PREPARERS AND CONTRIBUTORS

This project was completed by David Evans and Associates, Inc. (DEA) under contract with the Seattle District U.S. Army Corps of Engineers (Corps). Field work, data analysis, and report preparation were completed by Bret Forrester with support from Benn Burke. Thomas Duebendorfer provided plant identification assistance and additional field support. Andy Gorski acted as project manager for DEA and was responsible for quality control. Ronald D. Kranz served as principal-in-charge for DEA. Ken Brunner (Corps) served as project manager.

INTRODUCTION

Rufus Woods Lake is a 52-mile long reservoir created by the construction of Chief Joseph Dam in 1955. Rufus Woods Lake is in the Columbia Basin Province of north central Washington (Figure 1). The north bank lies within Okanogan County and the south bank within Douglas County. The shoreline is in a mix of private, state, federal, and tribal ownership. The Corps administers all but the uppermost six miles of the lake, which is administered by the U.S. Bureau of Reclamation.

The climate in the area is semi-arid with dry, hot summers and cold, dry winters. Average temperatures range from 78 to 90 degrees F in summer and 25 to 32 degrees F in winter. Average annual precipitation is approximately 10 inches, most of which occurs in winter as snowfall. The physiography in the vicinity of Rufus Woods Lake includes flat to moderately sloping terraces, rising either gently or abruptly to over 1,000 feet above the lake. The substrate consists primarily of basalt and granite. Shrub-steppe is the primary vegetation association that surrounds the lake. Sagebrush and grasses are the dominant vegetation. Other less common associations present include arid coniferous forest predominantly on north facing slopes and riparian zones dominated by deciduous trees and shrubs along perennial and seasonal water courses. These vegetation associations create a variety of wildlife habitats throughout the region.

Much of the land along Rufus Woods Lake is being utilized for agricultural purposes which has resulted in various levels of alteration to the native vegetation. Rangeland and orchard farming are the primary agricultural uses along the Lake. Grazing by livestock in rangeland areas has also resulted in the reduction of native plants and promoted the occurrence of non-native, weed species. Orchards and other crop production have eliminated all native vegetation in those areas. In 1981, the Seattle District of the Corps modified the Chief Joseph Dam project by raising the operating pool level by 10 feet. This project is referred to as the Chief Joseph Dam Additional Units Project and its implementation resulted in the inundation and elimination of approximately 100 acres of riparian habitat along the shores of Rufus Woods Lake. Pre-pool raise studies conducted by the University of Washington and the Washington Department of Fish and Wildlife (WDFW) provided information on the magnitude of these losses and recommended some methods of mitigation. Design memorandum (DM) 52, prepared by the Corps, documented habitat losses and proposed mitigation plans (Corps 1980). In response to agency concerns, the Corps implemented a mitigation program in 1982 and completed it in 1984. The mitigation program was designed to replace approximately 100 acres of riparian habitat lost to the pool raise by planting 100 acres of shrubs and trees, providing irrigation, and fencing the mitigation areas to exclude livestock, yet allow entry by native wildlife. In addition, approximately 530 acres of other land (mostly shrub-steppe) were fenced to exclude livestock and promote restoration and more productive conditions. The ultimate goal is to restore wildlife populations to numbers equal to those that existed prior to the pool raise. The primary target species are mule deer, Canada geese, bald eagles, and upland game birds. Other wildlife that benefit include non-game birds and mammals, and aquatic furbearers. DM 52 described a monitoring program that would be conducted on a five-year cycle for a duration of 25 years to evaluate the effectiveness of the mitigation project. The mitigation monitoring began in 1986 and continued through 1989. This report presents the findings from the second monitoring cycle which was conducted during the 1993/1994 season.

SHAPIRO & ASSOCIATES

AUTHORITY

Section 2(g) of the Fish and Wildlife Coordination Act of 1958 (Public Law 8-624) specifies mitigation requirements that apply to water projects. For the Chief Joseph Dam Additional Units Project, comprehensive baseline studies and a Habitat Evaluation Procedure (HEP) were used to assess the impacts and determine necessary compensation. DM 52 proposed a mitigation plan that was approved by higher authority and implemented. DM 52 requested technical site evaluation studies for 25 years to ensure that necessary adjustments in site management are accomplished to achieve initial project purposes. Representatives from the Corps, U.S. Fish and Wildlife Service (USFWS), WDFW, Colville Confederated Tribes (CCT), U.S. Forest Service (USFS), and the Soil Conservation Service (SCS) serve as an interagency group to evaluate the studies' findings and recommend changes in the operation and maintenance of the mitigation programs. This third study was funded by the U.S. Army Corps of Engineers.

OBJECTIVES

This monitoring study was designed to accomplish the following objectives:

- Determine the effectiveness of the mitigation components at meeting their intended goal. Specifically, did the plantings survive and grow as expected?
- Determine the effectiveness of the mitigation efforts. Specifically, do the newly created "riparian" habitats provide effective food and cover for wildlife? Are there any noticeable effects on wildlife populations as a result of the mitigation?
- Determine whether the mitigation program has any inherent or incidental problems or weaknesses, and whether simple solutions can be found to correct the problem(s).

DESCRIPTION OF MITIGATION SITES

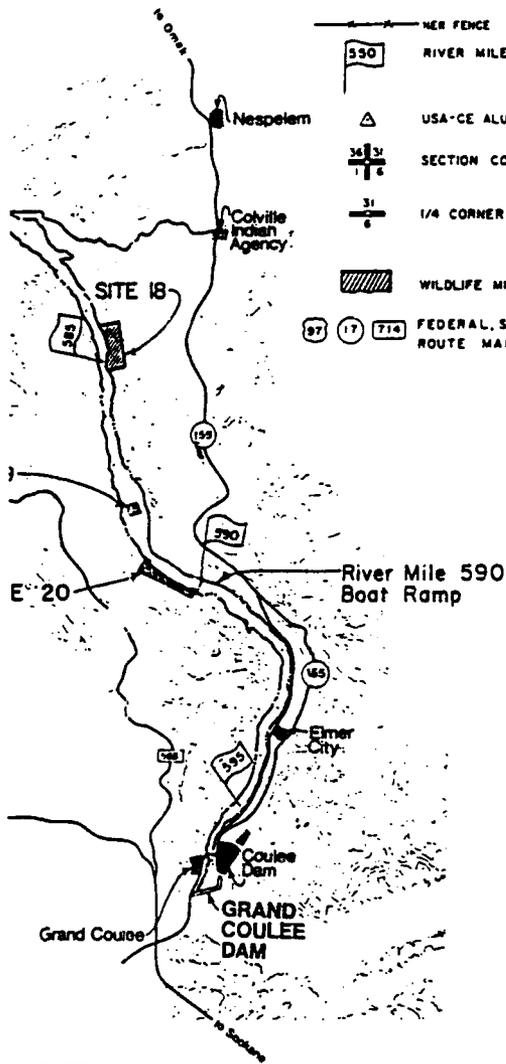

Mitigation is being accomplished through the operation of 16 constructed sites. Six are located on the north bank in Okanogan County and 10 on the south bank in Douglas County (Figure 2). Six of these sites (1, 3, 5, 11, 12, and 15) were irrigated in 1987 to support planted riparian shrubs and trees. Irrigation has been conducted each growing season since 1987 and is scheduled to continue for the duration of the project. These six irrigated sites and three additional sites (7, 8, and 18) have been fenced to exclude livestock while still allowing access to native wildlife. Sites 11 and 15 have been temporarily fenced to exclude deer until the sites recover from overbrowsing. Goose brooding islands and pastures have been developed at sites 10, 12, 16, and 18. Raptor poles were erected at five mitigation sites (3, 6, 7, 9, and 20) to replace inundated trees and snags, and goose nest tubs were installed at six sites (2, 3, 7, 10, 12, and 19).

