Software reuse is the taking of any code or code segment and using it again to meet a specific need. Software reusability involves not only the reuse of software, but also how that software is designed. In other words, it involves designing totally self-contained software components. Each component should be easily modifiable to meet a potential user's need. This paper reports the prototypical implementation of a software library that uses the faceted cataloging scheme. It is designed to act as an interface between the user and a reusable software system. The prototype can be used to catalog and retrieve software components. Within the realm of this prototype, which is a domain-specific implementation, the number of facets used in the interface may be reduced while still achieving the same search and retrieval results.
A REUSABLE SOFTWARE CATALOG INTERFACE

M. Sameck

Thesis Adviser

Dean of the Graduate College
ACKNOWLEDGEMENTS

I wish to express my sincere appreciation to Dr. Mansur H. Samadzadeh for his encouragement and advice throughout my thesis research. His willingness to give guidance and direction made this a meaningful learning experience. I also wish to thank Drs. G.E. Hedrick and John P. Chandler for serving on my graduate committee.

I also wish to thank Rohinton Mistry and Winai Wichaipanitch for the use of their Operating Systems II projects as test data.

A very special thanks to my wife, Terri, for her patience and understanding during the course work and thesis preparation; her assistance in preparing the manuscript was invaluable. To my sons, Jacob and James, thanks for not giving up when I would say "wait a minute." It's time to play ball.

CHAPTER I

INTRODUCTION

Software reuse is currently a topic of great interest in the theory and practice of computer science in both academia and industrial research. Reducing software development cost through reuse of previously written and debugged code is practiced in many forms today and it "is an effective strategy for developers to reduce implementation cost" [PA90]; however, it is usually at the individual programmer level and very informal, based on one person's stock and his/her concept of what can be reused. By combining the efforts of a set of programmers at a given site, reuse libraries can be formed. Each programmer can then draw on source code from this library to accomplish a given task.

The next step is to make the use of the library efficient enough that the programmers would be willing to use it regularly, both as a customer and a contributor. The software components in the library must be readily accessible. A means must be devised to retrieve the closest match that meets a programmer's need with the least amount of modification.
In this thesis, the results of current work is examined and the most accurate library interface is identified. For this work, the interface is defined as the set of parameters that most clearly define a software component thus making its retrieval possible.

To demonstrate the feasibility of this task, a partial implementation of a software library is given. The data manipulated is the set of parameters used to describe each member of the software library (hereafter referred to as the repository). Identifying the most efficient method to store components is a topic for future research.

The concept of this implementation follows the basic structure proposed by Kazerooni-Zand, Samadzadeh, and George [KS90]. In their work, they deal with reuse at the object code level. Their system involves three major subsystems. The Identification Mechanism (IDM) is designed to select those components that meet a programmer's need. The Software Control Mechanism (SCM) is designed to provide access to different versions of a program or component; it receives input from the IDM. The Interface is designed to act as a pre and post compiler; it coordinates the micro-incremental compilation between their Reuse of Persistent Code and Object Code system and the compiler [KS90].

This thesis deals only with the action taking place within the IDM. The interface will be the parametrization of the detailed description of all components in the
software repository. In terms of the system defined by Kazerooni-Zand et al. [KS90], this is the Software Attribute Database. The level of reuse in this work is restricted to source code.
"Software reuse" is the taking of any code or code segment and using it again to meet a specific need. "Software reusability" involves not only the reuse of software, but also how that software is designed. In other words, it involves designing software components to be totally self-contained needing no outside code to accomplish their task, or if help is needed, knowing where to find it. Each component should be easily modifiable to meet a potential user's need.

As stated by Biggerstaff and Perlis, "software reuse is the reapplication of a variety of kinds of knowledge about one system to another similar system in order to reduce the effort of development and maintenance of that other system" [BP89a]. Reusability can mean the reuse of ideas as well as the reuse of components. So when an algorithm is used repeatedly, the algorithm is being reused.

According to Biggerstaff and Perlis [BP89a], software reuse has been in use for a number of years to a limited and informal extent. In many cases, it is limited to the knowledge of an earlier system that is similar to the
Reuse figures have been reported as high as 80%, but on average the figure is considered to be much lower, possibly as low as 5%. Other items of reuse such as life-cycle objects (requirements, designs, and test plans) have even lower rates of reuse [FG89] [FG90].

Portability can be considered a subarea of reusability. Portability is defined in general terms as "running a program in a host environment that is somehow different from the one for which it was designed" [JA88].

