DTIC QUALITY IMPROVED 3
This thesis describes a component-based methodology for developing a new class of systems called spatial decision support systems (SDSS). The methodology is presented within the context of the development of the ARIES (Army Reserve Installation Evaluation System) software application, an SDSS designed to evaluate and compare site desirability for Army Reserve unit locations. The ARIES SDSS consists of a flexible component-based architecture that seamlessly integrates a user interface, GIS, multi-criteria decision model with associated DSS, and data warehouse. To build the SDSS, the ARIES developers introduced a new architectural paradigm, undertaking a collaborative approach with U.S. Army Reserve Command (USARC) decision-makers to rapidly prototype ARIES using component-based technologies. The developers implemented several domain-specific architectures using a formalized proof-of-concept heuristic, Concept-to-Code (C2C), which conceptualizes user requirements in architectural terms, and migrating legacy data sources into a spatial data warehouse. C2C allowed the resultant ARIES application to be conceptualized initially in general terms, and then specialized architecturally around existing off the shelf components, as design requirements were collaboratively prototyped and implemented within the existing USARC information system infrastructure. C2C facilitated the complete development of a complex, map-based system and accompanying data warehouse in the span of a few months with a technical team of three analysts and programmers. Significant system performance gains resulted from instituting a Migration Architecture System (MARS) engine to extract and spatially enable relevant data sources for geographic querying. Additional performance enhancements were also obtained through the use of rapid, component-based development techniques.

ABSTRACT

This thesis describes a component-based methodology for developing a new class of systems called spatial decision support systems (SDSS). The methodology is presented within the context of the development of the ARIES (Army Reserve Installation Evaluation System) software application, an SDSS designed to evaluate and compare site desirability for Army Reserve unit locations. The ARIES SDSS consists of a flexible component-based architecture that seamlessly integrates a user interface, GIS, multi-criteria decision model with associated DSS, and data warehouse.

To build the SDSS, the ARIES developers introduced a new architectural paradigm, undertaking a collaborative approach with U.S. Army Reserve Command (USARC) decision-makers to rapidly prototype ARIES using component-based technologies. The developers implemented several domain-specific architectures using a formalized proof-of-concept heuristic, Concept-to-Code (C2C), which conceptualizes user requirements in architectural terms, and migrating legacy data sources into a spatial data warehouse.

C2C allowed the resultant ARIES application to be conceptualized initially in general terms, and then specialized architecturally around existing off the shelf components, as design requirements were collaboratively prototyped and implemented within the existing USARC information system infrastructure. C2C facilitated the complete development of a complex, map-based system and accompanying data warehouse in the span of a few months with a technical team of three analysts and programmers. Significant system performance gains resulted from instituting a Migration Architecture System (MARS) engine to extract and spatially enable relevant data sources for geographic querying. Additional performance enhancements were also obtained through the use of rapid, component-based development techniques.

ACKNOWLEDGEMENT

First and foremost I want to thank my family for allowing me the time to work on this project.

I would like to thank Professors Dolk and Thomas for giving me the opportunity to work on this project and for allowing me to take this topic in the direction that I wanted it to go.

Thank you to LCDR Dale M. Courtney for his assistance as second reader. His insights and guidance were very important to the final product of this thesis. He offered a objective opinion of someone outside the details of the ARIES project.

The development of the ARIES prototype would not have been possible without the generosity of Professor Barry Frew. He allowed the development team full use of a desktop computer that was essential to the projects success.
I. INTRODUCTION.

“There is nothing more difficult to take in hand, more perilous to conduct, or more uncertain in its success, than to take the lead in the introduction of a new order of things.”

“We are living in an information age where almost everything is seen as technically possible given the commitment and the resources.”

Martyn Jones,

“We can no longer afford stovepiped systems. And it’s not just an affordability issue, it’s a warfighter issue.”

General Ronald Griffith, Vice Chief of Staff of the Army, 1997.

A. THESIS OVERVIEW.

The primary purpose of the research conducted for this thesis is to investigate and document the architectural approaches used in developing the Army Reserve Installation Evaluation System (ARIES) spatial decision support system (SDSS) for the United States Army Reserve Command (USARC). The objective of ARIES is to automate the process of evaluating, potential relocation sites for units of the Army Reserve from the vantage point of military readiness.

Successful implementation of the ARIES SDSS could greatly assist the Army Reserve in its effort to ensure that a consistent, analytical approach to relocating units is adopted. Additionally it would also significantly reduce the time spent by USARC decision-makers manually tracking, calculating, and assessing the multiple criteria relevant to each facility’s site desirability. The use of information technology (IT) in the form of an architecturally-driven prototype application can improve the quality, timeliness, and accuracy of the Army Reserve Unit relocation decision specifically, and of similar spatially oriented decisions in general.
B. THE MOTIVATION FOR ARIES.

The sponsor of this research is the Force Support Package (FSP) Readiness Office, a hierarchical component of USARC based in Atlanta, Georgia. This group is tasked with properly assessing and improving the military readiness of priority Troop Program Units (TPU). In the spring of 1996, several field-grade officers of the FSP approached the Naval Postgraduates School (NPS) building a decision support system to automate and expedite the selection process for relocating Army Reserve units. The manual process currently in use is unnecessarily complex, unwieldy, and limiting for USARC decision-makers, and a technical solution offers increased degrees of freedom in making these crucial readiness decisions.

Under the mantra of “Resources to Readiness”, USARC and NPS formed a collaborative partnership to explore the concept of automated decision-making for site location decisions. The research project was undertaken by an NPS team of two academic principal investigators and three application developers. This team identified location as one of the critical factors affecting unit readiness, and based upon this assumption, implemented a computer based decision model to support the unit relocation. A spatial decision support system was used to leverage the geographic nature of the decision problem.

C. OBJECTIVES, SCOPE, AND METHODOLOGY.

1. Objectives.

The ARIES application was accomplished by integrating a multi-criteria Army Reserve unit-decision model (ARU-DM), over a dozen USARC data sources and geographic information system (GIS) into a SDSS. The SDSS was developed using rapid
prototyping based upon a component-based development heuristic, Concept-to-Code (C2C), and domain-specific architectures. The design heuristic was used as a structured means to assist the end users in conceiving the desired system, to facilitate development of a Data Migration Warehouse (DMW), and to enable the developers in systematically engineering the SDSS application to fit within the existing USARC Headquarters IT infrastructure.

The objective of this research is to describe how the C2C approach facilitated the development of a complex, map-based, multi-criteria decision support system with a small team in a matter of months.

2. Scope.

This thesis addresses only the issues involved in architecturally developing and implementing the ARIES SDSS using component-based technologies. For a more complete examination of the issues involved in framing the Army Reserve Unit Decision as a Multi-Attribute Utility Theory model, refer to LCDR Mark A. Murphy’s master’s thesis “An Automated Spatial Decision Support System for the Relocation of Army Reserve Units” (Murphy, 1997). Additionally, the development of the Data Migration Warehouse was spearheaded by LCDR Robert W. Dill and the issues of data warehousing and data quality are discussed in his master’s thesis “Data Warehousing and Data Quality for a Spatial Decision Support System” (Dill, 1997).

3. Methodology.

The primary function of the ARIES SDSS is computation of the twenty decision parameters identified in the ARU Decision Model from the extracts of designated data sources in accordance with elicited processes and user selections. USARC specified that the ARIES SDSS should access only the existing Information Systems (IS) infrastructure
and historical databases as the primary sources for computing decision model parameters. This avoided the need for additional data collection and data normalization. The impact of this constraint on the ideal model structure, derived from user specified requirements, was carefully evaluated and implemented. Managed data resources were properly identified from those readily available to USARC. The consolidation of multiple sources into an appropriate database schema for this software application presented a significant technical programming challenge.

Due to the limited availability of programming resources and user specified requirements, the SDSS needed to integrate various commercial software tools. An RDBMS and a DSS were combined to manage and manipulate the data. Because of the spatial significance of many of the variables, a GIS was also incorporated for both displaying, selecting, and manipulating the information. The proposed software system contains five major subsystems: the ARU decision model, a single point user interface, data migration management, geographic information system (GIS), and a client-server architecture design.

To rapidly accomplish these tasks required the development team to concurrently innovate and integrate several technical disciplines in ways not previously envisioned. The final result was a SDSS prototype that incorporates the leading-edge aspects of spatial mapping, geographic selection, data warehousing, and decision support technologies.

Component-based application development based upon a systematic and architecturally-driven approach was used in developing the ARIES SDSS client-server architecture. Rapid prototyping techniques were also used to conceptualize the product design in accordance with user requirements and provide functionality for differing levels of detail in capturing the decision knowledge.
The current version of the ARIES SDSS prototype was implemented by the NPS development team using Microsoft's Visual Basic for Applications (VBA) programming language with and third-party software including MapInfo Corporation's integrated mapping components, MapInfos' Basic development language, and the Logical Decision for Windows (LDW) decision support system. The SDSS was based on the client-server computing model and used the Microsoft OLE 2.0 communication protocol as the primary means of component communication.

D. ORGANIZATION OF THESIS.

This thesis contains useful information on building applications using component-based development from a software architectural point of view. It should be particularly valuable to decision-makers, information system architects, computer programmers, and data managers. The balance of this study is structured into several modules and organized as described below:

- **Chapter II** - Opens with a futuristic scenario description about potential uses for next generation (NEXGEN) versions of ARIES. Additionally, a background discussion is provided about the USARC organization, their need for a SDSS and an overview of the intended system.

- **Chapter III** - Discusses the benefits of using component-based development in conjunction with a new software architectural paradigm (Architectonic) through the use of a design heuristic (Concept-to-Code). This chapter closes by describing the ARIES SDSS creation using the design heuristic.

- **Chapter IV** - Discusses the lessons learned from using component-based development and rapid prototyping when developing complex spatial applications using existing infrastructure.

- **Chapter V** - Provides future recommendations for further study and presents the conclusions of this thesis study.
II. BACKGROUND.

"Nothing is Built unless it is Imagined First."
NRaD "Command Center of the Future" Motto.

"Our ability to imagine complex applications will always exceed our ability to
develop them." Grady Booch, Object Solutions, 1996.

"The hardest single part of building a software system is deciding precisely what
to build."

A. FUTURE SCENARIO.

1158 HRS: Colonel Jackson R. McMurdo, Army liaison to the newly formed
BRAC Commission 2000 on active and reserve Army unit basing matters, was looking
forward to devouring his pastrami on rye when the phone rang unceremoniously. He
answered impatiently and immediately recognized the frantic voice of Randolph Braid,
Senator Jeremiad Beauregard's BRAC aide. McMurdo knew the drill without hearing
another word. As the BRAC chairman, the senior Senator from the Southeast was taking
considerable heat from the Senate Armed Services Committee about closing bases V, X,
Y, Z, and corresponding Army unit relocation. An alternative plan consisting of only
closing bases X, Z, and adding bases W and U had been suggested by the Committee,
wherein the displaced Army units would be relocated to base Y. This was an
unanticipated scenario based on previous assumptions and findings, and the Senator
would need this counter-proposal analyzed before reconvening within the hour, or the
whole BRAC list could lose the full support and recommendation of the Armed Services
Committee.

"How does it look if we keep open bases V and Y and close bases U, W, X, and
Z?" Braid asked breathlessly.
“Off the top of my head it appears to be a viable alternative, but I’ll have to run it through the SDSS to be certain.” McMurdo disliked these incessant fire drills from Congress and let his pique slip ever so lightly into his tone.

“Jack, we need you to disregard the condition of the equipment and facility age, and focus instead on civilian employment and impact on the community at large if those bases are closed and their units relocated.”