LOCATION PLAN

**FIGURE 2
MITIGATION SITE
LOCATIONS**

Over the past ten years, six additional raptor poles were erected at sites 5, 7, 9, and 10, and ten additional goose nest tubs were installed at sites 1, 7, 10, 12, and 16. These additional features were not part of the initial mitigation design and are not evaluated under this contract.

Irrigation systems consist of well-head units that pump lake water to sprinkler heads. The sprinkler units distribute water in either a 100-foot or 140-foot radius, depending on the type of sprinkler head. Riparian habitat is being developed at all the irrigated sites. Trees, shrubs, and grasses have been planted within the irrigated portions of these sites.

Site 1 (Willows Draw) is located at river mile (RM) 551.5 on the south bank. The site is approximately 10 acres, 4.6 of which are irrigated. Five sprinkler heads are present. Adjacent landowners have erected fences to exclude deer from their orchards. This has limited, but not restricted, deer access to the site.

Site 2 (Goose Island) is located at RM 548 along the south bank. There are two goose nest tubs at this site where formerly there was a rock island prior to the pool raise.

Site 3 (Wells Flat) is an irrigated site located on the north bank in at RM 550. About 22.4 acres of the 45-acre site are irrigated with 12 sprinkler heads. There are three raptor poles and three goose nest tubs at this site. Deer fences around adjacent orchards substantially limit deer access to the site.

Site 5 (Arrowhead) is located at RM 553 on the north bank. About 18 acres of this 45-acre site is irrigated with 15 sprinkler heads. Similar to site 3, deer fences around adjacent orchards limit deer access to this site. The shoreline vegetation is maintained by the Corps by mowing to provide a goose brooding pasture.

Site 6 (China Knoll) is located at RM 554 on the south bank. Eight raptor poles are present on a bluff above the lake. This site is not fenced.

Site 7 (Box Canyon) is located on the south bank at RM 556. Approximately 210 acres have been fenced in two sections to keep livestock out. Three goose nest tubs and four raptor poles have been constructed at this site. A portion of the shoreline is mowed to create goose brooding pasture.

Site 8 (Turnwater Basin) is located on the north bank at RM 558. The site is five acres and is fenced to exclude livestock and protect a riparian draw.

Site 9 (Bryan Spring) is located at RM 557.5 on the north bank. Five raptor poles have been installed on the top of the hillside. The site is not fenced.

Site 10 (Lone Pine) is located on the south bank at RM 559. An island has been created at the downstream end of the site for goose nesting. Also part of this site, Lone Pine Island is a small rock island that is inundated at high pool level. Two goose nest tubs are mounted on Lone Pine Island.

Site 11 (Allen Bar) is a 62-acre irrigated and fenced site located on the south side of the lake at RM 562. Approximately 27 acres are irrigated with 24 sprinkler heads. This site has been fenced since 1986 to exclude deer until the shrubs can recover from previous overbrowsing.

Site 12 (Timm's Ranch) is located at RM 565 on the north bank. About 11.4 acres are irrigated by 15 sprinkler heads on this 31-acre fenced site. A goose brooding pasture has been established and two goose nest tubs have been erected on this site.

Site 15 (Alameda Flat) is located on the south bank at RM 574. About nine acres of this 28-acre site are irrigated. The site is permanently fenced to exclude livestock. Temporary fencing was added in late 1987 to exclude deer to prevent overbrowsing of mitigation plants.

Site 16 (Hopkins Canyon) is located at RM 576 on the north bank. Channels have been dug around a large rock outcropping to form a goose island. About 5.8 acres have been fenced for a goose brooding pasture.

Site 18 (Bailey Basin) is located along the north side at RM 585. Approximately 283 acres have been fenced to keep livestock out. A goose brooding pasture has been established. There are several riparian draws and a small wetland on the site.

Site 19 (Buckley Bar) is an island located near the south bank at RM 587. Two goose nest tubs have been installed on the downstream end of the bar.

Site 20 (Sanderson Creek) is located on the south side at RM 589. Five raptor poles have been installed on this site and it is not fenced.

METHODS

Between June 10, 1993 and March 17, 1994, the following monitoring has been conducted by DEA to evaluate the progress of the mitigation project:

- shrub and tree canopy coverage;
- forb/grass coverage;
- deer browse utilization;
- mule deer fawn surveys;
- upland game bird surveys; and
- other wildlife observations.

The remaining four monitoring tasks were conducted by the Corps. These tasks include the following:

- bald eagle surveys;
- bald eagle perch site surveys;
- raptor pole surveys; and
- Canada goose brooding surveys.

Vegetation Monitoring

The vegetation monitoring is composed of three monitoring tasks: (1) shrub and tree canopy coverage, (2) forb/grass coverage, and (3) deer browse utilization. A total of 110 permanent transects were previously established in four different community types on the mitigation sites: irrigated riparian, native riparian, bitterbrush, and big sage (Appendix A). Ten, 100-foot long transects were previously established in each of the three non-irrigated habitats. Eighty transects are located in the irrigated riparian areas with lengths ranging from 100 to 150 feet long, depending on the range of the sprinklers. The transects were established prior to the first monitoring session and are intended to be used for vegetation monitoring throughout the 25-year monitoring period.

The nature of the natural riparian vegetation in the project area (long and narrow), and the artificial nature of the irrigated mitigation sites (round), does not allow for control sites that can be compared with the mitigation sites. Thus, controls were established only for comparison with the bitterbrush, big sage, and native riparian habitats at the fenced shrub-steppe sites (sites 7 and 18). Control transects were established in bitterbrush, big sage, and riparian habitats at unfenced sites 6, 9, and 20. The comparison of the results from the control transects with the appropriate transects from the fenced shrub-steppe sites is intended to enable an evaluation of the effects of fencing.

Shrub and Tree Canopy Coverage. Line-intercept sampling methods, as described by Kaiser (1983) and conducted by Shapiro and Associates (Shapiro 1987), were used to determine canopy coverage for trees and shrubs along the 110 transects (Appendix A). Data were collected at eleven sites (1, 3, 5, 6, 7, 9, 11, 12, 15, 18, and 20). Each shrub and tree species that crossed an imaginary vertical plane above the transect was counted and its length along the transect recorded. Since all tree and shrub vegetative layers were recorded, coverage of more than 100% was possible when more than one species occupied the same segment(s) (overlapped) along the transects. Total coverage for each species, along each transect was calculated and combined to get the absolute average cover by site and/or habitat type. The goal of the mitigation plan is to achieve approximately 25 percent coverage of shrubs and trees at maturity (about 10-20 years for shrubs and longer for trees). Shrub and tree canopy coverage sampling was conducted from June 10 to July 1, 1993.