Portability became popular with the advent of the C programming language though it was an issue long before the appearance of C. As early as the late 1950's and early 1960's, COBOL was defined as a standard business language. Two corporations developed compilers late in 1960 and exchanged code [JA88]. With a minimum number of modifications, the code ran on both machines. However, just because a piece of code is written in COBOL or C (i.e., a "portable" language), it does not mean the program is necessarily portable [JA88]. Likewise, because a portion of a program is reused, it does not mean that the code is reusable in the sense of software reusability.

Basili approaches software reuse from the viewpoint of software maintenance [BA90]. He details three models that can be used during the process of updating an old system.
while using the old code as a bank of reusable code to create the new system. These three models are described below.

The "quick-fix" model uses the existing system. Modifications are made to the source code and documentation as necessary.

The "iterative-enhancement" model is designed to be used when all the requirements of the system are not known or the developer is not capable of building the full system. This model, which is well-suited to software maintenance, also starts with the existing system together with its requirements and documentation. It is an evolutionary process that allows for updating and redesigning of the system based on analysis of the system as the work progresses.

The "full-reuse" model begins with the requirements of the new system and uses components of the old system as needed along with other components that may be in the software repository. This model assumes that the existing components are well documented or that they are documented as they are added to the repository [BA90].

Basili does not go into the detail of cataloging the components for his models. However, in the case of the full reuse model, a catalog interface describing each member in the set of components to be used for the reuse project could enhance the model's usefulness.
Different Approaches to Reusability

Various concepts of software reusability have been presented by researchers. Prieto-Diaz and Freeman present a software classification scheme used to catalog pieces of software for future use [PF87]. The scheme enables the user to give parameters for a search and then the system selects and recommends software modules that match or closely match the parameters. The parameters are part of the interface used for the presented system.

Prieto-Diaz and Freeman's scheme is divided into two major areas: functionality and environment. Each area is further subdivided into three parameters. Functionality is described by function, objects, and medium. Function is self-explanatory; it describes what the software does, i.e., the action. Object describes the objects manipulated by the function, and medium describes the data structure(s) or device(s) that the function uses.

The environment is broken down into system type, functional area, and setting. The system type "refers to functionally identifiable, application-independent modules, usually including more than one component." Functional area describes "application-dependent activities usually defined by an established set of procedures." And the setting describes "where the application is exercised" [PF87].

The facets of this scheme form a sextuple that describes the respective components in the software reposi-
tory. To insure a uniform meaning for the sextuple, vocabulary control is imposed to facilitate comparisons. A thesaurus is used to convert all of the definitions to descriptive words of like meaning. This lends consistency to the comparisons.

A partially weighted graph (Figure 1) is used to help identify a closely related term when one of the members of the sextuple is not found. The graph is a DAG, Directed Acyclic Graph, with each of the nodes being "supertypes that denote general concepts relating two or more terms" [PF87]. Weights are assigned to the edges using a software
engineering perspective; the closer the perceived proximity of the terms, the lower the weight assigned to the edge connecting the two terms. When a query is made and a term is not matched, the graph is consulted to find closely matching terms, and this gives the user a set of closely related components to choose from.

To define the software components further, Kazerooni-Zand, Samadzadeh, and George start with Prieto-Diaz and Freeman's faceted scheme and add the implementation environment. It is composed of two elements: language and machine [KS90].

The Reuse of Persistent Code and Object Code (ROPCO), the system proposed by Kazerooni-Zand, Samadzadeh, and George, deals with reuse at a very low level. Machine dependency becomes much more important when attempting the reuse of object code as compared with source code.

The ROPCO system is composed of three major subsystems: the Identification Mechanism (IDM), the Software Control Mechanism (SCM), and the Interface. The function of the IDM is to identify and select the programs or modules that meet the user or programmer's requirements. Each element in the system has a record in the Software Attribute Database (SADB). This record is a unique identifier to its assigned element and is used throughout the ROPCO system to identify a particular element. The IDM prompts the user for the functional and environment attributes as defined by Prieto-
Diaz and Freeman [PF87], and the implementation environment as defined by Kazerooni-Zand et al. [KS90]. Using the attributes input by the user, the SADB is accessed and one or more elements are chosen; the selections are based on the descriptions in the SADB and the proximity distance model [PF87].

Kernighan uses the UNIX\textsuperscript{1} system as an example of an environment that facilitates reusability. By using system utilities, he proposes that one can build more complicated programs and utilities using shell scripts or the source code of the system utilities [KE84].

Caldiera and Basili approach software reusability by splitting the traditional life cycle models into two parts. The first part is the project and the second is the factory [CB91]. The project delivers the software system to the customer. As a need for a component is developed by the project, it is sent to the factory. The factory deals with extracting and packaging reusable components. It also has to have a detailed knowledge of the project it is supporting.

