The Armstrong Laboratory Aviation Personality Survey (ALAPS) was developed to better psychologically assess aircrew. The 15 scales cover personality, psychopathology, and crew interaction styles. This work provides additional psychometric data in support of its use. A sample of over 1000 male and female student pilots provide thorough norming, additional evidence of reliability, and further construct validity.
PREFACE

This project was funded by the Defense Women's Health Research Program, Air Force Medical Operating Agency, and Armstrong Laboratory.

Appreciation for assistance with this project is extended to Royden Marsh, MD, John Patterson, PhD, Major Steven Caberto, SSgt. Pauline M. Etterle, and William M. Weaver.
SUMMARY

The Armstrong Laboratory Aviation Personality Survey (ALAPS): Norming and Cross-validation.

The Armstrong Laboratory Aviation Personality Survey (ALAPS) was developed to better psychologically assess aircrew. The 15 scales cover personality, psychopathology, and crew interaction styles. This work provides additional psychometric data in support of its use. A sample of over 1000 male and female student pilots provide thorough norming, additional evidence of reliability, and further construct validity.
The Armstrong Laboratory Aviation Personality Survey (ALAPS): Norming and Cross-validation.

INTRODUCTION

The psychological assessment of pilots through testing has a long history with many valuable contributions (Hormann & Maschke, 1996; Dolgin & Gibb, 1988; Picano, 1991; Retzlaff & Gibertini, 1987; Retzlaff and Gibertini, 1988; Flynn, Sipes, Grosenbach, and Ellsworth, 1994; Siem, 1992; King, 1994; King and Flynn, 1995; King, Retzlaff, and McGlohn, in press). Traditional psychological tests, however, are of less than optimal value when applied to the assessment of aviator’s personality, psychopathology, and interpersonal interaction.

There are a few specialized tests used for pilot and astronaut selection. They, however, are not published and hence tend to be obscure. Often they have no standardized administration form, manual, or psychometric data. Tests must have established norms, reliabilities, and validities in order to be properly evaluated.

ALAPS DESCRIPTION

The purpose of the Armstrong Laboratory Aviation Personality Survey (ALAPS; Retzlaff, King, McGlohn, and Callister, 1996) is to provide an inventory with appropriate scales, established norms, high reliability, and solid validities for the aviation industry. The ALAPS was developed using the domain theory test construction model (Nunnally, 1978). This model uses most other construction approaches in a systematic and integrative manner. It includes, in appropriate order, clinical content development, internal statistical homogeneity item selection, and, finally, validity estimate establishment. A sample of 200 student pilots served in the developmental sample. The outcome of these procedures (see Appendix A) included 15 scales each with 16 items.

Format The ALAPS is a 240 item test (see Appendix B). The subject is requested to respond in a "true" or "false" manner as each item applies to the subject. The test usually takes between 20 and 30 minutes to complete. The test may be used in paper-and-pencil format or by computer administration.

Scales There are 15 scales divided into personality, psychopathology, and crew interaction categories. The Personality scales include Confidence, Socialness, Aggressiveness, Orderliness, and Negativity. The Psychopathology scales include Affective Lability, Anxiety, Depression, and Alcohol Abuse. Finally, the Crew Interaction scales include Dogmatism, Deference, Team Oriented, Organization, Impulsivity, and Risk Taking.

Personality Scales:

CONFIDENCE: High scorers view themselves as highly capable,
intelligent, and talented. This can include the negative elements of arrogance, manipulation, and condescension. Clinically these traits may suggest narcissism.

SOCIALNESS: High scorers are extremely social and outgoing. They enjoy others and are socially comfortable. They see themselves as friendly and charming. Clinically this may include elements of histrionic personality.

AGGRESSIVENESS: High scorers are assertive to the point of being aggressive. They take strong stands and tolerate little criticism. They are verbally and emotionally combative. This quality probably does not rise to the level of antisocial personality.

ORDERLINESS: High scorers are orderly in a behavioral and environmental way. Their lives are structured and neat. They are methodical and disciplined. This may clinically rise to the level of compulsive personality disorder.

NEGATIVITY: High scorers are angry, negative, and cynical. They are socially punitive and not pleasant to be around. Clinically this may rise to the level of negativistic or passive-aggressive personality.

