| 13. ABSTRACT (Maximum 200 words) <p style="text-align: center;">The optimized geometry of 1, $C_2H_5-O-\overset{O}{\parallel}C-N(NO_2)_2$, a precursor to ammonium dinitramide, has been computed at the <u>ab initio</u> HF/6-31G* level. We find no structural evidence that 1 exists in the ionic form, $C_2H_5-O-C\equiv O^+ N(NO_2)_2^-$. The reaction of 1 with NH_3 passes through a transition state that is consistent with a concerted substitution (Ingold mechanism) in which $N(NO_2)_2^-$ is the leaving group.</p> | | | | | | | | | | | | | | | |

Introduction

Eq. (1) shows the final step in a synthetic route to ammonium dinitramide:

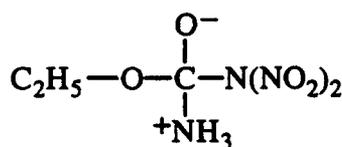

In this work, we have addressed two questions:

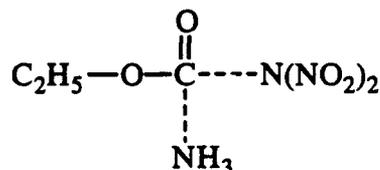

(1) Is there any evidence to indicate that **1** may actually be in the ionic form **1B**?

(2) Does eq. (1) proceed through the tetrahedral intermediate (or transition state) **3**, or is it a concerted substitution (Ingold mechanism) which goes through the transition state **4**, with $\text{N}(\text{NO}_2)_2^-$ being the leaving group?

3

4

Methods

All geometries were optimized at the *ab initio* HF/6-31G* level, using the GAUSSIAN 92 code [1]. The HF/6-31G* vibration frequencies were calculated for each structure, in order to determine whether it corresponds to a local energy minimum (zero imaginary frequencies) or to a transition state (one imaginary frequency).

Results and Discussion

Figure 1 shows our computed structure for **1**. It has no imaginary frequencies, confirming that it corresponds to an energy minimum. The C=O and C-N(NO₂)₂ distances are quite reasonable for these types of bonds at the HF/6-31G* computational level [2], and do not support

the idea that **1** may be in the form **1B**, for which one would anticipate an anomalously short C=O bond and long C-N(NO₂)₂. Furthermore, when we attempted to compute an optimized geometry for the cationic portion of **1B**, treating it as a separate entity, it broke up into CO₂ and C₂H₅⁺.

Our calculated structure for the transition state in eq. (1), formed by allowing NH₃ to interact with the central carbon in **1**, is given in Figure 2. It is indeed a transition state (not an intermediate), with one imaginary frequency corresponding to a vibrational mode involving the C-NH₃ and C-N(NO₂)₂ bonds. The bond angles around the central carbon are 100.6, 102.4, 117.0 and 125.1 degrees; these indicate a significant deviation from tetrahedral symmetry, for which they would all be 109.5°. In addition, the C=O distance (1.201 Å) is only 0.027 Å longer than in **1** and is quite compatible with this still being a double bond, whereas structure **3** suggests a single bond. On the other hand, the C-N(NO₂)₂ bond length has increased to 1.660 Å, compared to 1.450 Å in **1**. The C-NH₃ distance is almost as great, 1.615 Å. All of these results indicate that structure **4** is a better representation of the transition state than is **3**, despite many examples of nucleophilic interactions with carboxyl derivatives proceeding by tetrahedral mechanisms [3,4].

An interesting feature of the transition state is a hydrogen bond between an ammonia hydrogen (H₂₁) and a nitro oxygen (O₉), as indicated by the dashed line in Figure 2. The H₂₁...O₉ distance is 2.093 Å. For that nitro group, the N-NO₂ distance is 1.366 Å, which is less than the 1.414 Å - 1.423 Å range of the other N-NO₂ bonds in **1** and **4**. As the incipient C-NH₃ bond becomes shorter and stronger, H₂₁ may migrate to O₉, forming an isomer of dinitraminic acid which could subsequently react with a second NH₃ to give the product, ammonium dinitramide (**2**).