“Consider it done. Just ensure the Senator’s NetPC Pointcast is set to receive multi-broadcast material and the multimedia presenter is in automatic mode.”

“Understand. Thanks Jack,” said Braid contritely, hanging up his cellular phone.

1206 HRS: Turning in his chair while setting his lunch aside, Colonel McMurdo stoically started his wireless laptop and logged into the Pentagon’s DoD Intranet. Accessing the U.S. Army website, he launched the “ARGIS 2I” applet and began configuring the network user interface (NUI) for the appropriate mapping component and DSS model preferences.

He then entered the Dept of the Army Data Warehouse and chose the applicable DataMarts and databases on military leadership, readiness, competition, and status-of-forces to be integrated with the OMB Economic/Financial databases and U.S. Census Bureau City/State DataWarehouse.

1209 HRS: Selecting the “Build Scenario” function, the ARGIS DataMigrator began extracting and conditioning the desired data to a disposable database on a remote RDBMS server. Simultaneously, the ARGIS DataIntegrator began creating various communication links to the BRAC decision model, spatial mapping components, and the new BRAC DataDepot.

1217 HRS: Colonel McMurdo graphically chose the Army units and bases to be evaluated and executed the scenario analysis. Using remote automation workflow technology, the process co-opted idle network processors to achieve a standard solution
in two minutes. From this baseline the Colonel reduced the weighting on facility age and condition whiling increasing civilian employment valuations. He did not like what he saw.

1221 HRS: Defining a 300 mile radius “what-if” circular analysis polygon around the target site, the Colonel redirected the ARGIS AI-Analyzer to determine which units must be moved to the target site of interest to achieve the desired outcomes. ARGIS reverse engineered the spatial environment and recommended several courses of action and budgetary schedules to achieve the objective over the course of the base closing timeline. This looked much better. McMurdoo recognized the resultant solution as one minimizing the economical impact to a thriving community. He reviewed and selected the analysis summaries that respectively best supported and contradicted the Committee’s argument.

1232 HRS: Using the ARGIS Animator, he converted the analysis to a data visualization movie displaying the best solution with different color-coded alternatives over time as bases closed and units relocated. He graphed the economic impact thematically per site over time and marveled at the efficiency of the system.

1244 HRS: The telephone rang again. It was Braid once more. “Jack, the committee’s reconvening early! What have you got? We have to tell them something.”

“No problem, I have just broadcast the textual analysis to Beauregard’s NetPC on the Senate floor and the ARGIS Solution should be playing on the large-screen display as we speak.” McMurdoo was calm and amused as he noted the contrast of his demeanor with Braid’s anxiety.

“Thanks Jack,” said Randolph. “You saved our bacon on this one.”

1701 HRS: Jack tuned his computer into the Inet-CNN broadcast and allowed himself a small nod of satisfaction to see the lead story was about a remarkable breakthrough in the BRAC closure plan impasse. As newscast switched to the ARGIS
animation film, a voice-over announced in serious tones, "In a dramatic eleventh hour move, a compromise was reached in the Senate today."

As he watched the screen, his mind lamented about his previous assignment to USARC Headquarters so many years ago. Catching himself smiling, Jack spoke aloud, "Who would have thought the progeny of the ARIES project would have been so....

B. USARC AND READINESS.

The previous scenario may seem like a work of science fiction, but given the continued proliferation of information-based technologies, this future may be a lot closer than we think. Until a year ago, if the United States Army Reserve Center (USARC) needed to move a reserve unit, the analysis to manually evaluate several alternatives required a Herculean effort on the part of the Army analysts. The proposed site selection process could take up to 30-40 days to develop just a partial solution. This was due to the complexity of the decision, multiple disparate data sources, quantifying subjective judgments, and analyzing approximately 1300 possible alternatives. Today, with the successful partnership between USARC and the Naval Postgraduate School (NPS), the same analysis can be completed in minutes using a deployed stand-alone Spatial Decision Support System (SDSS) called ARIES, that shares many similar concepts to ARGIS 21, only in a more primitive and prototypical form. The ARIES concept consists of a delivery portion and a data and applications portion. The delivery system includes COTS hardware and software that provides workflow automation by calculating design model parameters. The data and application software satisfied the functional requirements for maintaining the data sources, automating business processes, and interfacing with the decision-makers.

The purpose of this research is to increase readiness using Information Technology (IT) in a manner that will dramatically improve the process used to select
relocation sites for Army Reserve Units. The final outcome is a repeatable and accurate process whose cycle time collapses from 40 days to an average of eight minutes per site selection scenario.

These order-of-magnitude improvements in analysis capability can be directly linked to the decentralized improvement in IT practices from host-based computing (mainframes) to a distributed, network-centric computing environment. Computing environments that previously were relatively simple have exploded into a plethora of networks, clients, servers, and component-oriented systems. Computing complexity has skyrocketed and with it the future potential for greater usage. Technological choices, although daunting, have now begun to take into consideration the issues of scalability, extensibility, and an increasingly uncertain future. Technological solutions are becoming the means to effectively and efficiently increase military readiness.

At the 1994 Software Technology Conference in Salt Lake City, Utah, the Honorable Emmett Paige, Assistant Secretary of Defense for C3I illustrated the strong interdependence that exists between information technology and military readiness in his keynote address:

Software drives Military Readiness. As such, our military state of readiness is changing to support fighting and winning two major regional conflicts at the same time. As the world situation changes, it becomes increasingly the case that we will have to project our military capability with less notice and more precise results. The Secretary of Defense has made it clear that our highest priority must be readiness. We must get our software act together...and provide the support that our war fighters need, wherever they are, no matter how short a notice. And we must proceed with a sense of urgency in making our software become predictable, in the sense of its high quality and high contribution to the defense mission. (Paige, 1994)

This situation presently confronts all military commands, and the work described in this thesis takes a useful step forward in answering the challenge of increased readiness for the U. S. Army Reserve Command.
1. United States Army Reserve Command.

Public Law 101-510, the Defense Authorization Bill of November 5, 1990, provided for the establishment of a U. S. Army Reserve Command under the command of the Chief of Army Reserve (Figure 2-1). "Since the completed transition on September 30, 1992, the USARC has assumed peacetime command and control of all United States Army Reserve forces, except for Special Operations elements and United States Army Reserve forces located outside of the continental United States" (DOD IG, 1993, p. 12).

The Department of Defense's 1993 Inspector General, described the USARC mission objectives as follows:

- "Command, control, support, and ensure wartime readiness of the U.S. Army Reserve Forces.
- Organize, train, and prepare U. S. Army Reserve units for mobilization and commitment to a wartime theater of operations.
- Manage and execute all Operations and Maintenance, Army Reserve (OMAR) and Reserve Personnel, Army (RPA) funds allocated by Headquarters, Department of the Army.
- Support mobilization as directed by FORSCOM." (DOD IG, 1993, p. 14)

In order to comply with these ascribed functions, USARC "...decision-makers must be able to effectively manage the resources supporting readiness and mobilization preparedness" (DOD IG, 1996, p. 22).

The capability to accomplish this goal is directly related to the management and availability of information. The existing...Army Reserve information systems are unable to provide timely and accurate information to decision-makers to...[enable either unit relocation or] mobilization planning...as required to meet contingency plans. (DOD IG, 1996, p. 22)

The Army Reserve Command must often manually compile information requested by commanders and higher headquarters. Additionally updating information is time and manpower intensive and, therefore, is often not done as frequently as needed. (DOD IG, 1996, p. 23)
Figure 2-1. U.S. Army Reserve Management Structure. After (DOD IG, 1993, p. 13)
With the 1994 Department of Defense stipulation to buy Commercial Off-The-Shelf (COTS) technology whenever possible, USARC is currently migrating its information systems and networks from legacy applications and databases to well-supported commercial software suites running Microsoft Windows 95 and NT-based environments.

Because of the huge expense of maintaining and operating legacy information systems, limited resources are available for new application development. Failure to think strategically about software development has lead to the formation of many stove-piped applications and "data silos of information." In order to counteract this downward spiral, the high costs of these systems must be effectively leveraged using commercial technology. Instead of deploying systems that meet USARC's short-term needs, USARC needs to develop applications capable of change and of evolving with changing business processes.

In response to this challenge, USARC established a partnership with the Naval Postgraduate School to develop an Army Reserve Unit Decision Model (ARU-DM) and SDSS prototype to automate the site relocation analysis of existing reserve facilities/units.

2. Readiness Issue.

The sponsor of this research is the Force Support Package (FSP) Readiness Office, a recently formulated component of the U.S. Army Reserve Command. This group is tasked with assessing and improving the readiness of priority Troop Program Units (TPU) across the country.

A TPU is the basic building block of the Army Reserve force, typically consisting of about 150 reservists. The TPU's that are of most concern to the Readiness Office are in the FSP, which are the units designated for rapid deployment. (Murphy, 1997, p. 1)

Military readiness can be classified into two types, operational and structural, which differ in granularity (Betts, 1995). Operational Readiness deals with status of
individual units whereas *Structural Readiness* deals with the overall force structure in the sense of "how soon a force of the size necessary to deal with the enemy can be available" (Betts, 1995). The focus of this research is on the operational readiness of those Army Reserve units scheduled for rapid deployment. In this context, readiness primarily refers to personnel readiness, the ability to maintain enough properly trained and qualified people.

The statistics chosen by USARC decision-makers to function as the primary indicators of unit operational readiness are Fill Level, MOS Qualification Level, and Turnover Rate. The high personnel turnover rates recently suffered by the USAR have significantly reduced readiness. With the average retraining period lasting nine to ten months, between 20 and 30 percent of the required positions are routinely filled by unqualified, non-deployable individuals (Murphy, 1997, p.13). Although Military Occupational Specialty (MOS) qualifications are not always a direct measure of warfighting capabilities, unqualified individuals directly diminish the number of soldiers available to supplement active forces.

Performance in these areas can be related to numerous location-dependent factors, ranging from access to preferred recruiting markets and distances to various training support sites. The most significant location related factor is the recruiting market; for unlike the active services, reserve units must recruit exclusively from the local population. When a unit is struggling to maintain personal readiness, sometimes the best solution is unit relocation. This thesis is based on the "...premise that, holding all other readiness variables constant, it is possible to improve the operational readiness of some Army Reserve units by relocating them to preferred areas as indicated by a variety of location-related attributes" (Murphy, 1997, p.13).
3. Army Reserve Unit Decision Model (ARU-DM).

Before the creation of a manageable model could proceed, it was necessary to clearly define the TPU relocation problem.

Although USARC representatives suggested a variety of ways in which to understand the importance of unit location (e.g., distances, market supportability areas, overlap between units, etc.), it quickly became clear that the primary objective was to relate location to unit readiness. The decision was made to develop a [decision] model that could isolate and evaluate the location sensitive portion of the unit readiness problem. (Murphy, 1997, pp. 19-20)

“Our methodology was to interview the USARC experts to determine:
• A goals hierarchy consisting of intermediate goals and decision parameters,
• Tradeoff functions for each parameter in the goals hierarchy, and
• [Identify the appropriate] weights for each of the parameters.” (Dolk, et. al., 1996).

Based upon the concerns and priorities of the USARC experts, the NPS development team decomposed the overall objective of Site Desirability into twenty measurable decision parameters. These parameters were identified as objective, measurable attributes of a desired site location and loosely grouped together in three categories: People, Places, and Things (Table I).

