for instructions on how to obtain an initial ada.db).

At least one argument must be a source file name. Any number of options, each beginning with a hyphen, may precede or follow it. Later options override earlier options. The following options are recognized:

-Fh Select hardware floating point support. This is the default.

-Fs Select Sun software floating point support.

-La Generate a listing, even if no errors were found. The default is to generate a listing only if an error is found.

-Ln Never generate a listing. The default is to generate a listing only if an error is found.

-i Cause compiler to omit data segments with the text of enumeration literals. This text is normally produced for exported enumeration types in order to support the 'IMAGE attribute. You should use -i only when you can guarantee that no unit that will import the enumeration type will use 'IMAGE. However, if you are compiling a unit with an enumeration type that is not visible to other compilation units, this option is not needed. The compiler can recognize when 'IMAGE is not used and will not generate the supporting strings.

-a Causes the compiler to retain generated assembly code in the user's directory.
COMPILER AND LINKER OPTIONS

-Opn Control the level of optimization performed by the compiler, requested by n. The optimization levels available are:

n=0 Minimum - Performs context determination, constant folding, algebraic manipulation, and short circuit analysis.

n=1 Low - Performs level 0 optimizations plus common subexpression elimination and equivalence propagation within basic blocks. It also optimizes evaluation order.

n=2 Space - Performs level 1 optimizations plus flow analysis which is used for common subexpression elimination and equivalence propagation across basic blocks. It also performs invariant expression hoisting, dead code elimination, and assignment killing. Level 2 also performs lifetime analysis which is used to improve register allocation. It also performs inline expansion of subprogram calls indicated by Pragma Inline which appears in the same compilation unit.

n=3 Time - Performs level 2 optimizations plus inline expansion of subprogram calls which the optimizer decides are profitable to expand (from an execution time perspective). Other optimizations which improve execution time at a cost to image size are performed only at this level.

-pc68000  Generate code for the 68000 instruction set.

-pc68010  Generate code for the 68010 instruction set.

-pc68020  Generate code for the 68020 instruction set. This is the default.

-v Printout compiler phase names. The compiler will print out a short description of each compilation phase in progress.

-S[ACDEILORSZ] Cause the compiler to omit extra code to perform various checks at run time. The action of this option is equivalent to applying a pragma SUPPRESS
to the entire source program. Supplying the -S option significantly decreases the size and execution time of the compiled code.

Suppress the given set of checks:

A  ACCESS_CHECK
C  CONSTRAINT_CHECK
D  DISCRIMINANT_CHECK
E  ELABORATION_CHECK
I  INDEX_CHECK
L  LENGTH_CHECK
O  OVERFLOW_CHECK
R  RANGE_CHECK
S  STORAGE_CHECK
Z  "ZERO"DIVISION_CHECK

Examples:

-SOZ  Suppress OVERFLOW and DIVISION.
-S   Suppress ALL
-SC  Suppress CONSTRAINT_ERROR, equiv. to -SADILR

-x  Cause the compiler to generate a cross reference file containing entries of the form 'Ada-name=>linkname at line'. This option will allow users to find the linkname generated for the given Ada-name, and use linkname to set breakpoints in debuggers. The file will have the extension .xrf.

FILES

source
Any legal Unix file name is acceptable as Ada source to tada.

source.lst
Listing file containing source interspersed with error messages. At most one .lst file is generated for a single source file.

For the remaining files, one file is generated for each compilation unit (cu); therefore, compiling a single source file with multiple compilation units may result in more than one of each of these files. Their names are derived from the Ada name of the compilation unit rather than from the source file.

cuname.xrf  Cross reference listing
cuname.di  Separate compilation file (spec)
cuname.bod  Separate compilation file (generic body)
cuname.con  Separate compilation file (subunit context)
cuname.map  File containing a memory allocation listing (map)
cuname.stb  File of symbol definitions for all global symbols in the image.
cuname.s    Assembly code file
cuname.ss   Assembly code file
cuname.o    Object file
cuname.so   Object file

Other files:

  tada       Tartan ada compiler
  ada.db     User library database

Some temporary files are also created. For an explanation of those file, see

DIAGNOSTICS

BUGS
  Please refer to the Release Notes distributed with your compi-
  laler.
NAME
alib - the Tartan Ada Program Librarian

SYNOPSIS
alib subcommand [option ...] [argument ...] [option ...]

DESCRIPTION
The Tartan Ada Program Librarian alib implements the Ada Language requirement for separate compilation and dependency control.

The program library directory holds all necessary compilation units, including packages that are part of the application under development and any standard packages such as those for I/O. It also holds a library administration file which is a database file, ada.db, whose contents are managed by the Tartan Ada librarian, alib, and the tada command. The program library in effect during a compilation may be specified explicitly connecting to the directory containing the library administration file name. The alib command invokes the Ada Program Librarian to:

Create an Ada library
Delete an entire library
Delete unit(s) from an Ada library
Check the closure of a unit in the library
Provide useful information about a unit in the library
Insert a non-Ada object into the library as the body of a package.
Link an executable image

Each operation is requested through a subcommand. Most commands take an Ada-name as an argument. This is the identifier used in the compilation unit declaration. There is no required correspondence between this identifier and the source file name. To allow subcommands to use regular expressions containing wildcard characters, the standard usage of "*" and "?" has been abandoned. The character "#" replaces "*" and "?" replaces "?" for all Ada-name regular expressions.
Names are simple Ada-names for library units and their bodies, and Ada-name pairs for subunits. A pair consists of: ancestor-name subunit-simple-name.