In their system, all components, which are selected for possible addition to the software repository, go through a two-phase evaluation. Phase one, the identification phase, consists of three steps: the definition of the reusability

\textsuperscript{1}UNIX is a trademark of AT&T.
attributes model, extraction of the component, and application of the model. Phase two, the component qualification phase, is composed of six steps: generation of the functional specification; generation of the test cases; classification of the component; development of the reuser's manual; storage; and feedback.

Phase one is automated using software models and metrics. Components that pass this phase are analyzed by a domain expert. Any component whose functional specification is not relevant, or is incorrect, is thrown away. The reason for eliminating the component is documented; this aids in the development of future reusable components.

A component is then run through a series of tests that are based on its functional specification. If the tests are failed, then once again the component is discarded and the reason is documented. At this point, any component that has survived is classified and documented for reuse. Each component is made an autonomous unit capable of being compiled without the addition of other files; any information that may have resided in other files (C include files for example) would have to be included in the component [CB91].

Purtilo and Atlee [PA90] introduced a language called NIMBLE that is used to ease the introduction of reusable modules into new applications. With NIMBLE, the difference between parameter orders is removed. NIMBLE provides
parameter coercion capabilities without changing the source code of a module. The actual and formal parameter lists are referred to as interface patterns. A mapping from the actual parameter list to a new "parametric" takes place to meet the needs of the module being called [PA90].

One of the motivations for the design of NIMBLE was the likelihood that modules that are semantically identical, but may be structurally different, are likely to become more prevalent as reusable software systems are developed. NIMBLE can be used to bridge the module interface gap and also it can widen the domain to which a module can be applied [PA90].

Frakes and Gandel [FG89] [FG90] discuss various methods of representing reusable software components including library science, knowledge based methods, and hypertext techniques. They define representation "as a language (textual, graphical, or other) used to describe a set of objects" [FG89].

The faceted classification scheme of Prieto-Diaz and Freeman [PF87] falls under the category of library science. To compensate for the narrow focus of an enumerated system such as the Dewey Decimal System, faceted schemes allow a subject area to be broken down into fundamental parts. These parts can then be synthesized to develop more descriptive representations [FG89].
Commercial component libraries such as GRACE (Generic Reusable ADA Components for Engineering) do exist. For instance, GRACE allows a user to choose from a list of ADA packages to accomplish common tasks such as managing stacks and queues. It uses a knowledge engineering approach to represent the software modules [FG89].

Chatterbox\(^2\), a graphical user interface library available from Courseware Applications, Inc., is a library of graphic routines for the C language. It performs the dirty work to create menu bars with pull-down menus and dialog boxes with keyboard and mouse support using the graphics routines of the supported compilers. The user decides what (s)he wants and then includes the necessary routines in his/her code. The routines are described in the Chatterbox reference manual. There is not an automated method available to pull routines together; the user must decide what (s)he wants by looking at the manual or by using past experience with the library. The user then goes to the Chatterbox source code and selects the necessary module or modules [SC90].

Reusability in Practice

Prieto-Diaz [PR91] states that a classification scheme for reusable software must meet the following criteria:

\(^2\)Chatterbox is a trademark of Courseware Applications, Inc.
1. It must accommodate continually expanding collections, a characteristic of most software organizations,

2. It must support finding components that are similar, not just exact matches,

3. It must support finding functionally equivalent components across domains,

4. It must be very precise and have high descriptive power (both are necessary conditions for classifying and cataloging software),

5. It must be easy to maintain, that is, add, delete, and update the class structure and vocabulary without any need to reclassify,

6. It must be easily usable by both the librarian and end user, and

7. It must be amenable to automation.

Prieto-Diaz [PR91] has worked with large corporations such as GTE Data Services (GTE DS) and the CONTEL Technology Center. While working at GTE DS, a 14 percent reuse factor with a savings of 1.5 million dollars reportedly has been realized the first year. A library "asset" was defined as any facility that could be reused in the production of software with the initial emphasis being reusable software components. It was found that 38 percent of the 190 assets in the library the first year were being "actively reused." The majority of the items in the library were components
with greater than 10,000 lines of code; the larger components provided a greater savings when reused. The faceted scheme was more effective in "domain specific collections than for broad, heterogeneous collections."

In his work at CONTEL, domain-specific reusable software repositories were established. The library system at CONTEL was developed to enable its easy integration into existing environments. This is an example of a library system that would be capable of being instantiated into multiple environments.

