**Abstract.** We discuss the problem of obtaining upper and lower bounds for the strain-energy density in linear anisotropic elastic materials. One set of bounds is given in terms of the *magnitude of the stress field*, another in terms of the *magnitude of the strain field*. Results of this kind play a major role in the analysis of Saint-Venant's Principle for anisotropic materials and structures. They are also useful in estimating global quantities such as total energies, buckling loads, and natural frequencies. For several classes of elastic symmetry (e.g., cubic, transversely isotropic, hexagonal, and tetragonal symmetry) the *optimal constants* appearing in these bounds are given explicitly in terms of the elastic constants. This makes the results directly accessible to the design engineer. Such explicit results are rare in the field of anisotropic elasticity. For more elaborate symmetries (e.g., orthotropic, monoclinic, and triclinic) the optimal constants depend on the solution of cubic and sextic equations, respectively.
Strain energy density bounds for linear anisotropic elastic materials

M.M. MEHRABADI, S.C. COWIN, and C.O. HORGAN

Abstract. Upper and lower bounds are presented for the magnitude of the strain energy density in linear anisotropic elastic materials. One set of bounds is given in terms of the magnitude of the stress field, another in terms of the magnitude of the strain field. Explicit algebraic formulas are given for the bounds in the case of cubic, transversely isotropic, hexagonal and tetragonal symmetry. In the case of orthotropic symmetry the explicit bounds depend upon the solution of a cubic equation, and in the case of the monoclinic and triclinic symmetries, on the solution of sixth order equations.

Bounds on the magnitude of the strain energy density in linear anisotropic elastic materials are needed in proofs of Saint-Venant’s principle for these materials (see, for example, Toupin [1], Horgan [2], and the review of Horgan and Knowles [3]). In this note we extend the method of bounding the strain energy density employed by Horgan [4] to include specific anisotropic elastic symmetries. We do this using a result of Mehrabadi and Cowin [5] in which the coefficients of elasticity are expressed as a second rank tensor in a six-dimensional space rather than as a fourth rank tensor in a three-dimensional space. The eigenvalues of the six-dimensional, second rank elasticity tensor are the numerical coefficients in the bounds obtained.

The anisotropic form of Hooke’s law is often written in indicial notation as

\[ T_{ij} = C_{ijkl} E_{kl}, \]  

(1)

where the \( C_{ijkl} \) are the components of the elasticity tensor. There are three important symmetry restrictions on the tensor \( C_{ijkl} \). These restrictions, which require that components with the subscripts \( ijk \), \( jik \), and \( kmj \) be equal, follow from the symmetry of the stress tensor, the symmetry of the strain tensor, and the requirement that no work be produced by the elastic material.
in a closed loading cycle, respectively. Written as a linear transformation in six dimensions, Hooke's law (1) has the representation, \( T = cE \), or

\[
\begin{bmatrix}
T_{11} \\
T_{22} \\
T_{23} \\
T_{13} \\
T_{12}
\end{bmatrix} =
\begin{bmatrix}
c_{11} & c_{12} & c_{13} & c_{14} & c_{15} & c_{16} \\
c_{12} & c_{22} & c_{23} & c_{24} & c_{25} & c_{26} \\
c_{13} & c_{23} & c_{33} & c_{34} & c_{35} & c_{36} \\
c_{14} & c_{24} & c_{34} & c_{44} & c_{45} & c_{46} \\
c_{15} & c_{25} & c_{35} & c_{45} & c_{55} & c_{56} \\
c_{16} & c_{26} & c_{36} & c_{46} & c_{56} & c_{66}
\end{bmatrix}
\begin{bmatrix}
E_{11} \\
E_{22} \\
E_{33} \\
2E_{23} \\
2E_{13} \\
2E_{12}
\end{bmatrix},
\]

(2)

in the notation of Voigt. The relationship of the components of \( C_{jkm} \) to the components of the symmetric matrix \( c \) is easily seen.

