A Prototype Construction Duration Estimating System (CODES) for Mid-Rise Building Construction

by
Ruofei Sun
Guruprasad N. Rao
Diego Echeverry
Simon Kim

This interim report describes the concepts that support the development of the prototype Construction Duration Estimating System (CODES) for mid-rise building construction. The prototype system: (1) breaks down the construction process into major activities, (2) sequences activities logically, and (3) estimates approximate activity durations of major construction activities. While the CODES prototype is limited to office and residential construction projects, through an enhancement of the user interface, project-specific features can be input to the prototype to modify its produced schedules. CODES is presently in its validation and testing phase.

FOREWORD

This study was conducted for the Directorate of Military Programs, Headquarters, U.S. Army Corps of Engineers (HQUSACE), under Project 4A162734AT41, "Military Facilities Engineering Technology"; Work Unit SA, Task AF0, "Construction Control Knowledge Schedule." The HQUSACE technical monitor was Mr. James Jones, CEMP-CP.

This research was performed by the Facility Systems Division (FS) of the U.S. Army Construction Engineering Research Laboratory (USACERL). The principal investigator was Dr. Diego Echeverry. Dr. Michael J. O'Connor is Chief, USACERL-FS. The USACERL technical editor was Mr. William J. Wolfe, Information Management Office.

COL Everett R. Thomas is Commander and Director of USACERL, and Dr. L.R. Shaffer is Technical Director.

A PROTOTYPE CONSTRUCTION DURATION ESTIMATING
SYSTEM (CODES) FOR MID-RISE BUILDING CONSTRUCTION

1 INTRODUCTION

Background

The actual duration of both military and civil works construction projects is often substantially
different from the estimates or schedules made prior to initiation of construction. In fiscal year (FY) 1988,
actual duration of military construction projects took an average of 17 percent longer than estimated.
Similarly, actual duration of civil construction projects averaged 19 percent longer than estimated.

More accurate estimates will require: (1) improved duration estimation and project schedule
generation prior to construction start, (2) enhanced schedule control during construction, and (3) a more
structured process of synthesizing the lessons learned in current or concluded projects, to benefit the
planning and control of future projects. This research focuses on the first of these actions, the
development of enhanced computer tools to support the construction duration estimation and project
schedule generation tasks.

Commercially available computer software provides some limited support to produce project
schedules; however, the actual schedule generation process is done manually. This manual process
includes: (1) activity identification, (2) activity logic determination, and (3) duration estimation.
Automated tools are needed to support these tasks.

Objectives

The objective of this phase of work was to develop a project-scheduling, knowledge-based prototype
system to estimate construction duration, specifically, to support activity identification and sequencing,
and activity duration estimation. The objectives of the concluding phase of this study will be to verify
and enhance the current working prototype, by: (1) conducting a hands-on review by engineering and
construction district personnel to obtain direct feedback from potential users, (2) incorporating the
recommendations made from that review and from the workshop conducted as a part of this study, and
(3) testing the prototype by applying the program to schedule records from selected building projects
performed in the past by Corps of Engineer districts.

Approach

The overall approach was to apply a Knowledge-Based Systems (KBS) technique that addresses the
generation of construction schedules. The work is to be accomplished in four phases—two described in
this interim report, and two to be the subject of a future report:

1. A literature survey was done, and skilled construction schedulers were interviewed to determine
how to: (a) break down a construction project into major activities, (b) estimate durations for those major
activities, and (c) establish a logical sequence to execute these major activities.

5
2. This acquired scheduling knowledge was represented in a prototype KBS, the Construction Duration Estimating System (CODES). An expert system developing tool called KnowledgePro\(^1\) was used to implement the system.

3. Contact will be made with potential CODES users. If feedback is received from them early during the tool development phase, the resulting product will be altered to better address their needs. A workshop was held with participants from different Corps of Engineers district offices to obtain their feedback.

4. Finally, field testing and validation is necessary to refine the tool to directly address user needs.

Scope

CODES focuses on the scheduling of mid-rise buildings of a residential/office nature. It is able to schedule projects with up to two underground floors, and assumes basic site work and very simple excavation. CODES's analysis is valid for typical floor sizes from 5000 to 20,000 sq ft\(^2\) per typical floor, and schedules only major activities.