To encourage the use of the repository, monetary incentives were used to motivate the programmers, referred to as authors or asset providers, to write their software with reusability in mind, and to submit the new material for inclusion in the repository.
CHAPTER III

PROTOTYPE IMPLEMENTATION

General Overview

The main focus of this thesis is a prototype implementation of a software library. The prototype can be used to: (a) catalog software components using the faceted cataloging scheme presented by Prieto-Diaz and Freeman [PF87], and (b) retrieve components from a software repository. This implementation is used to catalog components at the source code level (other possibilities include the specification, design, and object code levels).

The system has three major sub-sections: adding components, querying the system for candidate components, and the common vocabulary or thesaurus. This system works within the confines of the Identification Mechanism (IDM) as defined by Kazerooni-Zand et al. [KS90].

Concept of the Design

The prototype was implemented using the C programming
language on an IBM PC/AT\textsuperscript{3} compatible. Microsoft Quick C compiler Version 2.5 was used for all coding and compiling.

The prototype requires eight supporting data files. The common vocabulary (hereafter referred to as the thesaurus) is contained in seven data files with the eighth file being the Software Attribute Database (SADB) as defined by Kazerooni-Zand et al. [KS90]. Each facet has its own thesaurus data file. The facets used for this prototype and the associated file names of their respective thesauruses are shown in TABLE I. The thesaurus file for language is included for information only; language is not used as a parameter during queries.

<table>
<thead>
<tr>
<th>FACETS WITH FILE NAMES</th>

</tbody>
</table>

Each line of a file is a comma-delimited list of descriptors with the first word on the line being the

\textsuperscript{3}IBM PC/AT is a trademark of International Business Machines Corp.
primary descriptor of that line. TABLE II shows a subset of the "function" common vocabulary. The first word of each line is the primary descriptor that will be used to define a component for this facet for all components described by one of the descriptors on that line. Given the set of descriptors "add, increment, total, sum" from the "function" thesaurus file, the user could enter any of the words as a legal input. If a user enters the word "sum," the thesaurus searches the data file of the respective facet. When sum is found, "add" is substituted for the user's input.

TABLE II
SAMPLE THESAURUS ENTRIES

| add, increment, total, sum |
| close, release, detach, disconnect, free |
| compare, test, relate, match, check, verify |
| complement, negate, invert |
| measure, count, advance, size, enumerate, list |

The thesaurus is accessed every time a user enters a descriptor (i.e., during cataloging and making queries). If the user enters a word not included in the thesaurus, (s)he is presented with a list from which to choose.

All of the supporting database functions are provided by source code reused from an earlier academic project (16 percent of the total lines of code are reused). Each of the
data files are indexed and accessed using inverted lists. With each data file, there are three supporting files. TABLE III shows the data files with their respective supporting files and TABLE IV gives the purpose of each of the data files.

</tbody>
</table>
The thesaurus was developed with the intended use of cataloging Operating Systems II class projects and their components as entries. This is a domain-specific implementation as was the implementation used at CONTEL by Prieto-Diaz [PR91]. It is possible to change the domain orientation by changing the common vocabulary in the thesaurus data files.

For this prototype implementation, the vocabulary consists of those terms needed to define the set of software components used as sample input. The list was limited to those terms needed to give an adequate sampling of the programs usefulness. Developing a comprehensive vocabulary for the operating systems domain is beyond the scope of this thesis.

User Interface

The prototype has three major sub-sections: adding components, querying the system for candidate components, and the common vocabulary or thesaurus.

The system is menu driven with the video display partitioned into multiple text windows. With few exceptions, pressing one key is all that is required to maneuver through the program. Figure 2 shows the opening menu where the user is presented with three choices. Each of the prompts are self-explanatory.
After electing to add a component to the repository, the user is prompted for the component name; the system must be able to find the component before it can be added to the repository. When the system is ready for the user to assign attributes to the module, the user will see the screen shown in Figure 3.

Attributes are entered as prompted. After all the descriptors have been input, the user is given a chance to make changes. When the descriptors are accepted, the component will be added to the system. No maintenance is required for this phase of the system.

When the user chooses Q at the opening menu, the system updates the Software Attribute Database (SADB) to insure that additions are included. The entering of attributes for
a query is done exactly as assigning attributes to a new component.

At each of the following prompts, enter the attribute that best describes this module or press ENTER to choose from a list.

CPU

1. Function:

Assigning attributes

FUNCTION is the action of the component.

Figure 3. Data Entry Screen.

When the list of desired attributes has been accepted, SADB is searched for all components that meet one or more of the desired attributes. After all exact matches are displayed, the user is presented with a message at the bottom of the screen containing a component name and the percentage of the attributes matched. The user can make the decision to view or bypass a component.