Table I. Army Reserve Unit Decision Model (ARU-DM).

a. General Assumptions

Although this modeling effort "...does not provide a rigorous, causal model of readiness, it is assumed that the hierarchy of screening factors provides a meaningful assessment of the propensity of a given location to support the achievement of high levels of readiness" (Murphy, 1997, p.31). For the ARU decision model, the expert panel assumed that the basis for evaluation would be a single reserve unit. One alternative to this, relocating a portion or derivative of a unit, may sometimes be more appropriate, but this was not considered in the decision model. Secondly, derived reserve unit metrics had to be calculated directly from data sources available on the USARC local area network which would be implemented in the final application. Lastly, the "area of the proposed site" refers to the region within 50 miles of the zip code centroid center in which the proposed site is located.

This proposed location will have little or no influence on where people chose to live. People will not move just to be closer to the unit or relocate when the unit does. (Murphy, 1997, p. 30)

b. Goals Hierarchy

Using the identified decision parameters, the ARU relocation decision was structured into a goals hierarchy using Multi-Attribute Utility Theory (Figure 2-2). Location data are extracted and conditioned from USARC's corporate data sources and
Figure 2-2. ARU Decision Model Hierarchy of Goals. Each component of the hierarchy is organized by its type (goal, subgoal, or parameter) and identified by the hierarchical level at which it exists. Within each section, components are listed alphabetically and levels are ordered from top to bottom. After (Murphy, 1997)
converted to common units of reference using twenty different utility function curves. There was one utility curve developed for each decision parameter. The outputs of these utility functions are repeatedly combined, based on the hierarchical structure of the ARU-DM and the relative weights elicited from the experts, to produce the overall scores used to rank the alternative sites.

c. **DSS Software Component**

The COTS software package selected by the NPS Development Team for implementing the ARU-DM was *Logical Decisions for Windows* (LDW). It was chosen as the DSS software component "...primarily because it supports explicit specification of tradeoff functions for each parameter as well as five different decision analysis techniques, both quantitative and qualitative" (Dolk, et. al., 1996).

4. **USARC Source Data.**

The SDSS prototype was originally implemented as a stand-alone Windows 95 version but is currently operating in a Windows NT environment on the USARC Headquarters' Local Area Network (LAN). One of the stipulated pretexts of the prototype was that the databases currently present on the USARC LAN are the only data sources eligible for deriving ARU-DM parameters. The primary reason for this is that USARC wanted to be able to deploy the SDSS application without having to shift the burden of administratively supporting it to the USARC IS Staff.

The native data sources are composed of a multitude of large multi-vendor databases (Table II). These databases are mostly flat file structures that were haphazardly instituted to support several independent USARC applications as they were deployed on the LAN. Some of the files are ad hoc derivatives of larger off-site mainframe-based databases, periodically updated from USAR Headquarters in Washington, D.C.
Ownership and maintenance of the local data sources is distributed amongst the primary user base of the stove-piped applications (Appendix A). Additionally, there is no centralized data dictionary or repository maintained for the data sources or the metadata that constructs them. Consequently, there is little consistency between the data source’s design, structure, format, or key index fields. Database field names are different for similar data sets, and most of the files contain incomplete, inaccurate, and missing data. This complete lack of common institutional data standards greatly complicated the development of an integrated data framework for the SDSS prototype (Figure 2-3). To compensate for this unexpected lack of data quality and to provide a stable baseline database for deriving the decision parameters, the development team was compelled to

5. **Information Systems Challenge.**

Because the entire TPU relocation decision incorporates such a large number of parameters, it is nearly impossible for an unaided human decision-maker to fully consider all relevant factors. In the past these decisions were typically based upon a combination of intuition and experience, but this ad hoc process was often difficult to build a consensus for, communicate, and defend.

Frustrated with the inadequacies of the approach to such a complicated problem, the large number of characteristics per facility, the number of analyses required, and over 1300 facilities to evaluate, the Army Reserve believed it could deliver more comprehensive relocation decisions by applying a Geographic Information System (GIS) and decision-support technology to the relocation decision process. In addition the decision support technology had to allow the USARC decision-maker to perform a variety of ad hoc analyses of multiple readiness factors to ensure that the relocation recommendation was truly warranted and was in the best interest of the moving unit. This was the inspiration for a fully automated software application that could select, calculate, and deliver spatially-oriented decision data to the ARU Decision Model. This visionary aspect of the NPS Initiative, “A Geographic Information System Approach to USAR Unit Readiness,” inspired the development of just such an application — the Army Reserve Installation Evaluation System (ARIES).

In order to minimize application development time and maximize previous USARC computing investments, it was important that the automated ARIES system utilize the USARC IS infrastructure, COTS applications, and historical databases as the primary components for computing the decision model factors (Figure 2-5).
Additionally, the NPS development team also wanted to prevent the construction and deployment of yet another requirements-driven stove-piped application (Figure 2-6), instead building one that was architecturally-driven (Figure 2-7). By this I mean an application in which the specific requirements are traceable, the architecture is not resistant to change, and the coding is kept to minimum by leveraging the existing software infrastructure. This is the real challenge of developing the USARC SDSS application.

To accomplish this requires a fundamental shift in the way developers think about and design integrated software applications. Instead of focusing on the problem as "a simple matter of programming," the development team would focus on the problem as a complex systemic concept with interdependent resources and corresponding rule-based processes. To manage this approach effectively requires a new rational design process — the process is partially proof-of-concept exploitable, fully component-oriented, and architecturally refinable.
In the next chapter we will investigate the reasons for focusing our development efforts on architectural design and implementation, develop a component-based heuristic that incorporates architecturally-driven concepts, and specifically discuss the application development and implementation issues that went into designing and building the ARIES SDSS prototype.
III. ARIES APPLICATION DEVELOPMENT.

“He who does not lay his foundations beforehand may by great abilities do so afterwards, although with great trouble to the architect and danger to the building.” Niccolo Machiavelli, The Prince, 1532.

“By 1999, component software will be the dominant method of new application development (0.7 probability)” Roy Schulte, Gartner Group.

A. INTRODUCTION.

There is no single product, book, management style, or “silver bullet” that magically leads the developer or development team through a painless application development process. “But a sensible use of productive complementary tools and techniques, and a shift to a paradigm with proven advantages can over time yield the desired results” (Tkach, 1996, p. xiii). In the absence of any singular solution, the ARIES project used a “proof-of-concept” heuristic, Concept-to-Code (C2C), to guide the development team. C2C provided the structural perspective needed to manage USARC’s requirements and the implementation of the decision model into a cohesive, integrated prototype using various COTS products, a fourth-generation language, and existing infrastructure.

This chapter begins with an overview of component-based development and the new computing paradigm shift it ushers forth. Next is a discussion of the generic requirements of each of the C2C phases, stages, and artifacts, and the corresponding ARIES implementation. The final major section is a summary of the ARIES implementation using the C2C heuristic process.
B. BACKGROUND.

1. Software Development: A Brief History Lesson.

Prior to the 1990’s, software development consisted primarily of programmers and developers using conventional software development models (waterfall, incremental, spiral) to build applications with procedural techniques. The majority of these approaches involved the systematic use of five basic steps: analysis, design, implementation, testing, and maintenance. This was usually sufficient as long as the users’ requirements were clearly defined, system architectures were understood, complexity was low, and product delivery cycle was measured in years.

One problem with the conventional ‘waterfall’ software development process is that in some situations it may not be possible to define the software requirements fully at the beginning of the software development effort. Another problem is that there may be a significant risk that the design approach created to satisfy the requirements may be inadequate. A final problem is that the user only receives the software at the end of the complete and lengthy process; the user may need this capability at an earlier time. (USAF-STSC, 1992, p. 15).

Conventional software practices exploited “...the idea that if developers can get perfect specifications up front, the end result will be a perfect application” (Whitten et. al., 1994). Today this is not the case. As computing power and user capabilities have increased with technological change, the following phenomena transpired:

- The application development process has become more complex today than a decade ago (Tkach, 1996, p. 17).

- “Line-at-a-time programming is...increasingly being replaced by point-and-click visual development environments” (Sarna and Febish, 1996, p. 27).

- “Interactive GUI, distributed...processing, very large integrated...databases [and] heterogeneous environments....” have become the norm. (Tkach, 1996, p. 17).
Additionally, most users have become accustomed to a window-oriented user interface (U/I), and subsequent interface expectations have risen accordingly. The application development process "...has evolved to the point that it's becoming entirely GUI-based and built up from components using techniques of rapid application development" (Sarna and Febish, 1996, p. 27). Complex GUIs are becoming standard requirements that are not easily accomplished with current techniques. The software development methods of the past are insufficient to develop rapidly the scalable, extensible, and flexible applications demanded by organizations today. Speed of delivery and completeness of stated requirements are the mantra driving the "solution du jour."

Currently, organizations want software development to take into account the hundreds of millions of dollars invested in building IT infrastructure, computing capacity, and the resultant morass of accumulated data. The "waterfall" models have failed to provide the "silver bullet" solution to application development in today's "Buy-It versus Build-It" mentality. In turn, they have become the legacy methodologies of the same legacy data, applications, and systems they helped to create. A better solution needs to be found. One answer lies in the increasing popularity of component-oriented computing; with the continued maturation of the software industry, component-based development is now seen "as an important step toward the industrialization of software that can help to transform programming from an arcane craft to a systematic...process" (Taylor, 1991, p. iii).

2. Component-Based Revolution

Component-based development, the ability to design and build from definable objects without the benefits of inheritance or polymorphism, is ready to be the next great advance in software development. Although the concept of constructing applications with reusable code as been available since the object-oriented revolution, it is only just
recently that critical mass has occurred in the computing industry. The pieces are in place for component-based application development to achieve mainstream status amongst today’s IT organizations. (Chappell, 1997, p. 1)

The major reasons for this are:

- The growing use and acceptance of Microsoft’s Component Object Model (COM) as the dominant standard for PC-based component computing.

- Components are moving off the desktop and beginning to play an important role in the creation of client/server applications.

- Broad support for designing and developing components and component-based applications with third-party tools and languages. (Chappell, 1997, p. 3)

As a developmental process, component-based development (CBD) “...will supplant earlier programming archetypes, such as structured programming and object-oriented programming, as the approach most likely to yield significant productivity and reusability benefits. Its emphasis on iteration sounds the death knell for the traditional ‘waterfall’ model of the entire development process. One of the reasons that CBD will gain broad acceptance is that it offers ways to address the complete range of software challenges, from operating system services to client/server development.” (Spitzer, 1997).

Component-based development is not without its own baggage, however. As more and more organizations and vendors shift their focus to take advantage of this new wave in computing, the more susceptible they will become to the unintended consequences of the “revolution.” One of the biggest challenges in the component-oriented “revolution” so far is the utter lack of any kind of established methodology for effectively guiding the conceptualization, analysis, and implementation of a user-centric application, or managing component-based construction from infrastructure components.

Additionally, there is not a widely accepted standards-based component architecture from which to develop applications. Compounding this problem is the fact that almost every component-oriented solution is unique in its configuration and implementation. Traditional software development methods do not apply. The model
currently most applicable is the one an organization develops for its own IS operations and IT environment (Hamilton, 1994, p. 43).

The other reality is that open component architectures — with their interdependent servers, databases, clients, and protocols — have a multitude of potential connection point failures” (Hamilton, 1994, p. 43). Although, we are still better served by past software development practices, it continues to remain horribly expensive to construct custom software for automating a particular organization’s unique business processes (Udell, 1994, p. 47). “...Today’s major problems with software [development] are not technical problems, but management problems” (DOD-USD, 1987). Developers need an efficient means in which to manage and “pre-engineer” modular applications, databases, and information flows prior to deployment in a real world environment. Because the systematic construction of complex software applications from existing components remains an ever elusive goal (Garlan et. al., 1995, p. 17).

From a technical perspective, a combination of component-based development and the latest advancements in software architecture such the ARIES SDSS is required. The prerequisites for this would need to include:

- A widely accepted component-oriented infrastructure.