Forb/Grass Coverage. Quadrats 25 cm by 50 cm were placed at ten foot intervals on alternating sides of the 110 permanent transects (Appendix A). Sampling techniques were conducted following Barbour, et al. (1980) and Shapiro (1987). The percent cover for the three dominant species was estimated, unless fewer than three species were present. Data were collected at the same eleven sites (1, 3, 5, 6, 7, 9, 11, 12, 15, 18, and 20). Total coverage for each species, along each transect was calculated and combined to get the absolute mean average cover by site and/or habitat type. Forb/grass cover sampling was conducted from June 10 to July 1, 1993.

Deer Browse Utilization. Browse utilization was estimated using the methods described by Stickney (1966) and Shapiro (1989). The percentage of twigs browsed was determined by locating previously established random points along all but the big sage transects (two points on native riparian transects and one point on the remaining transects) (Shapiro 1987)(Appendix A). At every point, the nearest shrub was chosen in each of the four compass directions. The shrubs

observed were intentionally limited to red-osier dogwood (*Cornus stolonifera*), common snowberry (*Symphoricarpos albus*), currant (*Ribes* spp.), black hawthorn (*Crataegus douglasii*), western serviceberry (*Amelanchier alnifolia*), blue elderberry (*Sambucus cerulea*), smooth sumac (*Rhus glabra*), and Wood's rose (*Rosa woodsii*) since these species are known to be browsed by deer. Each shrub chosen was divided into quarters, and up to ten twigs were observed in each quarter, for a total of up to 40 leaders per plant. For any shrub with less than 40 twigs, all twigs were observed. The number of browsed and unbrowsed twigs were counted and recorded to estimate the percent of twigs browsed. Twig sampling was conducted from October 26 to 29, 1993, and again from March 15 to 17, 1994. The October survey was conducted after the plants had stopped growing and therefore, estimated deer browse during the previous spring and summer. The March survey was conducted before the plants began to grow and thus, estimated deer browse during the previous winter. Since no growth occurred between the surveys, evidence of summer browse was still present in March, therefore the October counts were subtracted from the gross spring counts to get the net percent browse from the winter months.

Wildlife Monitoring

Although the mitigation efforts are intended to benefit a wide variety of wildlife species, the wildlife monitoring plan emphasizes the primary target species: mule deer, Canada geese, bald eagles, and upland game birds. No specific surveys have been established for other species, however, all species of wildlife observed during the monitoring and their locations were documented. The monitoring surveys are not intended to estimate wildlife population numbers, rather they are intended to identify relative wildlife use of the mitigation sites and compare it to prior monitoring results. As stated above, DEA conducted only three of the seven wildlife monitoring tasks: (1) mule deer fawn surveys, (2) upland game bird surveys, and (3) observations of other wildlife.

Mule Deer Fawn Surveys. Four mule deer fawn surveys were conducted on eight sites (1, 3, 5, 7, 12, 18, 19, and 20). Two surveys were conducted in July and two in August 1993. Each site was walked by one biologist who began at one end of the site and investigated likely places where deer with fawns might bed down (i.e. areas that provide thermal or escape cover). A second biologist remained in the boat off-shore and observed the area around the on-site biologist in an attempt to spot any fawns out of sight from the on-site biologist. The two biologists maintained radio communication to assure that the same deer were not counted twice. The number of fawns observed were counted and fawn sign was documented when it was distinguishable from adult sign. The number and sex of adult deer observed were also noted.

Upland Game Bird Surveys. Six upland game bird surveys were conducted on six sites (1, 3, 5, 6, 11, 12, 15, and 18). One survey was conducted in July 1993, two in August 1993, and three in January 1994. One biologist, accompanied by a trained dog, followed the transects established by Shapiro (1987) (Appendix B). The number and species of game birds flushed were recorded. The dog was expected to cover approximately 50 feet of area on both sides of the transect (100-foot wide band). The dog used had previous experience flushing game birds and also showed a desire to locate birds.

The high survey counts of each species of game bird per site were totaled. Each species total was then divided by the number of acres surveyed (72.4) to get the total number of birds/acre.

This method of calculation is consistent with calculations made in earlier studies and was used to facilitate comparison of results. The intent is not to estimate the population levels of each species, but to derive a population index for each species that can be used to compare relative levels of site use during different seasons and years.

Other Wildlife Observations. No separate surveys were conducted for other wildlife. However, all species identified during other surveys, as well as their locations, were documented and presented in this report. These observations were made at varying times and durations depending on the size and extent of other tasks performed on-site. Because of this variability in observation effort, wildlife presence data is not comparable between sites and can not be used to estimate relative levels of wildlife use.

RESULTS

Vegetation Monitoring

Table 1 presents the results of the vegetation monitoring that was conducted along the previously established 80 irrigated transects and 30 non-irrigated transects (Shapiro 1987)(Appendix A). 124 plant species were identified by DEA in and around the mitigation sites during this study. The common and scientific names of these plants are presented in Appendix C.

Shrub and Tree Canopy Coverage. Shrub and tree canopy coverage sampling was conducted from June 10 to July 1, 1993. The average total coverage for the irrigated sites was 55.3 percent (Table 1). This compares to 10.6 percent coverage estimated by Shapiro (1987). Shrub and tree coverage has increased 44.7 percent on the irrigated sites in the last seven years. Coverage in 1993 (eleventh year of the project) was 30.3 percent greater than the mitigation goal of 25 percent at the tenth year. Coverage on the irrigated sites ranged from a low of 32.7 percent at site 11 to 93.3 percent at site 3 (Table 1).

In general, the shrub plantings on the irrigated sites tend to be concentrated near the center of the mitigation circles and the trees occur toward the perimeter. This planting pattern was necessary to allow plant compatibility with the pattern of spray from the sprinklers. In numerous locations where trees have not been planted far enough from the center of the site (sprinkler head), the stream of water from the sprinklers have sheared off the tops of the trees.

Although shrub and tree coverage is relatively sparse on some transects (primarily at site 11), the majority of the plantings are dense and prolific. Many shrub species are reproducing (primarily Wood's rose) and most trees are flowering and producing seeds. Tree height is generally consistent between irrigated sites with the average height estimated between 20 and 30 feet.

Table 1: Comparison of Shrub and Tree Monitoring Results on Irrigated Sites (expressed in average percent cover)

Site	Number of Transects	1987*	1993	Difference
1	5	12.0 %	77.0 %	65.0 %
3	12	16.6 %	93.3 %	76.7 %
5	15	15.7 %	61.3 %	45.6 %
11	24	6.8 %	32.7 %	25.9 %
12	15	9.8 %	57.9 %	48.1 %
15	9	5.9 %	38.9 %	33.0 %
Total	80	10.6 %	55.3 %	44.7 %

* Shapiro 1987

Although coverage and vitality of shrub and tree mitigation plantings is generally high, invasive shrubs, primarily Himalayan blackberry, have established at most irrigated sites. Himalayan blackberry was documented along 28 of the 80 irrigated transects. Given the invasive nature of Himalayan blackberry, it may likely outcompete the surrounding mitigation plants if its presence is permitted. Such invasion has already taken place at most of the irrigated circles at sites 1 and 12. Large growths of Himalayan blackberry have also established at least one irrigated circle on the remaining irrigated sites (sites 3, 5, 11, and 15). Other, invasive weeds (e.g. sweet clover [*Melilotus* spp.], mullein [*Verbascum thapsus*]) also occur regularly around the outer perimeter of most irrigated circles, outside of the area sampled by the transects.