After all the possible candidates have been viewed or passed by, the user is asked if (s)he wants to keep the list of candidates. If a negative response is given, the list is discarded and the program returns to the main menu. If
accepted, the user is prompted for a file name and up to two lines of comments. Then the candidates with their attributes are dumped into the given file. While viewing the result of a system query, the user can press D and the system will display the facet definition at the bottom of the screen.

During the assigning of attributes and while making queries of the system, the thesaurus is available by pressing the ENTER key. When the key is pressed, a list of possible choices for the current facet is displayed on the right side of the screen. Also, if the user enters a descriptor not included in the common vocabulary, a list will appear on the right side of the screen. By selecting a letter corresponding to one of the given choices, the program inserts the selected descriptor. N and P are pressed to get the next and previous lists (see Figure 4).

The user cannot make any changes to the software repository from inside the program except for the addition of modules. To delete components from SADB, any ASCII text editor can be used. Each new line in the data file named ru.dta is a set of component descriptors. The line is a comma-delimited list containing the component name, function, object, medium, system type, functional area, setting, and language in that order. A ninth entry may be present if the user has assigned a custom attribute from a user-supplied thesaurus file. To delete a component from
SADB, the user must find the line containing its name and delete it. The next time the system is used to make a query, the SADB supporting files will be updated automatically.

At each of the following prompts, enter the attribute that best describes this module or press ENTER to choose from a list.

Choose from the given list.
Press M for the next list or P for the previous list.

Assigning attributes

MEDIUM refers to entities that serve as locales where the action takes place.

Figure 4. Data Entry Screen with Thesaurus.

To update one of the common vocabulary lists, any ASCII text editor can be used. The thesaurus entries are stored in a comma-delimited list with the first word of the list being the primary key for that particular set of descriptors. Each line of descriptors must be terminated with a carriage return (new line character, "\n"). The user can add or delete lines of descriptors. Also the user can add to or delete from the existing words. After changes are
made, at least one of the supporting files for the particular facet must be deleted. The next time the thesaurus accesses the list for the updated facet, its supporting files will be updated.

Sample Queries

The test data for this prototype implementation consists of components of varying lengths and purposes. Programs, of three programmers from a graduate level operating systems course, were broken into code segments of varying sizes based on each programmer's comments. A total of forty-three components were cataloged using the prototype.

Components range in size from three lines (simple string manipulations) to more than 700 lines. Some of the larger modules consist of multiple C functions that work in concert to accomplish an assigned task; in other cases, a module consists of a single function (some containing more that 250 lines of code). As expected, it was found that the smaller, more specialized the component, the easier it was to classify.

Using the program specification [SA91] that was used to develop the programs in the data set, a set of queries were developed to find components to meet the requirements of the principal routines: loader, memory, cpu, spooler, and scheduler (shown in order in TABLE V). The queries were
performed using four and six facets. Because this is a domain-specific implementation, the system type and setting facets were omitted from one set of queries. This was done to determine if the removal of the aforementioned facets changed the results of the queries measurably. There is a small set of components of a generic nature that can be used in any setting or system type as needed; however, in this sampling, their presence is insignificant.

</table>

As can be seen in TABLE V, the medium column is not used in every query. If a dominant medium could not be identified in a component during the cataloging of the component or in a component's specification, as in the case of the queries in TABLE V, it was omitted.
Query Results

To accomplish a partial validation of this prototype implementation, ten sample queries were completed; five queries using four facets (function, object, medium, functional area), and five queries using six facets (function, object, medium, system type, functional area, setting). The language facet was not used as a descriptor for queries because all of the components in the system are written in the same language, so this facet would not provide any useful information during a query.

Because the prototype finds every component in the system that meets one or more facets, the queries using six facets list some candidate components that meet only the system type and setting, or both. In this domain-specific implementation with the given data set, these facets do not provide any useful information. TABLE VI gives a summary of the number of components found using both four and six facets.

The left column of TABLE VI shows the number of attributes matched (i.e., if six attributes are entered as a query, "Exact" indicates an exact match of all the requested attributes; -1 indicates that five attributes are matched; -2 indicates that four attributes are matched; etc.). Columns $s_1$ through $s_5$ give the number of components found in samples 1 through 5 for the given number of facets.
TABLE VII shows at what point a search should be considered successful. As previously stated, the prototype delivers all components that meet one or more of the requested attributes. At some point, the components returned are of little or no value because of the particular facets matched. Because the results are based solely on attributes matched, an additional or alternate method must be developed to discriminate between the particular facets matched. This is a topic for future study. But for the purposes of this prototype, any component that is returned that contains two or more mismatched attributes should be discarded. The components represented in TABLE VII above the double line should be considered valid candidates, those below, invalid.