Introducing new notation, (2) can be rewritten in the form.

\[
\mathbf{\hat{T}} = \hat{c}\mathbf{\hat{E}},
\]

(3)

where the shearing components of these new six-dimensional stress and strain vectors, denoted by \( \mathbf{\hat{T}} \) and \( \mathbf{\hat{E}} \), respectively, are multiplied by \( \sqrt{2} \), and \( \hat{c} \) is a new six-by-six matrix. Thus the matrix form of (3) is given by

\[
\begin{bmatrix}
T_{11} \\
T_{22} \\
\sqrt{2}T_{23} \\
\sqrt{2}T_{13} \\
\sqrt{2}T_{12}
\end{bmatrix} =
\begin{bmatrix}
c_{11} & c_{12} & c_{13} & \sqrt{2}c_{14} & \sqrt{2}c_{15} & \sqrt{2}c_{16} \\
c_{12} & c_{22} & c_{23} & \sqrt{2}c_{24} & \sqrt{2}c_{25} & \sqrt{2}c_{26} \\
c_{13} & c_{23} & c_{33} & \sqrt{2}c_{34} & \sqrt{2}c_{35} & \sqrt{2}c_{36} \\
\sqrt{2}c_{14} & \sqrt{2}c_{24} & \sqrt{2}c_{34} & 2c_{44} & 2c_{45} & 2c_{46} \\
\sqrt{2}c_{15} & \sqrt{2}c_{25} & \sqrt{2}c_{35} & 2c_{45} & 2c_{55} & 2c_{56} \\
\sqrt{2}c_{16} & \sqrt{2}c_{26} & \sqrt{2}c_{36} & 2c_{46} & 2c_{56} & 2c_{66}
\end{bmatrix}
\begin{bmatrix}
E_{11} \\
E_{22} \\
E_{33} \\
2E_{23} \\
2E_{13} \\
2E_{12}
\end{bmatrix},
\]

(4)

The symmetric matrix \( \hat{c} \) can be shown, Mehrabadi and Cowin [5], to represent the components of a second rank tensor in a six-dimensional space, whereas the components of the matrix \( c \) appearing in (2) do not form a tensor. The inverse of the elasticity tensor \( \hat{c} \) is the compliance tensor \( \hat{\varepsilon} \) where \( \hat{\varepsilon} = \hat{c}^{-1} \), thus

\[
\mathbf{\hat{E}} = \hat{\varepsilon}\mathbf{\hat{T}},
\]

(5)

where \( \hat{\varepsilon} \) is also a second rank tensor in a six-dimensional space. The eigenvalues of the matrix \( \hat{c} \) are the six numbers \( \Lambda \) satisfying the equation

\[
(\hat{c} - \Lambda I)\hat{\mathbf{N}} = 0,
\]

(6)

and their inverses are the eigenvalues of the matrix \( \hat{\varepsilon} \)

\[
(\hat{\varepsilon} - (1/\Lambda) I)\hat{\mathbf{N}} = 0,
\]

(7)
Strain energy density bounds

where the vectors \( \hat{N} \) represent the eigenvectors of \( \hat{e} \) or \( \hat{\theta} \). The linear transformation (3) defined by \( \hat{e} \) is a six-dimensional symmetric transformation, assumed to be positive definite, which has, of course, six positive eigenvalues. These eigenvalues will be denoted by \( \Lambda_i, \ i = 1, \ldots, 6 \), and ordered by the inequalities \( \Lambda_1 \geq \cdots \geq \Lambda_6 > 0 \). It follows that

\[
\Lambda_6 |\hat{E}| \leq |\hat{T}| \leq \Lambda_1 |\hat{E}|, \quad \frac{1}{\Lambda_1} |\hat{T}| \leq |\hat{E}| \leq \frac{1}{\Lambda_6} |\hat{T}|, \tag{8}
\]

where the vertical bars on either side of a vector indicate the norm of the vector, e.g.

\[
|\hat{T}| = \sqrt{\hat{T} \cdot \hat{T}}. \tag{9}
\]