Overall coverage for the fenced big sage transects was 41.6 percent, an 18.2 percent increase from the 1987 study (Table 2). Unfenced sites also had an increase (7.4 percent) in big sage coverage. Big sage is present in all age classes on both fenced and unfenced sites. Small plants are present, thus indicating reproduction on all sites. No significant difference between the fenced and unfenced big sage transects is noticeable following the shrub and tree coverage results.

Coverage along bitterbrush transects on the fenced sites increased 7.6 percent from the 1987 study to an average of 42.1 percent coverage. Coverage along unfenced bitterbrush transects increased 27.1 percent to a total of 49.9 percent. Bitterbrush plants on site 6 (unfenced) are typically large, old individuals with sparse vegetation on the lower portions of most plants. Small bitterbrush plants are uncommon on site 6, thus indicating low regeneration. Small plants are more common on the remaining sites, but large, old bitterbrush are most common. Compared to the big sage transects, bitterbrush reproduction appears to be less successful on both the fenced and unfenced sites.

Table 2: Comparison of Shrub and Tree Monitoring Results on Non-Irrigated Sites (expressed in average percent cover)

Site	Number of Transects	1987*	1993	Difference
Big Sage				
Fenced (7 & 18)	5	23.4 %	41.6 %	18.2 %
Unfenced (6, 9 & 20)	5	16.1 %	23.5 %	7.4 %
Bitterbrush				
Fenced (7 & 18)	5	34.5 %	42.1 %	7.6 %
Unfenced (6, 9 & 20)	5	22.8 %	49.9 %	27.1 %
Riparian				
Fenced (7 & 18)	5	91.9 %	131.7 %	39.8 %
Unfenced (9 & 20)	5	89.1 %	108.8 %	19.7 %

* Shapiro 1987

The fenced native riparian transects increased 39.8 percent to an average coverage of 131.7 percent. Unfenced native riparian transects also displayed an increase in cover of 19.7 percent to yield an average of 108.8 percent cover. Transects R-1 and R-2 in the unfenced native riparian habitats on site 20 were virtually barren of shrub and tree vegetation throughout the lower strata, but were generally dense in the upper layers above about four feet. Because of the sampling procedures, the shrub and tree sampling results did not indicate the stratified vegetation. This sparse lower strata is apparently a result of livestock presence on this site. The two unfenced riparian transects on site 9 (R-1 and R-2) and R-3 on site 20 are located in steep sided and/or steep narrow draws that appear to be largely inaccessible to cattle. Accordingly, the shrub and tree vegetation along these transects is dense throughout all strata. Although these sites are unfenced, the presence of livestock may not have an impact in these areas because of the relatively inaccessible locations.

Forb/Grass Cover. Forb/grass cover sampling was conducted from June 10 to July 1, 1993. The average total coverage for the irrigated sites was 101.4 percent (Table 3). This compares to 70.6 percent coverage estimated by Shapiro in June 1986 (Shapiro 1987). Forb/grass coverage has increased 30.8 percent on the irrigated sites in the last seven years. Bare areas most often

only occur below dense shrub and tree canopies. Hard fescue (*Festuca ovina*) was the dominant species at all irrigated sites. Coverage of hard fescue ranged from 78.0 percent at site 1 to 93.1 percent at site 11. The remaining forb/grass species coverage was less than 10 percent at all sites except 15 where sweet clover (*Melilotus* spp.) had an average coverage of 16.1 percent.

Table 3: Comparison of Forb/Grass Monitoring Results on Irrigated Sites (expressed in average percent cover)

Site	Number of Transects	1987*	1993	Difference
1	5	85.4 %	104.3 %	18.9 %
3	12	70.3 %	94.2 %	23.9 %
5	15	64.7 %	99.4 %	34.7 %

Total	80	70.6 %	101.4 %	30.8 %

* Shapiro 1987

Forb/grass cover increased 42.8 percent since 1987 to a total of 105.3 percent on the fenced big sage transects (Table 4). Cheatgrass (*Bromus tectorum*) was the dominant species with 60.7 percent coverage (43 occurrences). All other forb/grass species had less than 6 percent cover. Unfenced big sage transects yielded 57.6 percent forb/grass coverage, an increase of 13.8 percent over the 1987 survey. Cheatgrass at 17.0 percent coverage (20 occurrences) was also the dominant. All other forb/grass species on the unfenced big sage transects had less than 9 percent cover.

Forb/grass cover increased 20.9 percent since 1987 to a total of 64.6 percent on the fenced bitterbrush transects (Table 4). Cheatgrass was the most common species with 28.9 percent coverage (39 occurrences). Needle-and-thread grass (*Stipa comata*) was second most abundant with 20.4 percent coverage (23 occurrences). Unfenced bitterbrush transects yielded 82.8 percent forb/grass coverage, an increase of 21.3 percent over the 1987 survey. Cheatgrass at 38.1 percent coverage (41 occurrences) and needle-and-thread grass at 10.1 percent coverage (15 occurrences) were also the dominant species.

Table 4: Comparison of Forb/Grass Monitoring Results on Non-Irrigated Sites (expressed in average percent cover)

Site	Number of Transects	1987*	1993	Difference
Big Sage				
Fenced (7 & 18)	5	62.5 %	105.3 %	42.8 %
Unfenced (6, 9 & 20)	5	43.8 %	57.6 %	13.8 %
Bitterbrush				
Fenced (7 & 18)	5	43.7 %	64.6 %	20.9 %
Unfenced (6, 9 & 20)	5	61.5 %	82.8 %	21.3 %
Riparian				
Fenced (7 & 18)	5	54.1 %	76.0 %	21.9 %
Unfenced (9 & 20)	5	49.2 %	83.1 %	33.9 %

* Shapiro 1987

The fenced riparian areas had a forb/grass cover increase of 21.9 percent over the 1987 results (Table 4). Total coverage was 76.0 percent compared to 54.1 percent in 1987. Star Solomon's seal (*Smilacena stellata*) was the dominant species with 23.0 percent cover (21 occurrences). The remaining forb/grass species all had less than 10 percent coverage along the fenced riparian transects. The unfenced riparian areas had 83.1 percent coverage, an increase of 33.9 percent over the 1987 results. The dominant species were Idaho fescue (*Festuca idahoensis*) with 16.1 percent coverage (9 occurrences) and giant wildrye (*Elymus cinereus*) with 14.0 percent coverage (8 occurrences).

Deer Browse Utilization. Deer browse utilization was sampled October 26 through 29, 1993 (fall) and again from March 15 through 17, 1994 (spring). Fall results showed an average decrease in use of 5 percent on the irrigated sites in comparison with the fall 1987 results (Shapiro 1989) (Table 5). However, the Shapiro study surveyed site 15 in the fall which had 47.7 percent browse utilization, whereas site 15 was not surveyed during the 1993/1994 study because it was fenced in late 1987 with a deer fence, and the fence still remains. Site 12 had the greatest fall browse utilization at 19.9 percent and site 1 had the lowest utilization at 3.9

percent. Red-osier dogwood and black hawthorn had the highest fall browse utilization at 27.7 percent and 22.0 percent respectively (Table 6).