The present report describes the concepts involved in the development of an initial working prototype of CODES. It does not describe a final product. A final product will be developed after the field testing and validation phases are concluded.

Mode of Technology Transfer

It is anticipated that CODES may become material for Huntsville division courses. Further technology transfer issues will be addressed during field testing in coordination with test sites.

---

\(^1\)KnowledgePro\(^{TM}\), IBM-PC version by Beverly and William Thompson (Knowledge Garden, Inc., Nassau, NY, 12123, 1988).  
\(^2\)1 sq ft = 0.093 m\(^2\)
2 PROCEDURE

Overview

CODES uses a KBS technique to develop enhanced computerized support for estimating construction duration (further sources for information on KBSs are listed in the “References” section at the end of this report). The application of a KBS technique incorporates the following steps: (1) survey of experienced construction schedulers to acquire knowledge of scheduling practices; (2) formalization and representation of the acquired knowledge in the selected software platform; and (3) validation and testing of the resulting prototype system. This report discusses the concepts supporting the development of the initial CODES prototype. Validation and field testing are in progress.

Knowledge Acquisition

Two main sources of expertise were addressed: publications and construction industry skilled schedulers. The interaction with industry schedulers was given priority. Construction schedulers from several construction firms were interviewed:

1. J.S. Abercici Construction Company Inc., St. Louis, MO
2. Duke Construction Company, Indianapolis, IN
3. Korte Construction Company, St. Louis, MO
5. Turner Construction Company, Chicago, IL.

At the time of the interviews, all interviewed schedulers had at least 10 years’ scheduling experience, mainly in building construction. This phase of the work was performed under a different work unit, and was reported separately.¹

To accommodate their tight schedules, construction schedulers were interviewed in two ways. Some discussions were based on schedules that the schedulers had produced in the past. The alternative approach was to select a mid-rise building (a 10-story residential building), for which complete design information was available, and to request the scheduler to guide the interviewer through the production of a schedule for the construction of this facility.

The goal of the knowledge acquisition effort was to develop a representation of the information obtained using the selected KBS platform that was suitable for translation into computer logic. This was accomplished by: (1) transforming an amorphous body of knowledge into a set of concepts, rules, and facts expressed in English language (Formalized Knowledge), and (2) representing a subset of this Formalized Knowledge in a syntax understandable by the KBS platform (KnowledgePro). The main concepts formalized and represented here are discussed in the sections below.

Activity Definition

Construction of today’s complex buildings includes a large number of activities or tasks. Schedule

approach is known as hierarchical planning. A major premise of this work, confirmed through the knowledge acquisition process is that, at the level of major activities, one can produce a reasonable duration estimate.

Focusing on major activities alone provides an overall project construction perspective (Figure 1). These major activities are collections of more detailed activities. Table 1 lists the abbreviated names used in CODES for these major activities.

Activity Logic

Essential to construction planning is the sequencing of activities to deliver the constructed facility. Activity sequencing logic in part depends on the way building components are physically related to each other. Activity sequencing also responds to other factors, like interaction among crews and equipment during construction time. For instance, one crew or type of equipment may damage the work performed by other crews. To prevent such damage, the operation of potentially damaging work is scheduled before the installation of more fragile work. For this reason, first floor finishes are performed last.

Table 2 shows the logic relations of the major activities considered here, specifies preceding activities, and also indicates the type of precedence relationship, which is either: (1) a start-to-start relationship (SS), or (2) a finish-to-start relationship (FS). A lag (time between activities) is associated with each precedence relationship, representing the time delay, in weeks, of each activity. For instance, the activity “Site & Foundation” is preceded by the activity “Mobilization” with a finish-to-start relationship and a lag of zero weeks. The prototype uses specific activity sequences, based on typical construction practice:

1. Site and foundation work is preceded by mobilization. (Contractor mobilization to the site is a prerequisite to start construction. The first construction activity is normally to prepare the site and then to proceed with foundation work.)