The strain energy density is denoted by \( \Sigma \) where

\[
2\Sigma = \hat{T} \cdot \hat{E} = (\hat{e}\hat{E}) \cdot \hat{E} = \hat{T} \cdot (\hat{e}\hat{E}), \tag{10}
\]

and it can be expressed in terms of the strain eigenvector \( |\hat{E}|\hat{N} \) using the eigenvalues of (6) as

\[
2\Sigma = |\hat{E}|^2 \left( \Lambda_1 |\hat{N}_1|^2 + \Lambda_2 |\hat{N}_2|^2 + \Lambda_3 |\hat{N}_3|^2 + \Lambda_4 |\hat{N}_4|^2 + \Lambda_5 |\hat{N}_5|^2 + \Lambda_6 |\hat{N}_6|^2 \right), \tag{11}
\]

or in terms of the stress eigenvector \( |\hat{T}|\hat{N} \) using the eigenvalues of (7) as

\[
2\Sigma = |\hat{T}|^2 \left( \frac{1}{\Lambda_1} |\hat{N}_1|^2 + \frac{1}{\Lambda_2} |\hat{N}_2|^2 + \frac{1}{\Lambda_3} |\hat{N}_3|^2 + \frac{1}{\Lambda_4} |\hat{N}_4|^2 + \frac{1}{\Lambda_5} |\hat{N}_5|^2 + \frac{1}{\Lambda_6} |\hat{N}_6|^2 \right). \tag{12}
\]

Recalling that the vector \( \hat{N} \) is a unit vector (\( \hat{N} \cdot \hat{N} = 1 \)) in six dimensions, recalling also the ordering of the eigenvalues by the inequalities \( \Lambda_1 \geq \cdots \geq \Lambda_6 > 0 \), the results (11) and (12) yield the inequalities

\[
\Lambda_6 |\hat{E}|^2 \leq 2\Sigma \leq \Lambda_1 |\hat{E}|^2, \quad \text{and} \quad \frac{1}{\Lambda_1} |\hat{T}|^2 \leq 2\Sigma \leq \frac{1}{\Lambda_6} |\hat{T}|^2, \tag{13}
\]

respectively. These inequalities represent the bounds of interest. For a particular elastic symmetry the bounds (13) are employed with the values of \( \Lambda_1 \) and \( \Lambda_6 \) taken to be the numerically largest and smallest, respectively, of the eigenvalues listed in Table I for that particular symmetry. The second of the inequalities (13) has been previously derived in [4] (p. 232) and illustrated...
Table 1. The sets of distinct eigenvalues $\Lambda$ for each of the ten distinct elastic symmetries. The multiplicity of these eigenvalues is discussed in [5].

Isotropic symmetry
\[ c_{11} + 2c_{12}, 2c_{44} \text{ (i.e., } 3\lambda + 2\mu, 2\mu) \]

Cubic symmetry
\[ c_{11} + 2c_{12}, c_{11} - c_{12}, 2c_{44} \]

Transversely isotropic symmetry
\[
\begin{align*}
\frac{1}{2}((c_{11} + c_{12} + c_{33}) + \sqrt{8c_{13}^2 + (c_{11} + c_{12} - c_{33})^2}), \\
\frac{1}{2}((c_{11} + c_{12} + c_{33}) - \sqrt{8c_{13}^2 + (c_{11} + c_{12} - c_{33})^2}), \\
\frac{1}{2}((c_{11} - c_{12} + 2c_{44} + \sqrt{16(c_{14}^2 + c_{15}^2}) + (c_{11} - c_{12} - 2c_{44})^2}), \\
\frac{1}{2}((c_{11} - c_{12} + 2c_{44} - \sqrt{16(c_{14}^2 + c_{15}^2}) + (c_{11} - c_{12} - 2c_{44})^2}).
\end{align*}
\]

Hexagonal (7) symmetry
\[
\begin{align*}
\frac{1}{2}((c_{11} + c_{12} + c_{33}) + \sqrt{8c_{13}^2 + (c_{11} + c_{12} - c_{33})^2}), \\
\frac{1}{2}((c_{11} + c_{12} + c_{33}) - \sqrt{8c_{13}^2 + (c_{11} + c_{12} - c_{33})^2}), \\
\frac{1}{2}((c_{11} - c_{12} + 2c_{44} + \sqrt{16(c_{14}^2 + c_{15}^2}) + (c_{11} - c_{12} - 2c_{44})^2}), \\
\frac{1}{2}((c_{11} - c_{12} + 2c_{44} - \sqrt{16(c_{14}^2 + c_{15}^2}) + (c_{11} - c_{12} - 2c_{44})^2}).
\end{align*}
\]