CHAPTER IV

SUMMARY AND FUTURE WORK

The aim of this thesis was to identify an accurate software catalog interface capable of correctly identifying software components and hence enabling their retrieval. The vehicle used to accomplish this was a partial, prototypical implementation of a software library.

Using the faceted cataloging scheme of Prieto-Diaz and Freeman [PF87] in a domain-specific library, it was decided that two facets (system type and setting) should be eliminated from the query process. This is due to the narrowness of the focus of the domain. As was reported in Chapter III, within the sample domain of this thesis, the results were the same with or without the use of the system type and setting for valid queries.

The interface developed as part of this thesis can be instantiated into different domains by changing the vocabulary. Also, it can be used at different levels of reuse other than source code such as design, specification, or object code levels.

In order to validate the prototype fully, it must be installed in an industrial setting to verify its performance.
over time. A system librarian would enhance the usefulness of the library by standardizing component descriptions. The program itself is easy to use, but the task of defining the software components is a time-consuming effort; time that a typical programmer may not care to expend (invest) to accomplish the task correctly. Programmers would have to be encouraged to develop their components with reusability in mind as was done at GTE DS and CONTEL [PR91].

To enhance the usefulness of this prototype implementation, the maintenance functions need to be automated. Also, the system needs a method to refine the results of the queries. The user should be given an indicator of the complexity required to modify the component to meet his/her need.

Future study is needed to determine the method used to store components ("assets" as defined by Prieto-Diaz [PR91]) most efficiently. Data compression may be one method to integrate into this prototype in its current form.

For the concept of reusability to become a widespread reality, it will require dedicated software librarians to accomplish the task of managing the repositories that will grow with time. This may open other specialized areas within the field of computer science.
BIBLIOGRAPHY

APPENDIX A

SOFTWARE REPOSITORY USER'S GUIDE
1. General Overview

This program is used to catalog software components using the faceted cataloging scheme presented by Rubén Prieto-Diaz and Peter Freeman [PF87], and to retrieve components from the software repository. This implementation is aimed at cataloging components at the source code level. The system has three major sub-sections: adding components, querying the system for candidate components, and the common vocabulary or thesaurus.

2. Adding Components

At the opening menu, you will be presented with three choices as follows.

The Opening Menu

(A)dd a component to the system.
(Q)uery the system for a component.
(R)xit to DOS.

Make your selection --
Choose A to add a component to the repository. The prompts are self-explanatory. Next you will be prompted for the component name; the system must be able to find the component before allowing it to be added to the repository. When the system is ready for you to assign attributes to the module, you will see the following screen.

Attribute Assignment Screen

At each of the following prompts, enter the attribute that best describes this module or press ENTER to choose from a list.

cpu.c

1. Function:

Assigning attributes

FUNCTION is the action of the component.

Enter the attributes as prompted. After all the descriptors have been input, you can make any changes. When you accept the entered list of descriptors, your component will be added to the system.
3. Making Queries of the System

From the opening menu choose Q. The system will then update the Software Attribute Database (SADB) to insure that the additions can be found. When making a query, enter the desired attributes just as you did when adding a component to the repository.

When you have accepted the list of desired attributes, SADB is searched for all components that meet one or more of the desired attributes. After all exact matches are displayed, a message will appear at the bottom of the screen containing a component name and the percentage of the attributes matched. If you wish to view the components attributes, press Y. After all the possible candidates have been view or passed by, you will be asked whether you want to keep the list of candidates. If you decline, the list is discarded and you are returned to the main menu. If you accept, you are prompted for a file name and up to two lines of comments. Subsequently, the candidates with their attributes are dumped into the file you have entered. While viewing the result of a system query, you can press D and the system will display the facet definition at the bottom of the screen.

4. Using the Thesaurus

During the assigning of attributes and while making queries of the system, the thesaurus is available by pressing the ENTER key. When the key is pressed, a list of
possible choices for the current facet is displayed on the right side of the screen. Also, If you enter a descriptor not included in the common vocabulary, a list will appear on the right side of the screen. Select the letter corresponding to your choice and the program will insert it for you. You may press N or P to get the next or previous lists.

Facet Options for the Attributes

At each of the following prompts, enter the attribute that best describes this module or press ENTER to choose from a list.

CPU

Choose from the given list. Press M for the next list or P for the previous list.