2. Frame erection is preceded by foundation work. (The frame is supported by the foundation.)

3. Roof frame erection is preceded by structural frame erection. (The roof frame is supported by the structural frame.)

4. Concrete deck placement is preceded by structural frame erection. (If the frame alternative is a steel frame, it is assumed that each floor slab consists of a composite metal-concrete deck. The placement of the different floor concrete decks follows the frame erection three floors behind. This responds to the fact that the metal floor decks support their corresponding concrete decks, and that enough distance should be present between the concrete floor casting and the structural frame erection.)

5. Fireproofing of the structural frame is preceded by concrete deck placing. (If the frame alternative is a steel frame, typical construction practice involves its fireproofing with a sprayed compound. Because the crew that performs the spraying requires a firm working surface, the fireproofing of a floor is normally preceded by the placing of the floor’s concrete deck. One floor is kept between these two operations as a buffer to avoid the cracking of the sprayed compound under the metal deck, from the loads imposed by the casting of the next floor’s concrete deck.)

6. Roofing is preceded by the roof frame erection. (The roof is supported by the roof frame.)

* Units of Lag and Duration are weeks.
** Pace1 is the duration per floor of Erecting Frame.
*** Pace2 is the duration per floor of Wall_enclosure construction, which must be equal to or greater than Pace1.
7. Elevator installation is preceded by roofing. (The installation of the elevator equipment requires
the weather protection of an impervious roof.)

8. Rough-in work is preceded by fireproofing. (If the frame alternative is a steel frame, the rough-
in work typically follows the fireproofing operation. Because the fireproofing is performed by spraying
a compound that affects other crews, a one-floor buffer is kept between these activities.)

9. Rough-in work is preceded by frame erection. For the steel frame case, rough-in work is
preceded by the application of fireproofing. In the cast-in-place concrete frame case, rough-in work is
directly preceded by the frame erection activity. In both cases rough-in work is also performed
concurrently with framing activities (embedded conduit pipes, slab sleeves, etc.) and therefore normally
it is not relevant for total duration calculation.

10. Wall enclosure is preceded by fireproofing. (If the frame alternative is a steel frame, the wall
enclosure typically follows the fireproofing operation. Since the fireproofing compound affects other
crews, a one-floor buffer is kept between these activities.)

11. Wall enclosure is preceded by frame erection. For the steel frame case, wall enclosure is
preceded by the application of fireproofing. In the cast-in-place concrete frame case, wall enclosure is
directly preceded by the frame erection activity.

12. Interior finishes are preceded by wall enclosure work and roofing. (The interior finishes require
a weather-protected environment provided by the exterior walls and the roof.)

13. The interior finishes are performed by a number of crews that successively progress through
each floor. Typically, these crews include plumbing, electrical, heating, ventilation, and air-conditioning
(HVAC), wall finishes, floor surfacing, ceiling, and door/window/glazing crews. As a consequence, there
is an overlap in the execution of interior finishes for the different floors. This is represented here by
having floor finishes in floor "i" precede floor finishes in floor "i+1," with a start-to-start relationship and
a lag equal to the progression of the exterior walls installation. The reason for this lag is that the interior
finishes need the weather protection offered by the wall enclosure.

14. First floor finishes are performed last in the interior finishes sequence. This is because the
crews operating in the building typically enter and exit through the first floor, and could damage finishes
already in place.

15. Final clean-up follows the completion of interior finishes.

Activity Durations

For preliminary scheduling, experienced schedulers establish approximate activity durations based
on general building size and on past experience. The intention here was to acquire the rules of thumb
used to establish approximate durations. The determination of optimal activity durations, performed
through resource allocation and leveling, is beyond the scope of this work.

Rules of thumb were acquired to determine default durations for the different activities considered.
While these default durations may vary for specific projects, they do provide a base for a reasonable
duration estimate. Moreover, CODES provides the user with the capability to override its default values.
CODES assumes the following activity durations:

1. Mobilization: A default duration of 2 weeks is defined for this activity.
2. Site Preparation and Foundation Work: For this activity, three possible cases are considered:

a. For buildings with no basement, the default duration is 4 weeks.
b. For buildings with one basement, the default duration is 6 weeks.
c. For buildings with two basements, the default duration is 10 weeks.

These durations assume close-to-ideal circumstances (good soil, no dewatering required, no underpinning, etc.).