- Standard Domain-Specific Software Architectures (DSSA) to guide development and enable rapid assembly.

- Commercial and technical environments that fully support CBD integration.

This alone may be the most important paradigm shift in software development in decades. The dawn of the “industrial revolution of software,” whereby software products are manufactured in accordance with a specified structure and process, is upon us.
3. Architectonic Paradigm: The Shift to Structure

"Today the term [paradigm] is widely used to define a broad model, a framework, a way of thinking, or a scheme for understanding reality" (Tapscott, 1993, p. xiii). The Architectonic Paradigm — of or pertaining to principles of architecture — mandates a shift in conventional thinking about how developers build applications. It requires an architectural approach that spans both the business and technical arenas, and that adopts the perspective of software construction not as a craft but as a discipline (Davis, 1995).

This new paradigm consists appropriately of the following aspects:

- Simplicity - easy to comprehend and communicate.
- Task-centric - must map naturally to the customers’ world.
- Changeable - enable rapid, flexible, and scaleable paths.
- Manageable - support heterogeneous platforms, applications and architectures.
- Leverageable - migrate legacy systems and support COTS integration.

In short, the Architectonic Paradigm is one in which the overall focus shifts from requirements-driven to architectural-driven development. It “has all the benefits of requirements-driven style, as well as the favorable characteristic of encouraging the creation of resilient frameworks that can withstand shifting requirements and technological calamity” (Booch, 1996, p. 21). But the days of designing an information system in a vacuum are over. The problems of today are up to 50 times larger in complexity than the problems of yesteryear, and the difficulty of developing “good enough” solutions is growing at an exponential rate. The developer is always trying to fit a new piece into a puzzle that has already been framed and to deal with quirky methods of interfacing with the database(s). A developer can no longer afford to build software applications from scratch without duly considering the existing infrastructure and several components — which are themselves architectures (information, application, and
technical) — contained within the structure. The Infrastructure investment holds a central position in any planned and future application development (Figure 3-1).

![Diagram of System Functions]

Figure 3-1. An Architecture-Driven System. After (Booch, 1996, p. 52).

4. Infrastructure: The Invisible Hand of Structure

The previous chapter briefly introduced the notion of architecture-driven programming and illustrated how it relates to infrastructure. The central idea is to encourage the minimal programming of new applications by using software architectures and COTS products already present within the desired operating environment. An example in a Windows-based environment would be to develop an application’s UI using Windows’s API routines rather than creating new objects and classes in the C++ language. Additionally, the use of validated infrastructure components require that new applications only need to be tested at the points of interaction between existing components and thoroughly tested for any custom designed components. This allows the
developer to safely assemble and application as opposed to building it. The guiding principle is “Buy the Basics, Custom Build only what provides Value” (Knowles, 1997).

Many mature organizations, already dependent on information systems, are struggling to implement this “Best-in-Breed” approach while still maintaining their existing lines of business applications. To accomplish this, organizations must effectively forge a vision for an enterprise architectural foundation with a (capital “A”) and develop domain-specific frameworks that support the integration of single application architectures (with a lower-case “a”). Perhaps, the best approach is to fundamentally leverage the existing infrastructure in a manner that permits organizations and developers to manage heterogeneous components, business rules, and legacy data from an architectural perspective.

The ARIES development team devised the Baseline Infrastructure Archetype (BIA) Model to accomplish this objective, and to better understand and analyze the infrastructure. Although the BIA Model is generic, it forms the centerpiece of the Architectonic Paradigm, and offers guidance for evaluating the features of available components and tools used to solve problems relevant to the unique circumstances of individual applications. Essentially all of the pertinent technology fits into the multi-layer triangular model (Figure 3-2) that incorporates all three infrastructure subarchitectures: information, application, technical. These subarchitectures provide a triad of interaction for all systems within the Architectonic Paradigm:

- **Information Architecture** - describes the content, behavior, and interaction of all the business and information requests from applications and technical components. The information architecture provides the database objects and services for application development and provides a information framework for other requesting resources.

- **Application Architecture** - defines the fundamental services and business rules within the applications domain. This architecture transparently and seamless supports the logic and data processing of the user interface service requests. The components of the information architecture are modeled,
designed, and implemented in terms of the business rules and processes developed in the application architecture.

- **Technical Architecture** - specifies the actual technologies (components) and the software tools that supply the requested services to and from the application and information architectures. It is used to implement the applications. (Aronica and Rimel, 1996)

![Figure 3-2. Baseline Infrastructure Archetype (BIA) Model.](image)

The logical layers of the BIA Model that function from the epicenter (interface layer) outward are:

- **Interface Layer** - Provides client-side services to the resources and user. For a particular user the layer enables access and interaction with application resources.

- **Communications Layer** - Functions as middleware to connect and manage the interface clients with various requested resources.
• **Resources Layer** - Consists of the DBMS, databases, and data; the applications, parts of applications and components; technologies and tools that implement the applications. (Hurwitz, 1997)

Resource interactions that do not require client involvement occur at the angular margins, and the byproducts of interaction are conceptually maintained within the circular segments of the “sphere of influence”. More simply, the sphere represents the scalable world in which the information system functions. Whether it is a standalone desktop computer or a mainframe system, the baseline structure is physically different but logically similar. The ecological environment in which the spherical microworlds operate provide the common platform services:

• Base Operating System (e.g., Windows NT).

• Networking Communications (e.g., NetBUI, TCP/IP, etc.).

The layers in this model are not the same as those found in a typical three-tier client/server model. There is no single service with a single piece of middleware, no single graphical user interface, and no single type of data all tightly connected. You should think of each layer as a category -- an organizing principle. (Hurwitz, 1997).

This layer approach allows developers to plan the function of various pieces of the architecture and determine what to work on first. A specific example of this model will be provided later in the next section.

The next logical question is “How can the benefits of architecture be effectively extended to component-based computing?” The ARIES development team’s response was to devise and institute a methodological heuristic, *Concept-to-Code*, that embraced the Architectonic Paradigm and provided a structural perspective and the means to formulate a cohesively integrated application. This will be the focus of our discussion in the next section.
C. CONCEPT-TO-CODE HEURISTIC

1. Overview

The main disadvantage of major information system development, aside from architectural and infrastructural issues, is that it takes too long to implement full production products from untested concepts. It is very difficult to get beyond theoretical constructs to practical implementations.

What is needed is a new kind of application development, one supported by a set of design ideas that can accommodate pre-existing applications, software infrastructure, and COTS products, and one employing a systematic approach independent of tool, style, or technique that acts to guide and direct the collaborative efforts of the users and developers, and that incorporates Grady Booch’s five elements of a successful project application:

- Focus ruthlessly on the development of a system that provides a well-understood collection of essential minimal characteristics.

- The existence of a culture that is centered on results, encourages communication, and is not afraid to fail.

- The effective use of object-oriented analysis and design.

- The existence of a strong architectural vision and principles.

- The application of a well-managed incremental and iterative development life cycle. (Booch, 1996, p. 25)

Concept-to-Code (C2C) is just that: a way of getting from a concept envisioned by an organization to the specific computer code needed to achieve it. C2C’s primary cognitive focus is to prevent the production of ill-defined software early in the conceptualization process. The heuristic achieves this by exploring and implementing practical solutions in a manner that is independent of a particular computing language,
DBMS, and operating environment. Simply stated, by using rapid application prototyping techniques and the participatory involvement of the intended users, an organization can get exactly what it needs in less time than by conventional methods.

"In business system development, satisfying the needs of the users is particularly challenging because even the user cannot know what he wants and needs until he sees the system in action" (Scharer, 1986, p. 59). Because written specifications are not a good way to communicate with the user, rapid application prototyping was selected by the ARIES development team as a practical approach for developing the U/I and the application. Prototyping in this case becomes a method of system construction as well as a technique for system definition (Scharer, 1986, p. 60). Additionally, it is critical to remember the following when using rapid application development (RAD):

- RAD only works when you understand the business problem.
- RAD should not be tool-driven or tool-dependent.
- RAD is only effective when it's part of a sound application development process. (Linthicum, 1997)

Achieving this RAD effort requires close communication and collaboration between intended users and a small, highly skilled development team (e.g., three to eight people).

The task is to develop a technical artifact for a client or user with more or less clear and stable requirements. To cope effectively with the uncertainty of this task, an experimental approach is taken in which various models, prototypes, and versions are tried to reach a satisfactory solution. (Dahlbom, 1997, p. 84)

By using a methodology or process that integrates the combination of controlled development and rapid prototyping, a developer can ensure minimal risk and maximum benefit in design.

In order to effectively organize the RAD process, C2C was visually conceived as a three-layered closed-loop pyramid structure flowing progressively from top to bottom and iteratively throughout the structure (Figure 3-3). Each layer represents a distinct
“phase change” of the collaborative process, or the completion of an iterative milestone of the developing application. Each phase is further sectionalized into two smaller parts called “stages.” As indicated, each stage flows into each other and acts to facilitate the focus of the user and developer. The resultant IN/OUT processes of each stage are byproducts of this interaction.

![Concept-to-Code (C2C) Heuristic Diagram](image)

**Figure 3-3. Concept-to-Code (C2C) Heuristic Diagram.**

The *Conceptualization Phase* is focused on identifying and clarifying the concept or problem to the extent that the prospective users are able to articulate and the developers are able to assimilate. The artifacts of the conceptualization phase are utilized by the *Visualization Phase* to more thoroughly analyze the problem domain, define and design stable component architectures, and address the riskier elements of the project. This phase will more than likely require several iterative feedback loops to properly create the U/I prototype and application architecture in accordance with the user’s
requirements. The *Implementation Phase* uses the approved byproducts of the Visualization Phase employing appropriate application development principles and fourth generation language coding skills of the developers.

Prior to the transition from each phase/stage, a formal review and informal walkthrough should be conducted to ensure the resultant artifacts are satisfactory and design decisions sound. Usually peer-to-peer walkthroughs prevent a perpetuation of inconsistency and incompatibility between user requirements and developer objectives. "Formal reviews are intended for acquisition management users and interested parties to conclude a software development phase by approving the products and other results of that phase" (USAF-STSC, 1992, p. 55).

A completed cycle of the C2C pyramid and acceptance of the application by the user represents a final incremental version that is ready to be deployed in the desired operating environment. "The process is incremental in the sense that each pass through the...[C2C] cycle leads a project to gradually refine its strategic and tactical decisions, ultimately converging upon a solution that meets the end user's real (and usually unstated) requirements, and yet is simple, reliable, and adaptable" (Booch, 1996, p. 29). Later in this chapter, I will specifically address each phase and stage in turn, but for now it is easier to view each phase and stage as a transition point.

The apex of the pyramid is the highest point of general abstraction and becomes more specialized as the developer gravitates to the foundation. Only as the user-developer collaborative ensemble descends the structure do specific commitments to particular languages, standards, and operating environments emerge, all the while providing a mechanism for feedback that enables architectural refinement and iterative development of the concept. The bisection of the upper half (user-driven) and lower half (developer-driven) of the pyramid, indicates the primary focus of the collaborative effort.
The shaded boxed regions in the first two phases illustrate where rapid prototyping occurs dependent on user requirements:

The *Analysis Prototype* is an aid for exploring the problem domain. It is meant to capture users’ input and show proof-of-concept. The analysis prototype is not meant to be used as a basis for development and it should be discarded when it has served its purpose. The final product should use the concepts exposed by the prototype, not its code.