**Table 5: Comparison of Deer Utilization of Shrubs
(expressed in percent of twigs browsed)**

Site	1987 Study ¹	1989 Study ²		1994 Study

bitterbrush	6	39.2 %	27.5 %
Bitterbrush			
bitterbrush	48	46.0 %	12.4 %

Spring results on the irrigated sites show a 6.8 percent decrease in deer browse utilization below the spring 1988 study results. Browse results on the irrigated sites ranged from a high of 6.5 percent on site 1 to a low of no browse detected on site 12. Western serviceberry and bitterbrush had the highest browse results on the irrigated sites at 5.7 percent and 5.0 percent, respectively. The remaining species had 2.0 percent or less.

The non-irrigated riparian shrubs sampled during the fall 1993 survey had a 28.6 percent average utilization, a 13.3 percent increase over the fall 1987 results (Shapiro 1989). Black hawthorn, bitterbrush, and red-osier dogwood had the highest fall deer browse use at 42.7 percent, 39.2 percent, and 38.4 percent respectively.

The 1994 spring results on the native riparian transects were 0.2 percent lower than in 1988. Bitterbrush had the highest ratio of browse at 27.5 percent. The next greatest was western serviceberry at 10.2 percent. The remaining species had less than 2.0 percent browse.

The bitterbrush transect results indicate fall browse utilization of 46.0 percent, a 35.0 percent increase over the fall 1987 results. Spring results on the bitterbrush transects decreased 5.6 percent over the 1988 spring results for a total of 12.4 percent.

If the 1987 results from site 15 are omitted, the fall browse results from the irrigated sites for 1987 and 1994 are about the same. The fall results increased in 1994 on the non-irrigated sites. Spring results generally decreased on the irrigated and bitterbrush sites in 1994. Spring browse results from riparian areas were nearly the same in both years.

Wildlife Monitoring

Mule Deer Fawn Surveys. A total of 12 mule deer fawns were observed during the surveys on the specified sites (Table 7). Seven of these sightings were on site 7. Ten occurred on non-irrigated sites (sites 7, 18, and 19) and two on irrigated site 5.

Table 7: 1993 Mule Deer Fawn Survey Results

* = one dead fawn found

Fewer fawns were observed in 1993 compared to past surveys conducted in 1987 and 1988 by Shapiro. In the 1987 survey, high counts of fawns observed during fawn surveys totaled 28, however, all were counted on one site (site 7) (Table 8). Total of high counts from the 1988 survey was 33. Fawns were observed on four different sites (sites 1, 6, 7, and 12) in 1988, but 29 of the observations were made on site 7. High counts from the 1993 surveys totaled 11 fawns which were observed on four different sites (sites 5, 7, 18, and 20). Six were observed on site 7. Eight of the 12 fawn sightings (67 percent) were from the Douglas County (south) shoreline. In the 1987 survey, 100 percent of the fawns were observed along the Douglas County (south) shoreline and 98 percent during the 1988 survey.

Each year a different combination of mitigation sites were surveyed, therefore, a direct comparison can not be made for the entire survey. Fewer fawns were observed on site 7 during the 1993 survey than during the prior two surveys. A high count of four fawns were observed on site 7 in 1993 compared to a high of 19 during the 1988 survey and 15 during the 1987 survey. The remaining sites surveyed counted two or less fawns during each survey during the 1987, 1988, and 1993 studies. Because of the small number of fawns observed per site, a trend in fawn presence can not be determined with confidence.

NS = site not surveyed

Overall deer counts (fawns and adults) were lower during the 1993 surveys than in the previous surveys. As with the fawn counts, by far the most deer were observed at site 7, but less than in previous surveys. Deer or deer sign was observed at all sites visited by DEA in 1993 and 1994.

Upland Game Bird Surveys. Results of the summer upland game bird surveys are presented in Table 9. Tables 10 and 11 illustrate comparisons of results of past summer upland game bird surveys with the 1993 survey results. By comparison with the summer 1987 and 1988 surveys, chukar, gray partridge and mourning dove sightings decreased significantly and ring-necked pheasant and California quail sightings slightly increased (Table 10). No chukars or gray partridges were observed on any mitigation site during the summer 1993 surveys. The increase in the number of pheasant and quail sightings was slight and may not be statistically significant. This is probably most true for the quail sightings which were all made at one time on site 18. All the pheasant sightings were made on sites 3 and 5. High counts of 3 to 10 mourning doves were made on all sites surveyed except site 6 which had a high count of 47 (Table 11). Ring-necked pheasants were sighted with some regularity on sites 3 and 5 and mourning doves were regularly sighted on all the surveyed sites (Table 9).

Results of the winter upland game bird surveys are presented in Table 12. Tables 13 and 14 illustrate comparisons of results from past winter upland game bird surveys with the 1994 survey results. In 1994 there were considerably fewer chukar partridges sighted and significantly more ring-necked pheasants sighted (Table 13). California quail were observed during the 1994 surveys, but were not observed in previous winter surveys. However, as with the summer quail sightings, the quail were observed only one time in one location. There was a slight decrease

in mourning dove sightings. As with the 1988 survey, mourning doves were observed only on site 12 during the winter survey (Table 12). Ring-necked pheasants were sighted consistently and usually in relatively large numbers (compared to other mitigation sites) on site 3 and to a lesser degree on site 5. All other winter sightings were sporadic and unpredictable. Shotgun shell casings were commonly observed on mitigation sites 3 and 5 which could be further indication of higher game bird densities.

Other Wildlife Observations. A total of 65 species of birds were documented during the breeding season through casual observations in the vicinity of Rufus Woods Lake (Appendix D). Of these, 62 species were documented on or along the immediate shoreline of the 12 mitigation sites (1, 3, 5, 6, 7, 9, 11, 12, 15, 18, 19, and 20) visited during other surveys. Fourteen species (mourning dove, northern flicker, eastern kingbird, cliff and northern rough-winged swallows, American robin, cedar waxwing, yellow warbler, western meadowlark, red-winged and Brewer's blackbirds, northern oriole, western tanager, and American goldfinch) were commonly observed on the irrigated sites during the breeding season. In contrast only four species (mourning dove, eastern kingbird, western meadowlark, and Brewer's blackbird) were commonly observed birds on non-irrigated sites during the breeding season. Other noteworthy species observed on mitigation sites during the breeding season include black-crowned night heron (juvenile) on site 12, Lewis woodpecker on site 20, loggerhead shrike on sites 1, 3, 6, and 11, warbling vireo on sites 1 and 11, MacGillivray's warbler on sites 1 and 5, yellow-breasted chat on sites 18, 3, 5, and 12, and a lazuli bunting on site 15.