3. Frame Erection: The duration of this activity depends on the number of floors in the building. For the ranges of floor area (5000 to 20,000 sq ft of typical floor area) addressed here, the default duration is calculated on the basis of a frame erection pace of one floor per week. In the case of a steel frame, the concrete deck installation activity follows three floors behind, at the same pace. Fireproofing follows the concrete deck placing, two floors behind, also with the same pace.

4. Rough-in Work: The rough-in follows the frame erection pace. The default duration is set as the number of floors times the frame erection pace.

5. Roof Installation: A default duration of 2 weeks is used for this activity.

6. Elevator Installation: If an elevator is required, its default duration is computed as the maximum of: (1) 12 weeks, or (2) the time interval in weeks between roofing completion and first floor completion.

7. Wall Enclosure: The exterior walls and windows installation duration is also related to the number of floors. The default duration is calculated on the basis of a progression pace of 2 weeks per floor.

8. Interior Finishes: The interior finishes activity is broken into interior finishes for each floor. The first floor normally takes longer to be finished, because the work required for the lobby is labor intensive. The default duration for the first floor finishing is 9 weeks. The default durations for finishing the other floors are related to the degree of interior partitioning. If the floors are highly partitioned (as in residential construction), the default duration for their interior finishes is set to 8 weeks per floor. For moderately partitioned floors, the default duration is 5 weeks per floor.

9. Final Clean-up: A default duration of 5 weeks is given to this activity for final clean-up and punch list procedures.

10. Demobilization: This activity has a default duration of 2 weeks.

Weather and Procurement Constraints

It is possible to perform any type of work in almost any weather if enough protection and resources are available. However, it is expensive and time demanding to install temporary weather protection for unprotected weather-sensitive activities. Experienced schedulers consider the constraints of expected weather conditions.

The weather considerations observed from the interviewed schedulers are restricted to the Midwest region, the location of most of the scheduling cases analyzed. However, regardless of geographical location, a construction schedule must be checked against local expected weather conditions and appropriate schedule adjustments should be made.Schedulers usually consider the following weather guidelines.
1. Site Preparation and Foundation work should not begin before early Spring (approximately mid-March). This prevents: (1) the difficulty of performing earthwork operations in frozen ground, and (2) potential problems of performing concreting operations (foundations) in cold weather.¹

2. Building enclosure (roof, skin) should be complete by late Fall (approximately the end of November) if interior finishing is scheduled during winter time. This allows the progress of interior finishes into an enclosed environment. Heating is then facilitated and moisture protection enhanced.

3. Concrete casting, spraying of fireproofing, and masonry work should not proceed during cold weather. These activities involve materials that require temperatures well above freezing to set and cure adequately.

Procurement time is the time associated with fabrication and delivery of items to be installed during construction. No matter how carefully and precisely construction operations are planned, substantial delays can be expected if there is insufficient or inaccurate consideration of procurement constraints. Nontypical items are especially critical from a procurement perspective. Items like structural steel, elevators, glazed curtain walls, etc. require careful procurement planning.

³ *ACI Manual of Concrete Practice, Part 2: Construction Practices and Inspection; Pavements, ACI88* (American Concrete Institute, Detroit, Michigan, 1988).
3 PROTOTYPE IMPLEMENTATION

Overview

As mentioned earlier, the platform used is KnowledgePro, an expert system tool written in Turbo Pascal. KnowledgePro runs on IBM PC/XT, AT, or compatible computers with a minimum of 640K random access memory (RAM) and a hard disk. KnowledgePro has a backward-chaining inference engine and other KBS basic features.

The objective of the prototype development phase was to produce a tool able to estimate project construction duration, based on a representation of the activity definition, sequencing, and duration estimation issues described above. CODES is the initial working prototype of this tool. Additional development, validation, and field testing of CODES are still required.

Figure 2 shows the overall system operation. A typical CODES session starts with a welcome window and system description. After the initialization of some global variables, the user is asked to provide the necessary information related to the particular project being scheduled. The main system objective is to set up a list of all the major activities and the related values (Figure 3) and to output it to the screen and to text files.

The attributes of each activity are determined with rules and critical path method (CPM) calculations. Main activity attributes are: activity duration, precedence relationships, lags associated to precedence relationships, and start and finish times. The attributes determining rules are summarized in the LAG and DURATION columns of Table 2, and in Figure 3.