The following subcommands are available.

mklib creates an initialized Ada library database file, ada.db, and places it in a directory that has been created to hold the library database file and files required by the library, i.e., separate compilation and compiler-generated files. Standard system and Ada I/O packages are placed in the library directory and references to them are recorded in ada.db. The format of the mklib command is

`alib mklib [directory]`

where the argument directory specifies the name of the existing subdirectory in which the library is to be located and must be supplied only if the library directory is not the current directory.

rmlib deletes the entire library identified by the directory path supplied as an argument, including all compiler-generated files and the file ada.db. No wildcards may be used in the directory name. The format of the rmlib command is

`alib rmlib [option ...] directory`

where the argument directory specifies the name of the subdirectory in which the library is located.

The following option may be used with the rmlib command:

-`-log` causes a message to be written to stdout after each unit is deleted.

delete deletes the specified unit from the library. The format of the delete command is

`alib delete [option ...] Ada-name ...`

where each argument Ada-name specifies the name of a unit to be deleted.

The following options may be used with the delete command:

-`-b` deletes the body unit and any subunits emanating from this body. The Ada-name supplied as an argument must be a library unit name. All compiler-generated files are deleted with the unit. Compiler-generated
files do not include those created by the librarian with the link subcommand. This is the default if no option is supplied.

-s deletes the specification, body and all subunits that have this specification as an ancestor from the library. The Ada-name supplied as a argument must be a library unit name. All compiler-generated files are deleted with the unit.

-sub deletes the subunit named and all of its subunits, in a transitive manner. An Ada-name pair containing an ancestor-name and a subunit-simple-name is required.

-l causes a message to be written to stdout after the unit is deleted. This option may be used in combination with any other option.

closure checks the closure or full closure of the named units. Any errors associated with the closure are reported to stderr, and the partial ordering of the closure is sent to stdout. The format of the closure command is

    alib closure [option ...] Ada-name ...

where the argument Ada-name specifies the name of the unit whose closure is to be checked.

The following options may be used with the closure command:

-b checks closure only on the body unit named by the Ada-name argument. The Ada-name supplied as a argument must be a library unit name.

-s checks closure only on the specification unit named by the Ada-name argument. The Ada-name must be a library unit name. This is the default if no option is supplied.

-sub checks closure of a subunit which must be identified by two arguments, the name of the ancestor and the simple name of the subunit.

-full checks the full closure (linking closure) for the specification unit named by the Ada-name argument. The Ada-name must be a library unit name.

describe provides information about the unit. It lists name, type, time of compilation, state of residence (local or foreign), source and binary file specifications, first-
level dependencies (if any), and subunits (if any). The describe command is

```
alinb describe [option ...] Ada-name ...
```

where the argument Ada-name specifies the name of the unit to be described.

One of the following options may be used with the describe command:

- **-a** describes both the specification and body units for the specified library unit. The Ada-name supplied as a argument must be a library unit name. -a is a shorthand for -s -b and is the default if no option is supplied.

- **-A** describes all library units and subunits. No Ada-name should be specified.

- **-b** describes only the body unit for the specified library unit. The Ada-name supplied must be a library unit name. No information about bodies resulting from generic instantiations is given when the -b option is given. To get such information use -s or -a.

- **-s** describes only the specification unit for the specified library unit. The Ada-name supplied as a argument must be a library unit name.

- **-sub** describes the subunit. An Ada-name pair containing an ancestor-name and a subunit-simple-name is required.

**foreign** inserts a pointer to an object file into the library for a package whose specification contains a pragma FOREIGN_BODY. The format of the foreign command is

```
alinb foreign [option ...] Ada-name file
```

where the argument Ada-name specifies the name of the package containing the pragma FOREIGN_BODY. The argument file is the path-name of the object file.

The following option may be used with the foreign command:

- **-l** informs the librarian that the object file is an ar archive format file. The librarian will use this information by attempting to link this file last when a link operation is invoked.
```
-c  Copies the named file into the library's directory.
      (See bugs)

link checks that the unit has the legal form for a main unit, checks the full closure, finds all required object files, and invokes ld to link the appropriate object files and produce an executable file. The format of the link command is

    alib link [option ...] Ada-name [option ...]

where the argument Ada-name specifies the unit in the library to be made the main program.

The following options may be used with the link command:

- K  creates a shell script file that may be redirected to sh to cause the Ada program to be linked. The user assumes full responsibility for the consistency of the program when this script is run instead of using the alib link command.

- M  causes ld to produce a load map.

- o  file names the final output file from the loader

- t  invokes ld with the -t switch to provide a trace of the load command indicating what files are being loaded

SEE ALSO
    tada(1), The Tartan Ada Compiler

DIAGNOSTICS

BUGS
    alib delete -s # will delete all units in the library, as expected, and will also delete the file ada.db. It is a synonym for alib rmlib ..

    The -c switch for foreign is not implemented.

    Please refer to the Release Notes distributed with your compiler.