Hexagonal (6) symmetry
\[
\begin{align*}
\frac{1}{2}((c_{11} + c_{12} + c_{33}) + \sqrt{8c_{13}^2 + (c_{11} + c_{12} - c_{33})^2}), \\
\frac{1}{2}((c_{11} + c_{12} + c_{33}) - \sqrt{8c_{13}^2 + (c_{11} + c_{12} - c_{33})^2}), \\
\frac{1}{2}((c_{11} - c_{12} + 2c_{44} + \sqrt{16(c_{14}^2 + c_{15}^2}) + (c_{11} - c_{12} - 2c_{44})^2}), \\
\frac{1}{2}((c_{11} - c_{12} + 2c_{44} - \sqrt{16(c_{14}^2 + c_{15}^2}) + (c_{11} - c_{12} - 2c_{44})^2}).
\end{align*}
\]

Tetragonal (7) symmetry
\[
\begin{align*}
\frac{1}{2}((c_{11} + c_{12} + c_{33}) + \sqrt{8c_{13}^2 + (c_{11} + c_{12} - c_{33})^2}), \\
\frac{1}{2}((c_{11} + c_{12} + c_{33}) - \sqrt{8c_{13}^2 + (c_{11} + c_{12} - c_{33})^2}), \\
\frac{1}{2}((c_{11} - c_{12} + 2c_{44} + \sqrt{16(c_{14}^2 + c_{15}^2}) + (c_{11} - c_{12} - 2c_{44})^2}), \\
\frac{1}{2}((c_{11} - c_{12} + 2c_{44} - \sqrt{16(c_{14}^2 + c_{15}^2}) + (c_{11} - c_{12} - 2c_{44})^2), 2c_{44})
\end{align*}
\]

Tetragonal (6) symmetry
\[
\begin{align*}
\frac{1}{2}((c_{11} + c_{12} + c_{33}) + \sqrt{8c_{13}^2 + (c_{11} + c_{12} - c_{33})^2}), \\
\frac{1}{2}((c_{11} + c_{12} + c_{33}) - \sqrt{8c_{13}^2 + (c_{11} + c_{12} - c_{33})^2}), \\
\frac{1}{2}((c_{11} - c_{12} + 2c_{44} + \sqrt{16(c_{14}^2 + c_{15}^2}) + (c_{11} - c_{12} - 2c_{44})^2}), \\
\frac{1}{2}((c_{11} - c_{12} + 2c_{44} - \sqrt{16(c_{14}^2 + c_{15}^2}) + (c_{11} - c_{12} - 2c_{44})^2), 2c_{44})
\end{align*}
\]

\end{bmatrix}
$$

there for the case of isotropic symmetry. The first of (13) has been given in Gurtin [8] (p. 85) and, in the case of isotropic symmetry, by Villaggio [9] (p. 46). Toupin [1] and Gurtin [8] employ the terminology maximum elastic modulus for $\Lambda_i$ and minimum elastic modulus for $\Lambda_6$; see also [3] (p. 240). Kelvin [6] called the $\Lambda_i$, $i = 1, \ldots, 6$, the six principal elasticities of the material; Pipkin [10] uses the term “principal compliance” for the inverse of the same quantities; and Rychlewski [7] suggests, with persuasive historical justification (but contrary to the contemporary trend to avoid eponyms), that they be called the Kelvin moduli. Applications of the inequality represented by the first of (13), in the isotropic case, to obtain bounds for total energies and related quantities are described by Villaggio [9] (see, e.g., p. 400, 418).

In closing, we remark that the positivity of $\Lambda_i$, $i = 1, \ldots, 6$, is equivalent to the positive definiteness of $\Sigma$, expressed as a quadratic form in either $\bar{F}$ or $\bar{E}$. The explicitness of the eigenvalues tabulated in Table 1 here thus enables one to write down necessary and sufficient conditions for positive definiteness of $\Sigma$ directly in terms of the symmetric Voigt matrix $c$. The resulting conditions are...
simpler than the expressions involving principal minors of $e$ that are usually employed in the literature.