All major activities (like Mobilization, Rough in, Roofing, etc.) are considered as frames (or topics) and the logical relationships between them are described by attributes and their values. The attributes can be activity, predecessor, relation, lag, duration, early start time, and early finish time. The rules are expressed in an "IF--THEN--ELSE" form and are used to determine activity duration and predecessors.

Appendix A provides a detailed explanation of how major activity information is incorporated in the prototype. This is done by showing how enclosure is implemented. Appendix B provides a comprehensive program source code listing.

Example Run

The input to the system is menu-driven. Table 3 lists example run input and output for a six-story office building with a floor area of 15,000 sq ft. The building has one basement, a steel frame, and a masonry and windows enclosure. Some corresponding screen displays are shown in Figures 4 through 10.

In step 9, the user may also select "prompt user for key values." If this alternative is selected, the system displays the default parameters, which the user can then confirm or override. This alternative is discussed below.

Through a hypertext system, the user may get more information about menu terms and items. The ASK screen contains an area of highlighted text, linked to a message. If the user wants more information about the text, a press of the F4 "View" function key opens a window to display an explanatory message. If the user is already familiar with the highlighted concept, the linked information can be ignored. For example, an experienced scheduler will know the term "Procurement" and need not invoke the message. However, a trainee may need more information to understand and use the concept. The trainee merely points to "Procurement" to call for information on the topic of materials procurement for the activity under consideration. The hypertext system is transparent to the novice.

Explanation

place_concr_deck is proposed to be started on 18 / 17 / 1991 and duration is 7 weeks.
It is a weather sensitive activity. Normally it requires good weather for its installation (no precipitation, warm temperatures). If it is going to be performed during cold or precipitation intensive periods, substantial delays are expected.

Figure 8. Weather Conflict Warning.

activity is: place_concr_deck
preceded by: erect_frame
relation is: ss
lag is: 3 weeks
duration is: 7 weeks
start date is: 18 / 17 / 1991
finish date is: 12 / 4 / 1991

place_concr_deck is proposed to be started on 18 / 17 / 1991 and duration is 7 weeks.
It is a weather sensitive activity. Normally it requires good weather for its installation (no precipitation, warm temperatures). If it is going to be performed during cold or precipitation intensive periods, substantial delays are expected.

Figure 9. Parameter Selection for Value Change.
Figure 10. New Value for Selected Parameter.

After this input is completed, the system automatically processes the estimation based on the major activities discussed earlier and uses CPM to calculate the duration. The screen displays a bar chart, and both the bar chart and a text file are output to two disk files, which can be printed after processing ends (Figures 11 and 12).

After processing, the system returns to the menu illustrated in Figure 6. Here the user may also select the option to "prompt user for key values".

After the key values prompt is selected, CODES requests whether to ignore or detect weather conflicts. If the option "detect weather conflicts" is selected, the system will provide warnings related to weather constraints. (At present the system action is limited to warn of conflicts between weather-sensitive activities and expected adverse weather periods.) Figure 8 shows a weather warning that applies to the placing of concrete decks.

If the option "prompt user for key values" was selected, CODES displays on the screen the following activity characteristics: (1) activity label, (2) predecessors, (3) precedence relationship type and lag, (4) activity duration, and (5) early start and early finish. An option is available that provides additional detail on the nature of each activity and its precedence relationships. The user may also modify some of the activity characteristics (Figures 9 and 10).

Once all activities have been displayed for the user's confirmation or modification, the system displays the updated activity bar chart. It then returns to the option menu (Figure 6), allowing the user either to perform more iterations to incorporate additional activity changes or to end the session.

Figure 12. Text File.
Summary of Workshop To Review the CODES Prototype

A Workshop was conducted on 20 September 1990 with participants from different Corps of Engineers districts and the Office of Chief of Engineers. The objective of this workshop was to demonstrate the CODES prototype to a group of potential users and to invite their suggestions for improvement.

A number of comments, suggestions, and recommendations were made:

1. It was recommended that the system's scope be extended to include duration estimation of more construction project types, such as industrial buildings, hospitals, hangars, maintenance facilities, etc. It was also suggested that the system should be altered to handle multifacility projects (i.e., more than one building per project).