Bald and golden eagles, osprey, red-tailed hawk, and American kestrel were all observed perching on raptor poles at various times and locations. Bald eagles were observed primarily upstream from RM 580 (near the confluence of the Nespelem River) during the breeding season. One active bald eagle nest was observed on the south shore at about RM 582. Wintering bald eagles were not concentrated in any particular portion of the reservoir. Two golden eagle nests were observed one at RM 553 and one at RM 588. One active osprey nest was present in a snag near the shoreline at site 18 and one active red-tailed hawk nest was located in a ponderosa pine along the shoreline near the west end of site 20. Other raptors observed include northern harrier, turkey vulture, great-horned owl, and barn owl.

Observations of 79 different bird species were made throughout the year in the vicinity of Rufus Woods Lake. Mitigation site 12 (irrigated) had the highest number (37) of bird species observed (Appendix D), followed by site 5 (irrigated) with 34, site 18 (non-irrigated) with 31, site 11 (irrigated) with 29, site 3 (irrigated) with 28, site 1 (irrigated) with 23, and site 7 (non-irrigated) with 20. The remaining irrigated site (site 15) and four non-irrigated sites (sites 6, 9, 19 and 20) had under 20 bird species documented during this study.

During the 1987 study, a high count of 29 bird species occurred on site 18 (Shapiro 1987). During the 1987 and 1989 studies conducted by Shapiro, more time was spent on the mitigation sites because transects were set up, and more wildlife studies were conducted; therefore, more time was available to making bird observations. If this is true, the casual observations from this study indicate a trend toward more species use on the irrigated sites. These results must be considered with caution since these were not controlled surveys, but rather casual observations with varying levels of intensity between sites.

A total of 13 mammal species were observed, or their sign was detected, in the vicinity of Rufus Woods Lake (Appendix E). Ten species were documented on non-irrigated sites and nine on irrigated sites. Coyote, mule deer, and vole were the most common mammals documented and evidence of their presence occurs on nearly all the mitigation sites visited during this study. Badger sign was observed on five sites (7, 18, 20, 3, and 12). Black bear sign was documented on five sites (18, 20, 3, 5, and 12) and a sow and cub were observed on the north bank adjacent to Lone Pine Island at RM 559. Beaver and their sign were observed on sites 18 and 20, and

evidence of beaver presence was observed on irrigated sites 3 and 5. The beaver have felled numerous mitigation trees, often the largest trees, on sites 3 and 5. Other wildlife damage to mitigation plantings was caused by porcupines. Porcupines were observed on sites 11 and 18 and evidence of porcupines was observed on site 15. On the irrigated sites (11 and 15) porcupines have stripped the bark from portions of numerous mitigation trees, primarily ponderosa pine and Russian olive.

Western rattlesnakes were observed on non-irrigated sites 6 and 18. Racers were seen on sites 6 and 7 (non-irrigated) and site 11 (irrigated).

CONCLUSIONS

Vegetation

Irrigated Sites. The overall average canopy coverage of trees and shrubs on the irrigated sites is 55.3 percent, 30.3 percent greater than the mitigation goal of 25 percent canopy coverage at plant maturity (10-20 years for shrubs and longer for trees). These results indicate that the overall coverage goal has been achieved ahead of schedule, as predicted by Shapiro and Associates (1989). Each individual irrigated site also has an average canopy coverage greater than the 25 percent goal, but 10 transects on site 11 and one transect on site 15 were below 25 percent coverage. These transects probably are representative of the past overbrowsing by deer that took place on these sites. The fencing that has been erected to keep deer out appears to be effective in reducing deer browsing on these sites considering the substantial increase in coverage since the last monitoring, however, deer were observed on both sites during this monitoring period.

Because of the shearing effect of the sprinklers, the taller growing trees such as ponderosa pine, may not be able to achieve their natural height and structure. Such restrictions in growth may eliminate the potential for these normally taller growing trees to provide suitable habitat for species that rely on such structure (e.g. nest and perch sites for raptors, foraging and nest sites for woodpeckers and other cavity nesting birds).

Overall forb/grass cover is 101.4 percent for the irrigated sites. This is an increase of 30.8 percent since the last survey. Bare ground typically only occurs in shaded areas below dense shrubs and trees which are common along most transects. The forb/grass establishment on the irrigated sites has established successfully on all sites. Invasive herbaceous weeds such as sweet clover and mullein are the only concern related to groundcover on the irrigated sites. Other invasive weeds, primarily Himalayan blackberry, could significantly limit the spread of mitigation plants and even eradicate them in some areas. Himalayan blackberries have established most at sites 1 and 12.

Non-irrigated Sites. Shrub and tree growth along all non-irrigated transects increased since the last monitoring. Increases at fenced sites were not significantly greater than at unfenced control sites. However, the influence of cattle is apparent on riparian transects R-1 and R-2 at site 20 where shrub and tree foliage is virtually non-existent below four to five feet height, but the survey results did not detect such influences by domestic stock. The remaining control (unfenced) riparian sites typically occur on steep gradients or have steep sided channels that appear to be largely inaccessible to cattle, which could be why significant differences are not detectable in the native riparian shrub and tree survey results.

The average cover of forb/grass species along non-irrigated transects indicates only a slight difference between fenced and unfenced sites. Average forb/grass cover is 82.0 percent at fenced sites, compared to 74.5 percent at unfenced non-irrigated sites. Since cattle are grazers and not browsers, it is logical that the herbaceous coverage is less on the unfenced sites, although this slight difference suggests only minor benefits from fencing. Livestock use may be light in the unfenced areas, which would explain this slight difference in herbaceous coverage. Furthermore,

no significant difference in species composition is notable along the forb/grass transects and cheatgrass is the dominant species on all fenced and unfenced bitterbrush and big sage transects. Perhaps more time is needed before significant differences between fenced and unfenced non-irrigated sites are detected in the herb/grass vegetative layer.

Deer Browse Utilization. On a site-to-site comparison of fall survey results for deer browse utilization, the non-irrigated riparian and bitterbrush sites received the most browse, thus indicating greater deer use in these areas. Compared to the fall results, the spring results were substantially lower on all sites. The bitterbrush transects had the highest level of spring browse. Bitterbrush, red-osier dogwood, black hawthorn, and western serviceberry had the highest levels of browse overall.

Conclusions from these comparisons of deer browse could be misleading for a number of reasons. Annual fluctuations of deer populations would likely result in a change in the level of deer browse at a particular site, but the site may be equally attractive (or-unattractive) to deer for browsing. The WDFW estimated a 30 to 35 percent winter kill of deer in the Chief Joseph area in 1992/1993. Climate, as it affects vegetative growth and nutrition of individual plant species, could also cause a shift in deer browse preference. Also, shrubs at many of the twig points appear inaccessible to deer due to dense surrounding growth.

Many possible inaccuracies in survey results could occur from the browse survey methods used. The methods used to evaluate browse use do not take into consideration a change in browse availability, and thus render incomparable results between survey years. For example: more browse could take place on a given site in one year than a previous year, but if there is a greater amount of browse available due to increased plant growth, the ratio of browsed twigs to unbrowsed twigs could be lower than in the previous study. A direct comparison of browse ratios between seasons or survey years is only meaningful if there are equal amounts of available browse during each survey. Given the substantial increase in shrub and tree canopy coverage on the irrigated sites, this skewing of results could likely have occurred on those sites.