<table>
<thead>
<tr>
<th>Function: execute</th>
<th>Object: instruction</th>
<th>Medium:</th>
</tr>
</thead>
<tbody>
<tr>
<td>A * NOT APPLICABLE</td>
<td>B array</td>
<td>C buffer</td>
</tr>
<tr>
<td>D cards</td>
<td>E character</td>
<td>F disk</td>
</tr>
<tr>
<td>G double</td>
<td>H file</td>
<td>I float</td>
</tr>
<tr>
<td>J integer</td>
<td>K job</td>
<td>L keyboard</td>
</tr>
</tbody>
</table>

Assigning attributes

MEDIUM refers to entities that serve as locales where the action takes place.

5. Miscellaneous

You cannot make any changes to the software repository from inside the program except for the addition of modules. To update the common vocabulary or to delete components from
the system, see the System Administrator's Guide (Appendix B).

You may develop your own additional facet, if you so desire, to further define your software component(s). To do this, you need an ASCII text editor. Give the file whatever name you desire. In the file, arrange the descriptors so that each new line contains a new set of descriptors as shown below.

SAMPLE THESAURUS ENTRIES

add, increment, total, sum
close, release, detach, disconnect, free
compare, test, relate, match, check, verify
complement, negate, invert
measure, count, advance, size, enumerate, list

Each line must be terminated with a carriage return. As the C programming language is case sensitive, all searches of the descriptors are done in lowercase. Only the first word of the line can contain both upper and lowercase letters. Make sure the first word is the way you want is displayed. All remaining letters and words on the line should be in lower case to facilitate the search routines.

During the assigning of attributes or while making a query, you will be presented with an eighth prompt: "Other." At this prompt enter the user-defined facet. The
program will then prompt you for the file name of the file containing the common vocabulary for this facet. It is also possible to assign a second attribute from one of the program thesaurus files by entering the proper file name at the prompt.
APPENDIX B

SOFTWARE REPOSITORY SYSTEM ADMINISTRATOR'S GUIDE
1. General Overview

This program is used to catalog software components using the faceted cataloging scheme presented by Rubén Prieto-Díaz and Peter Freeman [PF87], and to retrieve components from the software repository. This implementation is aimed at cataloging components at the source code level. The system has three major sub-sections: adding components, querying the system for candidate components, and the common vocabulary or thesaurus.

2. Adding Components

At the opening menu, the user is presented with three choices as follows.

The Opening Menu

<table>
<thead>
<tr>
<th>Choice</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(A)</td>
<td>Add a component to the system.</td>
</tr>
<tr>
<td>(Q)</td>
<td>Query the system for a component.</td>
</tr>
<tr>
<td>(E)</td>
<td>Exit to DOS</td>
</tr>
</tbody>
</table>

Make your selection --
Choice A is for adding a component to the repository. The prompts are self-explanatory. Next the user is prompted for the component name; the system must be able to find the component before it can be added to the repository. When the system is ready for the user to assign attributes to the module, the user will see the following screen.

Attribute Assignment Screen

At each of the following prompts, enter the attribute that best describes this module or press ENTER to choose from a list.

cpu.c

1. Function:

Assigning attributes

FUNCTION is the action of the component.

The user enters the attributes as prompted. After all the descriptors have been input, the user can make changes. When the descriptors are accepted, the component will be
added to the system. No maintenance is required for this phase of the system.

3. Making Queries of the System

Once the user chooses Q at the opening menu, the system updates the Software Attribute Database (SADB) to insure that the additions are included. The entering of attributes for a query is done exactly as assigning attributes to a new component. When the list of desired attributes has been accepted, SADB is searched for all components that meet one or more of the desired attributes. All exact matches are displayed automatically. Subsequently, the user is presented with a message at the bottom of the screen containing a component name and the percentage of the attributes matched. The user can make the decision to view a component based on the number of attributes matched.

After all the possible candidates have been view or passed by, the user is asked if (s)he wants to keep the list of candidates. If a negative response is given, the list is discarded and the program returns to the main menu. If accepted, the user is prompted for a file name and up to two lines of comments. Subsequently, the candidates with their attributes are dumped into the file. While viewing the result of a system query, the user can press D and the system will display the facet definition at the bottom of the screen.
4. Using the Thesaurus

During the assigning of attributes and while making queries of the system, the thesaurus is available by pressing the ENTER key. When the key is pressed, a list of possible choices for the current facet is displayed on the right side of the screen. Also, if the user enters a descriptor not included in the common vocabulary, a list will appear on the right side of the screen. By selecting a letter corresponding to one of the given choices, the program inserts the selected attribute. N and P are presented to get the next and previous lists.

### Facet Options for the Attributes

At each of the following prompts, enter the attribute that best describes this nodule or press ENTER to choose from a list.