2. The degree of user control was welcomed by the workshop participants, but it was suggested to increase it. An important recommended feature was an option for the user to add and remove activities. It was also suggested that the program provide information about activity timing (start and end dates, plus a view of the current project bar chart) when displaying each activity for user feedback. (This recommendation has been already partially incorporated.)

3. Workshop participants agreed that an important factor in determining project duration is procurement time. It was recommended that the program incorporate procurement activities for procurement-critical items like structural steel and elevators. A procurement activity should be as long as the material/equipment takes to be delivered, and should precede the activity that installs that material/equipment.

4. Currently the prototype only warns about potential weather conflicts. It was suggested that the user be able to respond to these weather warnings by: (1) delaying the start of the activity until more favorable weather is expected, (2) extend activity duration to allow for time lost to unfavorable weather or spent in weather-protecting the operation, or (3) modify the logic of the activities to tackle nonweather-sensitive operations instead of weather-sensitive work.

5. The development of the prototype has been concurrent with other research work that assesses severe weather impact on construction operations. It was suggested to consider incorporating the results of the severe weather impact study into CODES.

6. The prototype currently handles typical construction features. However, project-specific features also affect estimating project duration. The system should also be able to address project-specific features. It was suggested that the user be given the ability to add/remove/modify the system-provided set of activities and their characteristics. In this way, the system-provided template could be tailored to fit specific project characteristics.

Several of these recommendations have already been incorporated into CODES. The start and end dates are now shown whenever a user opts to change any activity-specific information. The knowledge base was given the added capability of representing procurement constraints, by incorporating the concept of "procurement activity." A procurement activity represents the time required to acquire specific materials or equipment associated with an installation activity; so the procurement activity must logically precede the installation activity. For example, the activity "Steel Procurement" would precede the actual installation of the steel frame. Elevator Installation is now an optional activity. The user may remove this activity if the facility under analysis does not have an elevator.
SUMMARY

This study developed a KBS prototype (CODES) that incorporates scheduling knowledge to break down the construction phase into a set of logically sequenced major activities. Rules of thumb acquired from experienced schedulers were incorporated into CODES to estimate activity durations. The prototype system currently applies to office/residential building construction.

Using a KBS approach to forecast project construction duration is helpful to users with limited construction duration estimation knowledge. It can also be a useful tool to assist knowledgeable planners, since it expedites and provides a smart check list for duration estimation. CODES provides the ability to produce a duration estimate within minutes, and allows the incorporation of user changes that adjust the program to particular project characteristics.

This work is presently at the validation and testing stage. A program for verifying and enhancing the current CODES working prototype will be undertaken, including:

1. Hands-on review by engineering and construction district personnel to obtain direct feedback from potential users

2. A continued effort to incorporate the recommendations gained from that review and from the workshop of 20 September

3. A test of the system by applying the program to schedule records from selected building construction projects performed in the past by Corps of Engineers districts.

APPENDIX A: Enclosure Implementation

Figure A1 shows a flow chart for the activity Enclosure. The flow chart is explained as follows:

Determine the activity:

Activity is Enclosure.

Determine the predecessor:

If type of structure is steel frame,
then predecessor is fireproofing,
else predecessor is erect frame.

Determine the lag:

If structural type is steel frame,
then lag is 2 times the duration per floor of frame erection,
else lag is number of floors below ground plus the duration per floor of frame erection.

Determine the relation:

Relation is ss, therefore, Enclosure can only be started after the predecessor has been started.

Determine the duration per floor (pace):

If type of enclosure is glass wall,
then pace is 3 weeks per floor,
else pace is 2 weeks per floor.

If pace of enclosure is less than pace of frame erection,
then pace of enclosure is equal to pace of frame erection.

Determine the duration of Enclosure:

Duration equals the duration per floor times the number of floors above the ground.

Determine the Early Start time:

Using CPM function to calculate the Early Start time.

Determine the Early Finish time:

Early Finish time equals Early Start time plus duration.
Figure A1. Flow Chart of Enclosure.

Construction Duration Estimating System *

end. (* project ]const *)

end. (* project ]const *)

TEXT FILE FOR THE COMPREHENSIVE CODE

//description

* Construction Duration Estimating System *

49
This system is focused on the construction duration estimation of mid-rise buildings of residential/commercial nature. It is limited to buildings with steel, cast in place concrete or masonry structural frame type and with a maximum of two floors below ground. Minimum site work and very simple excavation are assumed. The estimation the system performs is valid for buildings with a typical floor size of up to 25000 square feet per typical floor.