The spring browse survey results could be further affected resulting from the difficulty of detecting browse on some plants during that time of year. Because smooth sumac and blue elderberry shed their leaves and only relatively large woody stems remain it is unlikely that these species offer much potential browse in that condition and it is not possible to detect browse that was evident in the fall. This also occurs on any plants that portions (such as limbs) die off over the winter. Common snowberry is particularly difficult in determining browse in the spring because the end twigs are fine and brittle and difficult to determine if they are dead or alive, or browsed or broken. The currant were sprouting leaves and buds at the time of the survey in mid-March which creates further inaccuracies when calculating winter browse. The sample sizes for smooth sumac, currant, and blue elderberry were probably too low to be statistically significant.

Because of the numerous variables that could affect the browse survey results, an accurate quantitative comparison of browse utilization is probably not possible. The results probably best indicate that the mitigation sites are providing browse for deer, and that deer browsing occurs throughout the year.

Wildlife

Mule Deer Fawn Surveys. Because of the small sample size (two or less) of fawns counted on all sites but site 7 during the 1987, 1988, and 1993 surveys, these results are probably not comparable. Additionally, sites 6, 15, 18, and 20 were surveyed during only one of the three survey years. Fewer fawns were sighted on site 7 during the 1993 survey than in the 1987 and 1988 surveys. Assuming that the habitat quality has not significantly degraded in any way on site 7 (the vegetation monitoring does not indicate significant degradation), other reasons for lower numbers of fawns on the site could be in effect. Unseasonably cool summer weather could have influenced the deer presence during the fawn surveys. The deer may not have relied on the riparian areas as much as during a typically warmer and drier summer and as a result may not have been as concentrated along Rufus Woods Lake. Also, a natural fluctuation in the mule deer population could have resulted in fewer deer in the project vicinity. As stated above, the WDFW estimated a 30 to 35 percent winter kill of deer in the Chief Joseph area in 1992/1993. Since the duration of surveys on each site were not reported by Shapiro (1987 and 1989), the level of effort between study years may not have been consistent. Also, observer differences could have contributed to different deer counts.

Upland Game Bird Surveys. The upland game bird surveys suggest a trend toward fewer chukar partridge and more ring-necked pheasant occupying the mitigation sites. Pheasant presence is apparently increasing on the irrigated sites, especially sites 3 and 5. Chukar observations declined on all sites except site 1 during the winter survey. The apparent chukar decline on the irrigated sites could be attributed to the conversion of rocky, grassy, and brushy arid slopes (chukar habitat) to riparian habitat. The chukar decline and pheasant increase on the irrigated sites may be an indication that the creation of simulated riparian habitat is being accomplished. Estimated summer densities of mourning doves declined in 1993 which could be due to natural population decline or changing habitat conditions. The estimated densities for the remaining upland game birds (California quail, ruffed grouse, and gray partridge) are either too low or the density differences between monitoring years are too minor to make any conclusions about population trends.

In general, lower than expected game bird detections probably occurred on the irrigated sites due to vegetation structure. The substantial increase in tree and shrub growth on the irrigated sites over past survey years impeded game bird detection at some times during this survey. The vegetation is so dense in many areas that it was difficult to follow the established survey transects. The dense and tall vegetation often made it difficult to spot, identify, and count flushed birds. Missed sightings are also suspected to have occurred as a result of the dense, short vegetation. In many locations the dense shrub vegetation noticeably restricted dog movement, thus resulting in a smaller survey area and fewer sightings.

Other Wildlife. The irrigated mitigation sites appear to be providing habitat during the breeding season for a wider variety of non-game birds than in previous years. Although no specific goals were established for non-game birds, the mitigation sites appear to have created suitable habitat conditions for many species associated with riparian habitats. Mammal species identified on the mitigation sites are generally the same as identified during the 1989 study (Shapiro).

RECOMMENDATIONS

Vegetation

Since the mitigation plants at the irrigated sites have prematurely accomplished the canopy coverage goal, no significant modifications to the maintenance and operation of these areas are warranted. Only the periodic removal of Himalayan blackberry and other invasive weeds are recommended to prevent the reduction of mitigation plant diversity and cover.

Wildlife

Because wildlife populations are dynamic and continually fluctuate, and because the mitigation surveys are scheduled to be conducted only once every five years, a long-term approach should be incorporated when evaluating wildlife use at the mitigation sites. Determination of mitigation success/failure should not be based on results from a single monitoring season. Results from several monitoring seasons should be evaluated to identify wildlife presence and use trends on mitigation sites. Also, the following modifications or changes in wildlife survey methodologies should be considered.

The adoption of a different browse utilization methodology is recommended to eliminate the incomparable results that occur when vegetation growth (browse availability) substantially changes. A technique may be able to be developed that factors in the vegetation monitoring data and correlates it to the browse results to get a relative amount of browse per site rather than a percent of available twigs browsed.

Also, common snowberry, smooth sumac, currant, and blue elderberry could be eliminated from the browse survey because these species yield less reliable results than the other monitored shrubs due to their low sampling frequency and difficulty in detecting browse on these plants, especially in the spring. Only the more prevalent species with the most reliable detection of browse that receive the greatest level of deer use (red-osier dogwood, bitterbrush, western serviceberry, Wood's rose, and possibly black hawthorn) should be surveyed for browse. By surveying these species only once in the early spring to determine relative levels of browse for an entire year, results would be more accurate and monitoring costs would be reduced.

As suggested by Shapiro (1989), transect locations for future upland game bird surveys on the irrigated sites should be rerouted through areas that can be accessed by future surveyors. The new transect alignments should be the same length as the present transects so that equal areas are surveyed. Although this should help keep the area surveyed equal, the possibility of missed sightings is expected to continually increase as the plants mature.

The duration of mule deer fawn survey site visits should be specified to enable consistent levels of effort in surveys. Mule deer fawn survey techniques should also be standardized so that the same methods are used during each monitoring season.

Since a relatively large number of species of non-game birds are associated with all habitat types in the project vicinity, their presence is a good indicator of the quality of a given habitat. The

casual survey results suggest that non-game birds are increasing on the irrigated mitigation sites. Non-game bird surveys could be incorporated into the monitoring program to provide comparative indices of non-game bird use on the mitigation sites. Timed bird censuses conducted during the nesting season could be performed at random points, in all habitat types, on each site. This would eliminate the bias caused from casual observations when unequal time is spent on different sites and could provide another quantitative index to evaluate mitigation success.

SUMMARY

Given the results of the vegetation, summer deer browse, and winter upland game bird surveys, and non-game observations, DEA feels that the mitigation goals are being met. The objectives for the mitigation program established in DM 52 have apparently been achieved. The plantings are generally in good health and have grown faster than expected. Overall tree and shrub vegetation coverage easily exceeds the goal of 25 percent. The mitigation project appears to have successfully provided roughly 100 acres of artificial riparian habitat that are being utilized by a variety of wildlife species.

Evidence of use by a variety of wildlife was consistently observed through casual observations. Although results from mule deer fawn surveys and summer upland game bird surveys were lower than in previous years, winter upland game bird results generally increased and browse results were comparable to previous surveys. The need to fence sites 11 and 15 to exclude deer is further evidence that the irrigated sites are attracting wildlife.