Psychopathology Scales:

AFFECTIVE LABILITY: High scorers are generally emotional and reactive. They can be situationally anxious, depressed, and frightened. Moods are seen as changing quickly with little provocation. Affect is volatile.

ANXIETY: High scorers are chronically anxious. They worry and brood. The anxiety interferes with their lives and occupational functioning.

DEPRESSION: High scorers are depressed. Problems include dysphoric affect as well as the cognitive and vegetative symptoms of depression. They report being pessimistic, unhappy, and guilty. Extreme elevations may include clinical major depression.

ALCOHOL ABUSE: High scorers like to drink, drink a great deal, and get intoxicated. Functioning is impaired and there may be social and occupational problems.

Crew Interaction Scales:

DOGMATISM: High scorers believe what they believe is always correct and are not open to change. They are authoritarian interpersonally. They are intolerant of other people, ideas, and actions.

DEFERENCE: High scorers are deferent to a fault. They are submissive and quiet. They concentrate on their job and are
uncomfortable questioning the status quo.

TEAM ORIENTED: High scorers enjoy and believe in teamwork. They value the team effort and team rewards. They do not enjoy working alone and may be inefficient when working alone.

ORGANIZATION: High scorers are systematic and organized. They coordinate and plan all elements of a project. They think things through thoroughly.

IMPULSIVITY: High scorers act first and think second. They often act and talk without sufficient forethought. They see themselves as spontaneous. Others may be less generous in their assessment.

RISK TAKING: High scorers enjoy danger and risk. New activities and situations are not frightening. They are adventurous, unafraid, and fun-loving. They are not necessarily impulsive about their activities; their actions may be calculated and include a rational appreciation of the inherent danger.

Purpose: The intent of the current work is to provide additional evidence of reliability and validity for the ALAPS. Further, with a large sample better norming is possible.

METHOD

Subjects: A total of 1131 student pilots volunteered to take part in this study. Of this number, 124 were female and 1007 were male. The average age of the subjects was 22.6 (sd=2.9).

Procedure: All subjects were tested during Enhanced Flight Screening (King and Flynn, 1995; Callister and Retzlaff, 1996). Approximately 40% of the subjects were tested at the United States Air Force Academy and the rest at Brooks Air Force Base during their time at the Hondo, TX, facility. The Hondo facility provides screening for those having received commissioning through Officer Training School, Reserve Officer Training Corps, the Air National Guard, and the Air Force Reserve.

NORMING

Table 1 provides the means, standard deviations, and ranges for all 1131 subjects for each of the 15 ALAPS scales. As can be seen, most means are relatively in the middle of the ranges. The notable exceptions are the clinical scales such as Anxiety and Depression. While these traits are relatively uncommon in the population, there were subjects who endorsed most, if not all, of the items given the range statistics. Additionally, the standard deviations show reasonable distribution of scores and resolution of the sample.

Table 2 includes the descriptive statistics for the male and female subjects individually. T-tests were conducted to determine gender differences. Males were found to have higher
Confidence and Dogmatism scores. Females had higher Affective Lability, Anxiety, and Depression scores. Perhaps surprisingly, scales such as Aggressiveness and Risk Taking showed no gender differences.

Percentile transformations by gender are provided in Tables 3 and 4. Percentile within the normative sample may be found by crossing the scale name row with the raw score column. For example, a male subject with a raw score of 2 on the Confidence scale would be at the 1st percentile of the normative sample. This subject would probably have a problem with confidence. A subject with a raw score of 15 on the Alcohol Abuse scale would be in the top 99th percent of the sample. This subject would be exhibiting a very high level of alcohol use and be of great clinical concern.

RELIABILITY

Internal consistencies for both the developmental and current samples are presented in Table 5. Here Cronbach alphas have been calculated for each scale. In general, it is necessary to have internal consistencies at least in the .70’s and preferably in the .80’s (Nunnally, 1978). There has been little change in the reliabilities across the two samplings. For the current sample of 1131, none are below .70 and 9 of the 15 scales are .80 or above. The median reliability for the construction sample was .82 and for the cross-validation sample the median is .83.

INTERNAL CONSTRUCT VALIDITY

Table 6 provides the first validity analysis. This univariate intercorrelation matrix of the 15 scales indicates the degree of scale co-variance and overlap. It is desirable to have scales with relatively low intercorrelations to ensure scale specificity. Scales with higher correlations should be theoretically similar in content.