This is a prototype of the system, if you have any questions or comments, please contact Dr. Diego Echeverry at DEPARTMENT OF THE ARMY, CONSTRUCTION ENGINEERING RESEARCH LABORATORY, Construction Management Team, Champaign, Illinois 61824-4005

//
// toxic dump site
For toxic dump site, substantial delays should be expected for site cleaning.
//
// mobilization
Mobilization is the first activity of the construction.
//
// site and foundation
The duration for site preparation and foundation is based on the number of floors below ground. The default values are:

No basement ...... 4 weeks
1 floor of basement ...... 6 weeks
2 floors of basement ...... 10 weeks

Site preparation and foundation should start not earlier than March 15 and end not later than December 1. If it happens in this period, a longer duration should be expected.

//
// frame erection
The default value of pace of frame erection is 1 week/floor. Duration = number of floors * pace of frame erection.
//
// install concrete deck
Install concrete deck is an activity sensitive to weather. If it is performed during hard-freeze prone periods (December through mid March in the Midwest) and temporary protection and heating are not used, substantial delays should be expected.
//
// fire proofing
Fire proofing is an activity sensitive to weather.
If it is performed during hard-freeze prone periods (December through mid March in the Midwest) and temporary protection and heating are not used, substantial delays should be expected.

//
Roofing
Roofing is a weather sensitive activity. Normally it requires good weather for its installation (no precipitation, warm temperatures). If it is performed during cold or precipitation intensive periods, substantial delays should be expected.

//
rough in
The activities involved here are plumbing, electrical and HVAC risers and mains.

Duration of rough in = number of floors * pace of frame erection.

//
enclosure installation
Three kinds of enclosure alternatives are considered in the system. Here is a list with the default progression paces:

- precast panel/windows --- 2 weeks/floor
- glass wall --- 3 weeks/floor
- masonry/windows --- 2 weeks/floor

Ideally a contractor wants to have the building enclosed prior to the arrival of cold weather. If this is not possible, delays should be expected.

//
elevator installation
Duration of elevator installation may be longer than 12 weeks (default value) to have the same finish time as interior finishing.

//
Interior finishing
The duration of interior finishing is correlated to the amount of interior partition (or walls) to be installed.

- finishing of the first floor -- 6 weeks/floor
- residential building -- 8 weeks/floor
- office building:
  - highly partitioned -- 8 weeks/floor
  - moderately partitioned -- 5 weeks/floor.
clean up
Clean up includes activities like punch-list, final cleaning and final tests.

procurement
Timely procurement of activity resources with long lead deliveries or which are scarce in a particular environment is essential to avoid delays.

Weather
Normally it requires good weather condition, warm and less precipitation, for weather sensitive activities such as site preparation, foundation, concrete deck installation, fire proofing, roofing, enclosure, etc. Otherwise, substantial delays could be expected.

Weather-duration
It is a weather sensitive activity. Normally it requires good weather for its installation (no precipitation, warm temperatures). If it is going to be performed during cold or precipitation intensive periods, substantial delays are expected.

type of structure
Two types of structures, steel frame and cast in place concrete are currently supported by this system. Other types of structures will be considered in the future.

floor area case 1
The system might over estimate for this size of building footprint. Process will continue.

floor area case 3
This range is at the upper limit of the range for which a floor is not subdivided into work areas. Process will continue, assuming that 1 floor = 1 work area.

floor area case 4
For this range it is very likely that a floor will be subdivided into two or more work areas. The system does not handle this case at present.

TEXT FILE OF PROCUREMENT MESSAGES

frame erection
Structural steel takes more than 12 to 15 weeks to be delivered after it is ordered.
elevator installation
Order elevator one year earlier of installation.

//

closure installation
Order windows with necessary anticipation. This may vary between a few weeks to several months.

//

Interior finishing
Order mechanical and electrical equipments with necessary anticipation.

//

procurement
Timely procurement of activity resources with long lead deliveries or which are scarce in a particular environment is essential to avoid delays.