**CPU.C**

Choose from the given list.
Press M for the next list or P for the previous list.

| 1. Function: | execute |
| 2. Object:   | Instruction |
| 3. Medium:   |          |

MEDIUM refers to entities that serve as locales where the action takes place.
5. Updating SADB

NOTE: The user cannot make any changes to the software repository from inside the program except for addition of modules. It is recommended that the user not make any deletions from SADB.

For deletion of components from SADB, use any ASCII text editor. Each new line in the data file named ru.dta is a set of component descriptors. The line is a comma-delimited list containing the component name, function, object, medium, system type, functional area, setting, and language in that order. A ninth entry may be present if the user has assigned a custom attribute from a user supplied thesaurus file.

To delete a component from SADB, find the line containing its name and delete it. The next time the system is used to make a query, the SADB supporting files will be updated automatically.

6. Updating the Thesaurus/Common Vocabulary

NOTE: It is recommended that the user not be allowed to make changes to the thesaurus data files to avoid compromising the integrity of the supporting thesaurus.

To update one of the common vocabulary lists, use any ASCII text editor. The thesaurus entries are stored in a comma-delimited list with the first word of the list being the primary key for that particular set of descriptors. Each line of descriptors must be terminated with a carriage
return. It is recommended that the System Administrator perform all additions and deletions. After changes are made, at least one of the supporting files for the particular facet must be deleted. The next time the thesaurus accesses the list for the updated facet, its supporting files will be updated. The facets used for this program and the associated file names of their respective thesauruses are:

- function - funct.ths
- object - object.ths
- medium - medium.ths
- system type - systype.ths
- functional area - funcarea.ths
- setting - setting.ths

A thesaurus file for language (lang.ths) is included for information only; language is not used as a parameter during queries.

### NAMES OF THE DATA FILES WITH THEIR SUPPORTING FILES

<table>
<thead>
<tr>
<th>Data File</th>
<th>Wrd File</th>
<th>Inverted List</th>
<th>Inverted List Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>ru.dta</td>
<td>ru.wrd</td>
<td>ru.inv</td>
<td>ru.vdx</td>
</tr>
<tr>
<td>funct.ths</td>
<td>funct.wrd</td>
<td>funct.inv</td>
<td>funct.vdx</td>
</tr>
<tr>
<td>object.ths</td>
<td>object.wrd</td>
<td>object.inv</td>
<td>object.vdx</td>
</tr>
<tr>
<td>medium.ths</td>
<td>medium.wrd</td>
<td>medium.inv</td>
<td>medium.vdx</td>
</tr>
<tr>
<td>systype.ths</td>
<td>systype.wrd</td>
<td>systype.inv</td>
<td>systype.vdx</td>
</tr>
<tr>
<td>funcarea.ths</td>
<td>funcarea.wrd</td>
<td>funcarea.inv</td>
<td>funcarea.vdx</td>
</tr>
<tr>
<td>setting.ths</td>
<td>setting.wrd</td>
<td>setting.inv</td>
<td>setting.vdx</td>
</tr>
<tr>
<td>lang.ths</td>
<td>lang.wrd</td>
<td>lang.inv</td>
<td>lang.vdx</td>
</tr>
</tbody>
</table>
Below are the purposes and contents of the supporting files.

.wrd - contains all words in the data file with their line numbers that are used to create the inverted list

.inv - an inverted list for the data file

.vdx - the index file for the inverted list

This program creates the index entries for a hypertext system. It was developed on a 12 Mhz 80286 IBM AT compatible using Microsoft Quick C 2.0. The program is designed to make use of a hard disk. As the DOS sort utility is limited to < 64K, the data is read in blocks of 16K; this was the block size that produced the quickest run time on the development system. The blocks are sorted and then merged in the sort() function.

The hyper() is a road map for the control of this program. Each function is passed the name of the file that is to be manipulated. All i/o calls are made from within the respective functions.

```
#include "ru.h"
#include <malloc.h>
#include <ctype.h>
#define Max_line 500
#define Scr_size 1
#define Word_length 500

VITA

Joe E. Swanson

Candidate for the Degree of

Master of Science

Thesis: A REUSABLE SOFTWARE CATALOG INTERFACE

Major Field: Computer Science

Biographical:

Personal Data:

Civilian Education: Graduated from Guthrie High School, Guthrie, Oklahoma in May 1977; received Bachelor of Music Degree from Central State University at Edmond in May 1981; completed requirements for the Master of Science degree at Oklahoma State University in December 1991.

Military Education: Graduate of the following courses:
Transportation Officer Basic Course, August 1981;
Initial Entry Rotary Wing Course, May 1982;
Aviation Maintenance Officer Course, August 1983;
Aviation Officer Advanced Course, March 1986;
Combined Arms and Services Staff School, August 1989.