The *Domain Prototype* is an aid for the incremental implementation of the solution. It can be used as a tool for staged delivery of subsystems to users and other developers. It demonstrates the feasibility and viability of the implementation and will eventually evolve into a deliverable product. (Tkach, 1996, pp. 52-53)

Therefore the amount of prototyping is directly proportional to the degree the user is able to effectively articulate what s/he wants, needs, and desires (Figure 3-4). This dependency upon the judgmental influence of the user diminishes from phase to phase (Figure 3-5). Because of this dependency the prototyping for the ARIES SDSS will be discussed separately at the end of each phase narrative — each prototype situation is uniquely different from the previous, and at a minimum, the U/I-centric nature of today’s applications, increasingly demands prototyping to achieve the best fit, form and functionality in a very short time.

This coordinated prototyping capability is what makes C2C far different from typical application development. It lends itself easily to rapid application development yet is iterative at each phase. “Without a [process] for managing change, all but the smallest, simplest projects are at risk of wandering out of control and adding time to the development schedule” (Forte, 1997, p. 121). The heuristic on the whole is not a cookie-cutter technique, but takes a “systems view” of the concept to be tested and develops the application in steps from concept to system to subsystem.
Figure 3-4. Level of Prototyping Required Graph.

Figure 3-5. User Influence on Application Development.

With this in mind, a more complete definition of C2C is the following:

*C2C is a formalized iterative construct, a heuristic, for developing “proof-of-concept” applications in a top-down, component-oriented architecture in which users’ objectives, business rules, and organizational data are defined and related to one another at the conceptual, technical, and implementation levels.*
The tenet principles upon which this heuristic was based are as follows:

- Manage the complexity of small to medium sized applications (<100,000 LOC) through the use of component-based techniques while still embracing legacy systems.

- Focus development and modeling efforts on components whose function is determined heavily by the user interface and interactions with relational databases.

- Where applicable, adapt to changing requirements by maintaining a strict adherence to open IT standards-based architectures to ensure interoperability, portability, scalability, and data exchange (Libicki, 1994, p.3).

- Ensure application efforts are user-driven, not technology-driven, by leveraging the user and developers intellectual capital through rapid application prototyping.

- Conduct integrated and continuous testing with the C2C process while maintaining a “high level of stability throughout the project by constantly evaluating the architecture, interfaces, and...by preventing the accumulation of latent defects” (Forte, 1997, p. 122).

Now that the basics and underlying principles of C2C have been explained, we can delve into the specific regions of the heuristic and how they help to direct the development of the ARIES application.

2. Conceptualization Phase

Concept-based exploration begins with a broad concept — a “term...meant to suggest a framework that is found useful in organizing ideas and suggesting actions” — and proceeds into a characterization plan to determine and understand the processes of the organization, and identify the top level requirements and feasibility of the concept (Scott-Morton, 1984). It is essential to understand the business-centric aspects of the organization prior to developing the concept. The main goal in the first step of this phase is to identify the concept to be proven, and characterize it in terms with which the user is familiar in preparation for later software development.
The second step in the conceptualization process is identifying the specific capabilities required to execute the concept by focusing on defining as much as possible the elements that best characterize the organization’s stated concept. The goal is to develop a characterization of what the application will accomplish without getting into the details of how the system actually functions. The term characterization is used because process analysis and data gathering are not exhaustive. It is not necessary to document every detail. Only enough detail is required to allow informed decisions to be made in the creation of the component architectures and U/I prototype. Without the insight that a baseline characterization provides, there is a risk of devising a system architecture that is difficult to improve. If the customer already possesses much of the baseline data, more time can be spent on characterizing the environment. Iterative development will subsequently refine the characterization to a specific system.

Much of this information is gathered through a process of interviews with all the individuals (Management, IT staff, and end users) with a vested interest in the application; as well as a thorough audit of the existing environment. It is important that the intended users of the system be fully involved and participative in the conceptual design process. Conceptual errors made in the design are laboriously difficult to correct once coding has begun. Developers prefer to carefully analyze and evaluate the conceptual design before proceeding to the Visualization Phase. If the user has difficulty articulating or characterizing the concept, it is the responsibility of the development team to utilize prototyping as a means to elicit the desired information. The Analysis Prototype can help to “minimize development risks due to incomplete requirements, and to assess whether a user interface can be developed that will allow the designated system to operate effectively” (Dolan, 1994).

Some of the basic concept characterization elements to consider are (not inclusive):
- Top-Level Requirements.
- Scope.
- Timeline for Product Delivery.
- Performance Criteria.
- Technology Base and Infrastructure.
- Business Rules, Processes and Logic.

The user is not asked to freeze the functional specifications during this because specifications can be revised or changed even after the analysis prototype refinement is in progress. Accordingly, this will require a different mind-set than previously conducted by software development teams in the past.

a. **ARIES Concept Stage**

The concept USARC was interested in investigating was whether or not the manual process of relocating Army Reserve units could be automated using existing data sources and computing infrastructure. Specifically, could a Geographic Information System (GIS) be integrated with an ARU-Decision Model to provide users with the ability to graphically select and compare reserve units through a common user interface. The resultant solution, a Spatial Decision Support System (SDSS), would be a new capability that allows the decision-maker to “pull” only the spatially pertinent data about desired facilities and “push” the results into the DSS model.

b. **ARIES Characterization Stage**

The desired ARIES system could best be characterized as a software application that spatially selects, derives, calculates, and imports the user-identified decision parameters into the ARU-DM using USARC data sources.
(1) Top Level Requirements

- SDSS application must be a standalone “proof-of-concept” prototype that will execute on a USARC-furnished laptop computer running the Microsoft Windows 95 operating system.

- Allow the decision-maker to manage the selection of the legacy data sources on the USARC LAN.

- Implement a single, consistent user interface that allows the decision-maker to graphically or manually select the facilities to be compared.

- Automate the calculation of ARU-DM parameters, using USARC business rules, pre-determined data processes, and a GIS.

- Enable the batch printing of pre-determined reports from a default preference set.

- Allow the decision-maker to change parameter weightings and conduct “what-if” analysis on the completed scenario.

- Use as many USARC infrastructure components as possible without adding additional administrative burden to the IT staff.

(2) ARIES Scope

- Data Sources - U.S. Army Reserve Databases (National); Approximately one gigabyte. The functionality of the SDSS had to be proven with USARCs’ existing systems, using data the decision-makers were familiar with.

- Inputs - Unit Identification Code (UIC) of the moving unit and up to four Facility Identification (FacID) unit alternatives.

- Complexity - Support no more than 10 USARC users at a time in the LAN environment.

- Constraints - For calculating applicable decision parameters, spatially select the closest AMSA, equipment and recruiting sites; Conduct all spatial selections within a 50 mile radius of the proposed site; Use USARC’s command plan as a master list to validate UIC’s and G17 files as the master list to validate FacID’s; Indicate inaccurate or missing data for decision parameters with code (-999).

(3) Timeline

- Develop standalone prototype in approximately six months.
(4) ARIES Performance Criteria

- Conduct each evaluation scenario (up to four alternatives) within two hours maximum; Verify each user input using master validation lists; Batch automate as much as possible in order to minimize user interaction and training.

(5) USARC Technology Base and Infrastructure

- **Hardware (standalone)** - Dell Latitude laptop computers with 90 MHz Pentium processors.

- **Hardware (network)** - Numerous multi-vendor desktop computers with Pentium Processors.

- **Operating Systems** - USARC LAN running Microsoft Windows for Workgroups 3.1 with a plan to upgrade to Microsoft Windows NT 4.0 in Fiscal Year 1997. USARC laptops utilize Windows 95.

- **COTS** - MapInfo Professional and MapBasic 4.0 mapping software package. Microsoft Office 95 Suite.

(6) ARIES Business Rules and Processes -- Appendix B

c. **ARIES Analysis Prototype**

Because users cannot always articulate what their business requirements are or their preferences for the user interface, two forms of analysis prototyping were used to better conceptualize the ARIES system.

(1) Contextual. Because direct interaction between USARC and NPS was restricted to a maximum of two days per month a contextual style (storyboarding) of prototyping was used to elicit from the users the desired functionality of the common user interface in terms of visual appearance, menu choices, program controls and toolbar capability. The idea was to distill the “signal from the noise” by starting from the user’s perspective and rapidly discussing, diagramming, and receiving feedback about various interface ideas and alternatives. As each iterative cycle was completed, the
interface became more refined, until all sides agreed upon a interim design. The final computer-based design was completed later as a byproduct of the component architecture prototype in the Visualization Phase.

Because the application was to execute in a Microsoft Windows-based environment, it was important to the users that the user interface mimic and leverage Windows-based functions as much as possible. The main objective was an application that required a minimum amount of training for experienced Windows users and fulfilled all of the stated requirements. To achieve this, the collaborative team agreed that all program views and controls would be subordinate to, and represent only one item at a time within the confines of a master window view. This was needed to maximize user comprehension and minimize confusion. The particular views and controls are as follows:

- Provide a Map View that enables the user to graphically select desired units and monitor the progress of facility comparisons that are spatially selected and calculated.

- Provide a Selection Panel that enables the user to manually input Moving UIC/FacIDs and monitor the status of facility comparison calculations.

- Implement button controls for accepting, starting, resetting and exiting the application.

- Implement a menubar and toolbar that allows the user to manipulate the COTS products in accordance with user requirements.

- Provide feedback to user in the form of a statusbar and a selected facility information view.

(2) RAD-based. A second analysis prototype used a combination of 4GLs, Delphi 2.0, Visual Basic and MapBasic, to develop a rapid application to audit and validate the USARC business rules and data logic for deriving the ARU-DM parameters. This was accomplished by creating relational database links to a subset of the data sources — Army Reserve Units in Pennsylvania — in their existing
format, computing the decision parameters in accordance with the business rules, and outputting the results to a common data file format (e.g., Tab delimited). Additionally, a custom component was created and developed using the MapBasic spatial application development language; a programming language associated with interacting and automating the MapInfo application. Essentially, the MapBasic component functioned as a workflow script that spatially selected the data necessary to calculate several decision parameters within a 50 mile radius. This proved to the collaborative team that the most critical aspect of the prototyping process, using USARC LAN files without modification and coordinating various heterogeneous COTS products, could be controlled by a common user interface. By prototyping ARIES in this way, we were able to obtain clear guidance on how to meet and comply with USARC’s unique military requirements and business rules.

d. ARIES Conceptualization Artifacts

Before proceeding to the next phase, a formal walkthrough review was conducted with all involved to ensure all user requirements had been gathered and the concept properly characterized. It was important to avoid “gold plating” the requirements (e.g., providing more functionality and features than the user needs) by realistically examining the application’s proposed concept and the organizations existing IS/IT infrastructure. The resultant ARIES artifacts of this phase were determined to be the following and are detailed in Appendix C:

- Conceptual Overview Diagram
- USARC Business Rules Specifications (Appendix B).
- User Interface Interim Layout.
- User Interface Final Layout
3. Visualization Phase

Once the business issues are characterized and the application requirements have been defined, the next step is to turn these abstract requirements into an actual tangible architecture. The Visualization Phase does this by providing the means to synthesize the user requirements into functional architectures and component interactions. Unlike current software development practices, C2C does not attempt to clarify the difference between requirements and design. The goal is to facilitate the construction of the needed application using the most appropriate architectures.

The C2C architecture design involves multiple levels of abstraction. At one extreme is the reference or domain-specific software architecture (DSSA); the other is the application architecture itself. The DSSA represents the most general and abstracted form whereas the application architecture represents a specific design solution. In this phase, we categorize the two architectures as macro and micro. The macro-architecture illustrates the “what” and the micro-architecture illustrates the “how” of the application being designed. While the micro-architecture represents a specific technical solution and will change as the application is revised, the functional macro-architecture will remain the stable domain structure. Based on the requirements identified in the previous phase, the macro-architecture is partitioned into modules and the function(s) of each module are defined. The micro-architecture then entails the identification and selection of component software to fulfill these functions. More simply, the micro-architecture key concerns are functionality and performance; whereas the macro level concerns focus upon the management of complexity.