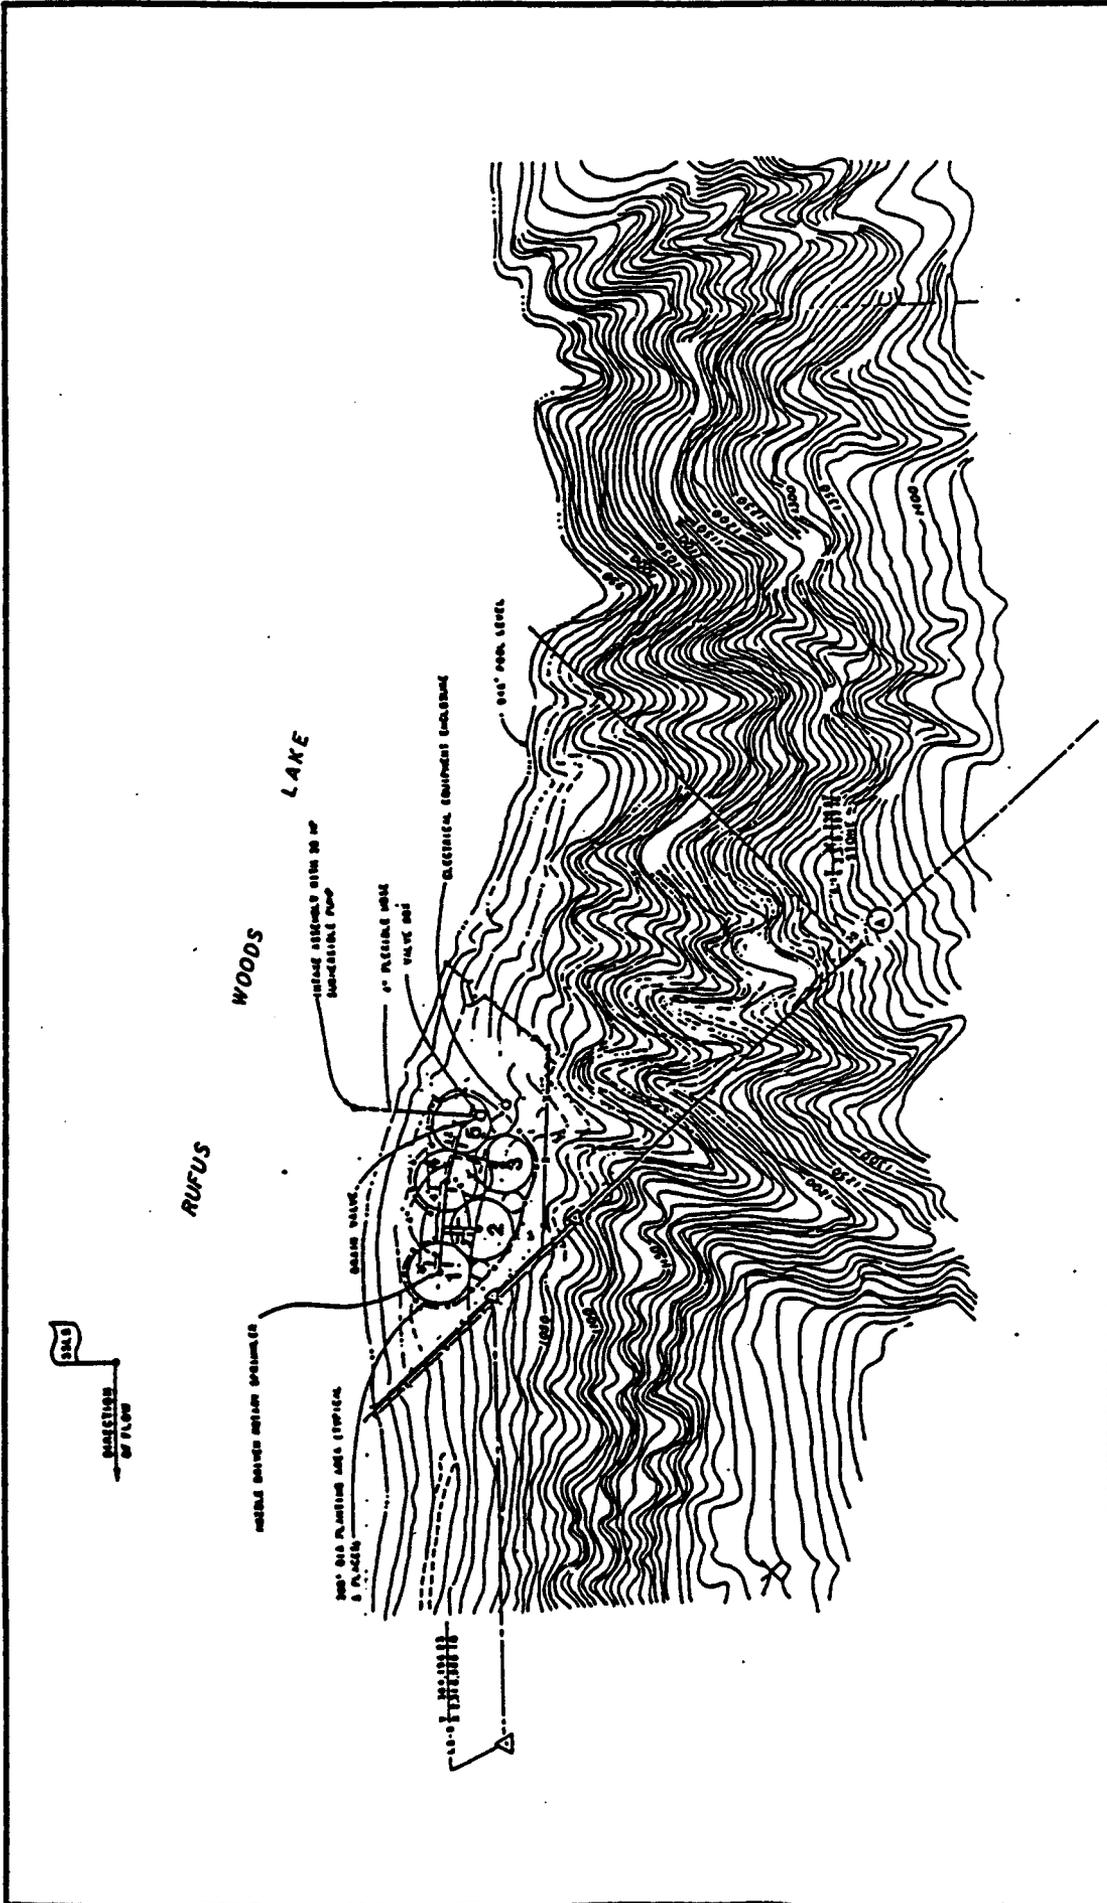

Numerous factors such as population fluctuations, climate variations, methodology limitations, and monitoring inconsistencies are likely reasons for inconsistent or inaccurate results. By evaluating the mitigation project's success over the long-term, short-term downward fluctuations in wildlife populations will likely be "averaged out" over time. Modifications to sampling or analysis techniques would likely eliminate much of the potential bias in survey results for deer browse and upland game birds. The eagle, raptor pole, and Canada goose brooding surveys were done by others and results are not included in this report; the evaluation of overall mitigation success must necessarily include these results as well as the results presented in this report.