Across the matrix it is apparent that there is not undue scale overlap. Scales are relatively specific. Scales that are correlated are of similar content vein. The highest correlation in the matrix is between Orderliness and Organization. Again, this is appropriate in that those two dimensions are similar. Orderly individuals tend also to be organized. The .77 correlation for these two scales, however, is probably higher than is desirable. Other than that correlation, there are no intercorrelations in the .60’s and only 3 in the .50’s.

Table 7 is a principal components analysis of the 15 ALAPS scales. This is done to determine the underlying dimensionality of the scales. The eigenvalues relatively cleanly suggest a four factor solution. The first factor appears to be an affective factor with Negativity, Affective Lability, Anxiety, and Depression loading highly. The second factor encompasses the shared variance in the Confidence, Aggressiveness, and Risk Taking scales. The third factor includes the highly correlated
Orderliness and Organization scales. Finally, the fourth factor is a social factor with Socialness and Team Oriented scales. In general, this is a very interpretable underlying factor structure. This and the univariate correlations suggest the ALAPS scales are internally valid.

EXTERNAL CONSTRUCT VALIDITY

This cross-validation sample was also administered the NEO-PI-R (Costa & McCrae, 1992). Correlations between the ALAPS scales and the five main NEO-PI-R scales are found in Table 8. The first NEO-PI-R scale, Neuroticism, is correlated with the affect oriented ALAPS scales, Negativity, Affective Lability, Anxiety, and Depression. The Extraversion scale is correlated with the ALAPS Socialness scale at a very high level and to a lesser degree the ALAPS Team Oriented scale. The Openness NEO-PI-R scale taps a subject’s openness to new experiences. It has no high correlations with ALAPS scales. It has a modest negative correlation with the ALAPS Dogmatism scale which makes sense. The Agreeableness scale negatively correlates with the ALAPS Aggressiveness, Confidence, and Dogmatism scales. Finally, the Conscientiousness scale correlates highest with the Organization and Orderliness scales and negatively with the Impulsivity scale. In general, these correlations are logical and of appropriate magnitude. These data support the external construct validity of the ALAPS scales.

Tables 9 through 13 provide the correlations between the ALAPS scales and the 30 subscales of the NEO-PI-R. Each of the 5 main NEO-PI-R scales have 6 subscales of similar but more focal content. These correlations provide a more narrow analysis of the construct validity of the ALAPS scales. In Table 9, it should be noted that the highest correlation with the NEO-PI-R Anxiety scale is with the ALAPS Anxiety scale. The highest correlation with Anger is with Negativity. The highest correlation with the NEO-PI-R Depression scale is with the ALAPS Depression scale. The NEO-PI-R Self-Conscious scale has no peer on the ALAPS. The Impulsive scale, again, has the highest correlation with the ALAPS Impulsiveness scale. Vulnerable has no complement in the ALAPS.

Similar convergence can be seen in the other tables whenever scales have similar names. For example, in Table 13 the NEO-PI-R Order scale correlates highest with the ALAPS Order scale. Indeed, the correlation here is .68 which is typical of these convergent validities and very strong. Again, construct validity for most of the ALAPS scales is seen.

As a multivariate approach to the external construct validity, a principal components analysis was done using the five main NEO-PI-R scales and the ALAPS scales. Table 14 shows the five factor solution. Factor One nicely encompasses the neurotic and affective elements of the two tests. Factor Two is an aggressive dimension with negative loadings for the NEO-PI-R Agreeableness scale and positive for the ALAPS Confidence and
Aggressive scales. Factor Three includes the NEO-PI-R Conscientiousness scale as well as the ALAPS Orderliness and Organization scales. Impulsivity on the ALAPS has a negative loading on this factor. The fourth factor has the Extraversion NEO-PI-R scale and high loadings on the ALAPS Socialness and Team Oriented scales. Finally, factor Five is anchored by the NEO-PI-R Openness scale and has negative loadings on the ALAPS Dogmatism and Deference scales. In summary, this is a remarkably clean factor solution and supportive of the ALAPS dimensions.

In summary, the psychometrics of the ALAPS continue to be very strong. The scales are highly internally consistent and, as such, highly reliable. The cross-sample validity estimates against the NEO-PI-R are high and appropriate. These psychometric statistics are highly supportive of the utility of the ALAPS.