One of the problems of identifying components is that future users of the application often view all of their processes as unique, and therefore desire custom-design components to handle this uniqueness. This is where a proper balance of “Buy - versus-
Build" strategy is needed by application developers; because some of the components may be available in the form of COTS products, and some components may have to be custom developed for the specific function they are required to implement. A good rule of thumb is "Build Business Value, Buy the Basics" (Knowles, 1997). Secondly, a component should be linked to an accepted standard and it must earn its way into the application architecture. The use of architectural styles such as these have several significant benefits:

- Promotes design reuse within the problem domain.
- Often leads to significant code reuse and shared implementations.
- Enables better comprehension of the system’s organization if conventional structures are used.
- Use of standardized styles supports interoperability.
- Permits specialized analysis by constraining the design space. (Monroe, 1997, p. 45).

We envision multiple passes through the Visualization Phase with the macro-architecture being solidified first, the U/I in subsequent passes, and finally the component architecture (micro). Refinement occurs at each iteration with the end user closely engaged in the resultant architecture.

a. ARIES Macro-Architecture Stage

Because SDSS was an innovative concept, there was no pre-existing reference architecture/DSSA upon which to base our design. With this in mind, the collaborative team utilized the artifacts from the previous phase and the BIA model to design a macro-architecture (Figure 3-6):

- Point of Access (POA) Module - the prototyped U/I
- Application Module - includes the ARIES Business rules and processes to capture the ARU-DM decision parameters and transfer them to the DSS.
- **Technical Module(s)** - includes the capabilities to display maps, spatially select data and provide decision support.

- **Information Module** - includes the requisite data and business rules to support the mapping, decision parameter calculation, and decision support functions in the form of a Data Container.

Figure 3-6. ARIES Baseline Infrastructure Archetype (BIA) Model.

Because the movement of data between USARC legacy data sources and SDSS modules has the largest data flows, the development team implemented a container approach to manage all data flows within the context of the macro-architecture (Figure 3-7). The Data Container represents an abstracted data repository that contains all the metadata, source data and COTS support data necessary to the relocation decision, and provides a means for ARIES to be portable for mobile users and to operate independently.
from the USARC LAN for networked users. Source data is migrated to a separate
database structure (data migration warehouse — DataDepot) for the following reasons:

- Provide an accurate, centralized, and high quality — data repository for
calculating decision parameters.
- Principle of minimality - only use whatever data is required to support reserve
  unit site selection.
- Accelerate data exchange between modules by using the native DBMS format
  of the USARC infrastructure.

![Diagram of ARIES Macro-Architecture](image)

**Figure 3-7. ARIES Macro-Architecture Diagram**

*b. ARIES Micro-Architecture Stage*

After considering a number of candidates and conducting an infrastructure
review; the development team identified the primary technologies that fit the
organizational objectives, with which to populate the macro-architecture (Table III). The
information within the Data Container component represents the migrated USARC
source data necessary to support the relocation decision analysis (DataDepot); the
MapInfo data files necessary to support the display of maps and geocoded information;
and the ARU-DM master templates to support the importation of computed decision parameters.

Table III. Macro and Micro Architecture Comparison Chart.

Interoperability between components can be achieved by a variety of means, but it must be delineated in the architectural framework and applied consistently throughout the application. In the case of ARIES, many various communication protocols had to be used to ensure proper component iteration. For example, because the LDW application was originally designed for a 16-bit Windows environment, it was incapable of being controlled via established distributed computing standards (e.g., OLE). Therefore, the development team used intrinsic Windows Application Programming Interface (API) routines to manipulate the LDW window displays and the Visual Basic SendKeys Function to process macro-scripts. In short, the ARIES U/I controls LDW by simulating a user’s input.
c. **ARIES Domain Prototype**

Although each of the technologies brought strengths that USARC wanted to take advantage of, integration of the components into a coherent process that could be controlled from a single point soon became a formidable challenge. The developers were faced with the difficulty of minimizing the coupling and data transfer between the major components in order to maximize application performance. The first step — was for the development team to fully understand all of the components — including their design intentions, capabilities, strengths, weaknesses and external communication protocols. The second step — was to partition the U/I views of the analysis prototype into smaller segments and put the riskiest parts at the top of the prototype list, rather than letting them slip to the end. This “Piece-of-the-Pie” or subset approach, allowed the developers to bind each U/I view in turn to the applicable component (Table IV).

By using RAD prototyping, the development team was able to build the interface quickly and easily using a visual development methodology (VDM), and then using component-based development, to link the U/I to existing data sources, infrastructure and components to ensure connectivity. Later in the Implementation Phase the team would place the appropriate code for business rules and data manipulation behind the approved user interface. In this manner, the abstract interface encapsulated, or hid, the actual system implementation from the end-users. The decision-maker can only view and access the system by way of this single point interface.

d. **ARIES Visualization Artifacts**

Before proceeding to the implementation phase, another formal walkthrough review was conducted with all involved to ensure that the proposed procedural flows, component architectures, and U/I prototype were practical, close to what the user expected, and adhered to specified standards. Figure 3-8 illustrates the final approved component framework solution.

![ARIES SDSS APPLICATION](image)

Figure 3-8. ARIES SDSS Component Framework Solution.
4. Implementation Phase

At this phase in the C2C process, the component architectures and user interface prototyped in the Visualization Phase are translated into source code in 3GL or 4GL syntax. If an RDBMS is involved, the database schema will generated and integrated with the final application. The purpose of the coding is to translate the detailed architecture design into computer language suitable for the designated operating environment.

Prior to this stage the development team “must first agree on the processes and methodologies it intends to follow, and it must decide which of those processes are going to be followed religiously -- and which ones will be honored in spirit, but perhaps not to the letter of the law” (Yourdon, 1997). Once this has been decided, the tools and technology can be chosen — or rejected — accordingly.

a. ARIES Development Methods, Techniques, and Strategies Stage

Once the application has been designed in the form of interacting components, it becomes very easy to add new ones and scale up the functionality of the system or adapt the system to meet a design constraint. This was the case in ARIES for transferring the computed decision parameters to the decision support system. Because the LDW DSS is a 16-bit Windows application, it was incapable of reading Microsoft Access database files without a custom modification by LDW’s development team. The solution was to convert the Access data table to a format that LDW could import reliably. Component testing of the LDW DSS indicated that a Tab-Delimited format was the most suitable and that by using the Microsoft Excel spreadsheet component available in USARC’s infrastructure software suite, the information could be converted and imported quite easily using OLE communication protocols.
Another advantage of the approved component framework, was that once all the required components and interfaces had been specified, many of the coding activities could be performed in parallel as long as the input data necessary for the component was available.

Once the allocations of system requirements to...software components has been made, parallel...software definition, design, and implementation activities are initiated. During these parallel efforts, the...development team must continuously cooperate and communicate to ensure that their implementations are compatible. This continued interaction is critical to the successful integration of the...software components. (USAF-STSC, 1992, p. 20).

b. **ARIES Coding Stage**

The ARIES U/I and application was coded using the Visual Basic for Applications (VBA) language and standard structured programming techniques. Only one form was created during the Domain Prototyping phase which contains all the VBA objects and the integrated MapInfo object of the ARIES U/I. The rest of the partially-compiled application is comprised of several VBA-coded files and one MapBasic program (Appendix D):

- **SUBMAIN.BAS** - Initializes the ARIES U/I; Loads and connects COTS components to U/I; Displays the U/I.

- **UserInterface.FRM** - Contains all procedures, business rules, and logic for controlling the ARIES U/I.

- **PublicDeclarations.BAS** - A library module that initializes all public variables and constants; Contains the variables that represent the SQL business rules for calculating the ARU-DM decision parameters.

- **Library.BAS** - A library module that contains all the procedures called by other procedures more than one time.

- **OLE Library.BAS** - A library module that contains all the procedures supporting OLE communications between COTS components.

- **OLE Callback.CLS** - An object class description necessary for communicating with the integrated MapInfo component.
- MapBasic.BAS - A library module that initializes all public variables and constants for communicating with the integrated mapping component.

- ARIESArch - A MapBasic program that spatially selects the desired data within 50 miles of the specified location and locates the closest Army Reserve support facilities.

Code evaluation occurs during and upon completion of coding. It ensures that coding techniques are acceptable and that standards have been followed during the coding process. The evaluation was conducted by the development team and NPS advisors, using peer-review and informal walk-throughs in order to verify the code against the design, and to ensure compliance.

c. ARIES SDSS Application

The gain in performance of this spatially enabled DSS over its manual counterpart is formidable. A process that previously required weeks, can now be completed in minutes. The SDSS DSSA is very flexible and offers numerous ways of eliciting preferences and displaying results. The structure is adaptable enough that it can be easily expanded to include additional decision parameters, criteria, and improved decision models.

Given the large number of components that must be centrally controlled by the UI, and the intense database activity involved in calculating decision parameters, a local installation of the ARIES application at USARC Headquarters was recommended. The development team believed it was critical to perform this type of testing at the actual client site in order to best measure the application’s performance in an operating environment that could not be simulated at NPS. Since this was economically infeasible, the application was rigorously tested on the provided laptop computer, and the burden of network “beta testing” of ARIES was shifted to the USARC staff.
D. SUMMARY

Our experience in using C2C to help USARC develop the prototype and test the SDSS concept, indicates that this approach can have a major impact on the way users and developers collaborate on producing functional software. C2C’s structural approach and use of component based development techniques to incrementally build and deliver mission-critical applications, formalizes a process that was, until recently, overly complex and unwieldy.

The C2C process puts an early emphasis on addressing a concept’s high-risk areas by rapidly prototyping a proof-of-concept version of the intended system that defines its specific component architecture. It does not assume a fixed set of user requirements at the concept inception, but allows for iterative refinement of the requirements as the project evolves. Changes are expected and accommodated. The main focus still remains the final software product and its quality, as measured by the degree to which it satisfies the user’s expectations.

As component-based development becomes more widespread and focuses on architecture, the complexity of the distributed operating environment should wane. Until that occurs, component-based systems built by non-programmers will probably continue to be interconnected in an unstable “hodge-podge” fashion. The best way to improve the integration of these systems is to adopt an enterprise-wide, integrated architectural strategy that incorporates standards that act to limit the inherent complexity faced by users and developers. In this sense C2C acts as a technological “gap filler” between baseline infrastructure and target applications.

As with any new software development process and modeling methodology, nothing works exactly right the first time out. The USARC-NPS innovative collaboration was no different. What appears to occur smoothly throughout the development of the
ARIES SDSS application, in retrospect was actually disjointed and haphazard as USARC and NPS personnel underwent a "learning experience" about merging component-based technologies with architectural thoughts and ideas. These "lessons-learned" are what the next chapter is devoted to exploring in detail.
IV. LESSONS LEARNED.

"There is a point at which methods devour themselves."
Frantz Fanon, Black Skins, White Masks, 1952.

“A tool knows exactly how it is meant to be handled, while the user of the tool can only have an approximate idea.”

“Reality is the murder of a beautiful theory by a gang of ugly facts.”
Robert L. Glass.

“The only thing new in the world is the history you have not learned.”
President Harry S. Truman

A. OVERVIEW.

This Chapter examines some of the most critical lessons that the development team learned while constructing the ARIES application. It is by no means inclusive of all the lessons learned during the project, but rather a representative sample of the lessons related to component-based development. Each chapter section is presented in categorical form, beginning with users and analysis; application development; rapid prototyping, and component-based development. Each of the pertinent lessons related to a particular section is stated first and then discussed at length.

B. CONCEPTUAL ANALYSIS AND THE USERS.

- Because of software development’s inherent malleability, it is difficult to anticipate which requirements will be implemented easily and which will decimate the project.

Deciding what to build and what not to build is the age old dilemma that faces all developers. Experience has proven that software requirements are the biggest impediment to properly engineering complex systems. Conventional as well as state-of-the-art software development practices have failed to make appreciable headway against
persistent and pervasive problems with requirements management (DON-NRL, 1996, p. 1). Beyond this need for discipline, requirements are intrinsically hard to define well. In an attempt to better manage requirements analysis, the development team countered with the Conceptualization Phase of the C2C Heuristic. By devoting crucial time and energy at the outset, we hoped to capture, structure, and contain the sheer essence of the project. This could not occur without an equal give-and-take on the part of the intended users. Through the formation of a collaborative effort, whereby the group built a little and prototyped a lot, a productive synergy yielded stable requirements from which to design architectures and model the problem domain. The users specify the “what” of the problem and the developers focus on the “how” of the solution. This iteratively and multiplicatively leverages the users’ business knowledge in concert with the technical acumen of the developers. Using prototyping as the practical solution, the cognitive layers and the feedback cycle of the C2C structure acts to progressively guide the collaborative ensemble en masse from high levels of abstraction to a specialized solution space.

In the case of ARIES, the characterization stage and U/I prototypes were the most instrumental in building the application correctly the first time instead of enduring endless cycles of change management. The developers were able to understand exactly what the SDSS needed to perform, were able to communicate side issues and discrepancies in the language of the users, and used an architectural focus to provide a means for controlling the production of the final application (DON-NRL, 1996, p. 6).

- **The developer cannot understand the business rules and processes well enough.**

Most application generation languages do a good job effectively designing the user interface and providing the underlying support code to connect the U/I to the pertinent database(s). But it is the business rules and data processing logic that are the
heart and soul of a successful application and are the most difficult to automate. It was this understanding of the rules to which the NPS development team devoted a majority of its analysis efforts. By focusing early in the Conceptualization Phase on thoroughly comprehending and characterizing the exact rules and processes used by the USARC decision-makers, the team avoided extensive and unnecessary rework later in the implementation stages. Using process roadmaps and documented business rules, ARIES development became a straightforward exercise in prototyping the U/I, identifying the required SQL database operations, linking the Rules to the U/I, and linking the rules to the SQL.

- *Keep the user engaged in the collaborative process.*

ARIES’s intended users failed to adequately specify top level system requirements as quantitatively as possible, and developers failed to better elicit them. Too many trade-offs and design decisions were left to the developer. Conflict at structured walk-throughs occurred between the developer’s view of the design and the users’ unarticulated view. Large amounts of development time were lost in several C2C stages because of these discrepancies.

Collaboratively prototyping in one room or meeting is difficult enough under the best conditions, but in the case of ARIES the development team resided at NPS in Monterey, California, while a majority of the time the users were at USARC headquarters in Atlanta, Georgia. Attempts to regulate the collaboration using email proved ineffective. A second problem in this arena involved the USARC LAN network software upgrade from Windows 3.1 to Windows NT which was not scheduled for completion until after product delivery. As a result, incremental prototype builds could only be alpha-tested by USARC decision-makers during the monthly progress meetings. Instead of stabilizing the design, the opposite outcome occurred as the prototype demonstrations
elicited user suggestions not anticipated by the developers. For example, the user wanted to be able to select the facilities for site relocation graphically using the mapping component. The development team mistakenly assumed that the map view should label the selectable nodes with its corresponding facility identifier (FacID). The Domain Prototype was built around this misconception, only to discover at the prototype demonstration that users had trouble “drilling down” through the map layers of the map view because they were in the habit of selecting facilities by the closest cities and towns rather than by FacID.

- **Identify who is responsible for software maintenance prior to development.**

One the biggest mistakes that can occur with regard to software development is to delay the selection of the software maintenance organization until after the development of the software application and data structure has begun. The developer may have deployed a superior application, but if is incompatible with existing infrastructures or unsupportable by the recipient organization’s IS support staff, then the program probably will not be used and likely “wither on the vine” from lack of support. The solution is to select the provider of the technical support prior to the commencement of application development. The IS support can be provided in one of two forms:

- Externally by the software development team/organization, or,
- In-house or organically (i.e., by an organization of the Army).

If an organic organization is selected, then the software tools and applications used for development must be provided to, and agreed upon, by the maintenance organization. In the case of ARIES, the initial Analysis Prototypes were developed using Borland’s Delphi 2.0 fourth generation language. Although the lead developer had experience with Delphi client-server environments, the USARC IS Staff were inexperienced and unfamiliar with the Delphi programming environment. Therefore
Delphi was summarily vetoed by the USARC IS Staff and two additional requirements were imposed in the second round of the Conceptualization Phase:

- Both the ARIES Application and Administer must be developed in Microsoft Visual Basic 4.0.
- All Visual Basic and MapBasic source code must be provided separately to USARC in an uncompiled form.

This resulted in a six week loss of development time while the development team attended several professional Visual Basic workshops and redesigned the Analysis Prototype to comply with these new requirements.

C. ARIES APPLICATION DEVELOPMENT LESSONS.

- *Small development teams are best.*

It is a fundamentally simple principle that if you want to limit the number of defects in a project, then limit the number of developers involved in producing the project. Good people produce good software (Yourdon, 1996, p. 28). The results from using a small team for the ARIES SDSS were better management, less coordination, and improved communication between both team members and users. By using a design heuristic, automated tools, and architectural structure, the development team was able to remain small in size (3-8 members), and reducing the amount of code to be written and tested. Small teams using modern tools, techniques, and user experience can achieve high levels of productivity.

- *Spatial selection, when properly implemented, can substantially reduce decision model parameter calculation response times.*

During the Visualization Phase, the domain prototype of the ARIES SDSS performed much more slowly than the collaborative team had anticipated. Some of the problems occurred because of overhead from complex SQL queries between the U/I and
the RDBMS. For example, calculating the available MOS’s from the closing Army Reserve units requires the following logic:

Determine all the individuals assigned to Closing Units who live within 50 miles of the Proposed Site having MOS’s matching a prospective Moving Unit’s requirement for a particular MOS.

The example took nearly an hour to execute on a Pentium 120 MHz computer, regardless of the population density of the location. Even with performance tuning execution time was still about 40 minutes on average to perform the query. The solution was to utilize the specialized geographic processing capability of the MapInfo component to spatially select only the database records within the 50 mile geographic boundary of the proposed site. This required obtaining a waiver from USARC to allow the development team to geocode the Army Reserve Unit personnel database (G18CWE) using the MARS Engine, to migrate the database, and to spatially enhance it and two others for geoquerying by ARIES. The performance gain from this technique was on the order of five to seven times faster (Figure 5-1).

- Avoid design error propagation by adhering to a philosophy of “Daily Build and Smoke Test.”

When discussing software development in terms of incremental prototypes or iterative “builds,” one thinks of monthly or weekly milestones. This correlates to the business world and our daily lives as a “normal” production pattern. The trouble lies in the rapid changes that prototyping perpetuates; factor in concurrent development by team members, and you have a recipe for disaster when project assembly occurs in one month (e.g., “let’s put it together and see what works”).
Figure 4-1. Spatial Solution Diagram.

Component-based development allows the developer to follow a different approach — the Daily Build and Smoke Test. This process can be used effectively for projects of any size or complexity and consists of developers, on a daily basis assembling, compiling, linking, building, etc., all the project components and code modules into a deliverable application and then testing to verify its basic operations. The team is not allowed to continue coding until the current "build" passes satisfactorily, and component failures can be attributed as the responsibility of the component creator. In this manner the developers start every day with a product that functions correctly, and
ensures that any defects that are present were induced within the last 24 hours. It is far easier to retrace an individual’s one day effort, than a team’s monthly effort. This prevents developers from unwittingly developing incompatible components and corrupting the overall design.

Why is this so important? The process pays for itself by reducing the time-consuming development risks of low quality, integration failure, and poor progress visibility (McConnell, 1996, p. 405). Not only does the developer always have a deployable application, but the users, project managers, and other team members always have a daily status of what is complete and what needs to be added. Any problems which arise tend to be relatively small in nature and can be dealt with accordingly, rather than shifting into “crisis mode” to rework code following a monthly or quarterly project build. “The daily build is the heartbeat of the project. It’s how you know you’re alive” (McCarthy, 1995).

- **A strong, stable, and well-defined architecture prevents degeneration of design.**

It can be extremely difficult to maintain an application architecture as the development process unfolds. Over time, performance and delivery pressures can combine to blur the architectural design, resulting in unwanted degeneration of the structure at all levels. A “good enough” architecture may be the result of attempting to accommodate a given COTS component structure, but a standards-based architecture is critical to the development process. Quality architecture is more likely to influence a successful project than a given set of components. Component technology and good architecture need to be intrinsically related, otherwise architectural mismatch can occur (Garlan et. al., 1995, p. 18). Rapid prototyping can accelerate this mismatch unless a strict development discipline is enforced by the developers to rework and revisit all affected components after each prototyping cycle ends and during component integration.
A well-thought out architectural solution can be effectively and efficiently implemented in almost any language, environment, and infrastructure.

D. RAPID PROTOTYPING LESSONS.

- Decide up front whether the prototype is to be a “throwaway” or a full production system.

A throwaway prototype or scaled-down model is used for feasibility exploration and proof-of-concept studies in which user requirements are incomplete and the system approach is uncertain. However, if a prototype is being constructed using known requirements, and only minor uncertainties remain regarding the system approach, then an evolutionary prototype can be built, in which some or all of the prototype is retained (Gordon and Bieman, 1995, pp. 85-86). Usually the throwaway is built first, with the developer proceeding quite rapidly as the user requirements are defined and the system architecture is confirmed. The downside is that, in its limited, scaled-down form, the prototype is usually incapable of being deployed as a full production system because so many shortcuts have been taken to illustrate whether something could be done. When the design specifications are complete, then it can be rewritten to fulfill a more flexible, scaleable, and extensible form.

Originally ARIES was budgeted for a two-phased development: a stand-alone throwaway prototype, and a full production network-centric version. The network model was to be a three-tiered, fully object-oriented client-server application that would be Windows NT enhanced to maximize decision parameter calculation using remote OLE automation. Difficulties with this scheduled arrangement occurred when project funding was reprogrammed halfway through the C2C development cycle. This required a collaborative reorganization of the ARIES SDSS to enable the application to execute in the network environment without being optimized for it.
Conventional wisdom counsels that whether “[you] plan to throw one away; you will anyway,” (Brooks, 1987) but often, in the interests of time and expense, a prototype will be retained in some form from the start. As developers we are not advocating one particular method over another, only that in the best interests of the collaborative design team, it is imperative to decide from the outset which one it will be.

- The collaborative nature of prototyping requires more of the user’s time than he plans for.

The challenge of managing a prototyping effort can be much more complicated than managing conventional software development. The difference stems from the heavy emphasis placed on providing the users what they want and need. This leads to modeling processes in new ways, which in turn requires near constant feedback to prevent wasted effort and trivial pursuits of unintended features. Sometimes this constitutes more feedback than the user is capable of providing.

Because USARC could only review U/I prototype once a month during their trips to NPS, user feedback tended to come very late in the prototyping cycle. This latency meant constructive feedback came at a time when incorporating the changes incurred significantly higher costs. Changes in the user interface prototype at the end of each Visualization Phase walk-through twice resulted in an additional four weeks of design, testing, and unit integration.

- Quick visual results encourages the user(s) to suddenly see possibilities where before they had only seen barriers.

A striking phenomenon about visually-oriented prototypes is the uncanny ability to elicit Archimede’s “Eureka!” reactions from the pool of intended users. The potential end-user goes from a position of “I’ll know it when I see it,” to “if you can do that, then surely you should be able to do this?” It provides a sense of empowerment to the user and allows him to shape and envision the final system., In practice however, this can only
occur after he has gained some experience from the system proposed by the developers (Gordon and Bieman, 1995, p. 86). As with every new unprecedented capability, there comes a dark side. The user’s hunger for more and more functionality can become insatiable without some outside restraint imposed by the development team. This may result in uncontrolled “requirements creep.” Because the prototype can so effectively and easily mirror the final system, the intended user(s) may have little sense of the relative costs and the diminishing marginal returns of adding functionality beyond the scope of the initial concept. In short, “perfection” becomes the enemy of “good-enough.”

In this sense it is the duty of the developers to guide and assist the users in prototyping the final system around a reasonable bandwidth of the users’ stated goals. Their experience and objectivity are critical in knowing when to stop prototyping and start coding. Otherwise excessive gold plating may result in a great system that never gets built.

- **Using COTS products does not eliminate software maintenance.**

On the contrary, because the origin of installed components is external to the developers, software maintenance plays an even larger role than it does in conventional software product development. If a component is modified and the vendor releases a bigger and better version, as they always do, who then is responsible for the care and feeding of the application? The vendor? The development team? The recipient organization? Secondly, if the developers use the product “as-is” and the vendor updates other components in the application architecture, who bears the brunt of the burden to ensure component compatibility? Each change in the implemented design requires a new version of the system to maintain the technical integrity of the application. Otherwise the incompatibilities become cumulative and propagate instability throughout the component architecture.
This was the case with LDW, the ARIES DSS component. As the other components received major product upgrades, including the operating system, the LDW DSS remained unchanged. Because of the unwillingness of the LDW vendor to migrate LDW to a 32-bit application, the burden of maintaining the ARIES product over the next 18 months will become even more difficult without radical work-arounds to make a 16-bit program backwards compatible within a 32-bit component framework. As a result, the viability of ARIES will become less and less certain as USARC upgrades its infrastructure.

In summary, you cannot simply build a component-based application and then forget about it. The more easily such an application is built, the more critical the maintenance effort needed over the application’s lifecycle.

E. COMPONENT-BASED COMPUTING LESSONS.

- Building custom components is really, really, hard.

Do not be fooled by the component evangelists. It is very difficult and time consuming to build even simple components that work and communicate well with other components and applications let alone complex ones. In today’s dynamically complex event-based development environments, a developer must be able to anticipate every possible use and interaction a component could be expected to fulfill and undergo respectively. Many component building and application software packages have been created to address these issues, but testing components in infinitely diverse combinations is a Herculean undertaking. Further, using contemporary methodologies does not insure success; many dismally poor components have been produced using modern tools and techniques. High quality and reliability comes at a premium cost. It is far easier to buy and modify a well-designed COTS product than to develop and validate a custom built one. The challenge in doing this well is to know and understand thoroughly the available
off the shelf commercial products, because many of the problems encountered during implementation simply cannot be determined before integration begins.

- *The learning curve for mastering component-based application development is steep.*

It is important that, prior to using a particular component or fourth generation development language for developing a component-oriented application, the developers are comfortable and familiar with the product. One person cannot be expected to instantly master several different components well enough to be an effective and efficient developer while at the same time attempting to prototype the system. “Just in time learning” is insufficient to guarantee a stable design and is often a blueprint for disaster.

- *Component communication protocols are the weakest link in the development chain.*

Some components are capable of using open or de facto standards (e.g., OLE), some must utilize proprietary communication protocols (e.g., DDE), and others cannot operate with various components at all. In order to effectively implement the ARIES component framework, the developers were forced to use a combination of all three methods to achieve the desired functionality. This approach was not without its drawbacks, for the less ‘open’ the protocol, the less functional the implementation. For example, because LDW is incapable of importing most current file formats, Microsoft Excel had to be used to save the resultant scenario’s decision parameter matrix in a tab-delimited format that LDW could process; Visual Basic could not do that easily. This introduced another component in the architecture whose only function was to serve as a file transfer agent, a function which is not the component’s strongest suit.

The MapInfo component, on the other hand, fully embraces the de facto OLE standard and effectively documents the component’s interconnections. As a result, approximately ninety percent of the functionality within the MapInfo application could be
done within an integrated map window. To similarly manipulate the LDW application, the ARIES U/I hypnotized it into executing user-simulated keyboard commands using Microsoft Windows API routines and macro scripts. Essentially the ARIES U/I tricked the program into thinking a user was present when he was not. This technique is strictly limited in that only about 20% of LDW’s capability could be controlled in this way by ARIES.

- Use of Commercial-Off-The-Shelf (COTS) components can result in “dead code” solutions.

In some cases the use of an appropriate or inappropriate component can result in some or most of the component’s functionality not being used (dead code). Essentially a large component with many capabilities may only be needed to provide a single function or a small subset of the original functionality. An example of this is the use of Microsoft Excel, a large and complex application for spreadsheet manipulations, which is used exclusively in ARIES to load the decision parameter matrix and save it in a different format. Similarly, MapInfo is used only for geoquerying and facility selection, in spite of its extensive thematic mapping capability. The resources that the mapping component consumes (e.g., 4 MB of random-access memory) are lost to other applications when only 15% of the component is used.

- COTS components are not all “open” standard compliant.

This was probably the hardest lesson the ARIES development team had to contend with, and is a major issue for anyone interested in pursuing component-based development as a solution provider. In the past components or small, specialized 16-bit applications were designed and built using proprietary standards combined with programmers’ idiosyncratic methods to achieve a certain level of performance. As operating systems have matured and become more sophisticated, components and
programs are able to take advantage of object libraries and infrastructure to achieve functionality. Yet openness is still measured by proprietary designs and consumer acceptance. Providing a uniformly understandable means for accomplishing tasks is key to limiting communication chaos and reducing risk within the application's architecture. Without standardization and architecture, the process of integrating unique application components becomes extraordinarily complex. Since no single vendor has accommodated the entire range of infrastructure management needs, de facto standards have emerged.

This is where the real trouble arises, for third-party components and updates from vendors are not exactly ‘plug and play’, and frequently have a tendency to be falsely documented. The integration of various component data formats and communication protocols can be very complex, and subtle “gotchas” within a component may render its role in the component framework null and void. Initially the development team tried to grab too much “off the shelf” and hastily put it all together during the prototyping stages. This yielded mixed results — mostly bad. The team was so enamored by the prospect of a buy-and-integrate strategy that it failed to realize that some COTS products can only interact in accordance with its own set of standards, architectures, and design. Not all COTS products are universally pliable. They may require in depth analysis of their intended operating environments and structure.

As an example, LDW is capable of screen capturing its various graphic analysis displays to the clipboard or a graphic file. The undocumented difficulty is that the “clipboard” was implemented by the programmer in C++ without using Windows native API routines. Additionally, the graphic file is the 16-bit Windows meta-file standard (WMF) that is supported by only a handful of programs (e.g., Microsoft PowerPoint). Therefore, the only method available to allow the user to personalize the standard reports
feature of the ARIES U/I was to implement another large "dead-code" component, like PowerPoint, to once again act as a file transfer agent for graphic analysis editing. Another difficulty emerges when trying to integrate new versions of existing components within the application's architecture. The new version may have a different look-and-feel and require more memory, and/or previous data formats and protocols may no longer be supported. In any case, another C2C incremental cycle will need to be completed to ensure application compliance and functionality.

The only way in which to make various disparate components operate together reliably is to adopt a strong single vendor infrastructure solution (Microsoft) and work within the confines and limitations inherent to the selected standards and architecture. Hopefully in the future, emerging software technologies will be developed and distributed as a new kind of component. A component that is functionally cohesive, based upon open standards, small in terms of complexity, and therefore capable of operating in conjunction with all other possible components and software applications. (Figure 5-2).

F. SUMMARY.

It is becoming increasingly clear that software development, which relies heavily upon component-based architecture, requires modifications to the traditional development methodologies. Although some of the lessons derived from ARIES were recurring themes of software developments lessons of the past recast in component-based form, others were unique to the particular technologies and methods used within the structured C2C paradigm. In the final chapter, we summarize the lessons learned from this SDSS exercise, and project how these can be adapted to future component-based development applications.
Figure 4-2. Component Evolution Diagram.
V. CONCLUSIONS AND FUTURE RECOMMENDATIONS.

"Institutionalizing organization-wide decision-making processes and an architecture is the key to all of our information system development efforts...and our primary measure of success is impact on the bottom line."
Chief Information Officer (GAO, 1994).

"It is generally very difficult to keep up with a field that is economically profitable, and it is only natural to expect that many of the techniques described here will eventually be superseded by better ones."

"We build systems like the Wright brothers built airplanes — build the whole thing, push it off a cliff, let it crash, and start over again."

A. INTRODUCTION.

This chapter synopses the underlying themes characterizing the development and implementation of the ARIES SDSS. It summarizes our experience with using the Concept-to-Code (C2C) design heuristic to construct software within the context of a new structured paradigm, and provides suggestions and insight into the ARIES Next Generation (NEXGEN) prototypes.

B. LOOKING BACK.

Reflection upon the ARIES SDSS implementation could be perceived in one of two ways: as "blind luck", a one-time-success story that by sheer happenstance delivered exactly what the user wanted with a development team that had no prior experience with the underlying development tools; or, in a more realistic light, as an application which provided a means to explore, justify, and demonstrate the validity of using component-based computing in conjunction with rapid application development techniques, to

81
quickly and accurately produce a scaleable, extensible, and useful decision support application.

The C2C design heuristic employed for ARIES allowed the collaborative team to quickly conceive and sketch screens and displays, and then build the user interface up front in a short turnaround period. Defining how the components of the application architecture were to communicate with one another, drove how the intended functionality of the architecture was to be accomplished. The heuristic allowed the developers to “architect” the system into small components and put the high risk segments (e.g., primary functionality) at the head of the prototyping line, rather letting them slip to the end. It was important to build the most difficult components first and then add the “nice-to-haves” later on. C2C also greatly improved management oversight by allowing the application development process to be layered from a generic concept to specialized solution.

In summary, the C2C process has resulted in a number of benefits:

- Facilitated understanding of the development process by managers and programmers using a one-page graphical representation.

- Provided concise, definable phases with clear entry and exit criteria and staged iterative development.

- Fostered an atmosphere of continuous quality process improvement between users and developers.

- Allowed small development teams to implement large scale, complex applications in short development cycles.

- Provided clear communication of project status between the development team and management on a daily basis.

The success of the ARIES SDSS could be considered surprising, but in reality it was no fluke. The C2C process, applied carefully, can lead to powerful applications within a surprisingly short period of time, months vis-à-vis years as in the case of ARIES.
Undoubtedly, C2C will continue to undergo experimental refinement and improvement, as it may very well become the mainstay of software application development.

To date, the ARIES SDSS is effectively deployed on the USARC local area network, as well as USARC staff officers’ laptop computers. The results of the ARIES SDSS deployment have been very positive for both the NPS development team members and the USARC staff. The issues of timely and consistent response to site relocation questions appear to be more than adequately met by the ARIES SDSS prototype.

C. LOOKING FORWARD.

   a. Infrastructure: A Component Update

   In the short time since the deployment of the ARIES SDSS prototype on the USARC LAN, several changes have occurred with its primary components. All of the COTS infrastructure components, with the exception of Logical Decisions for Windows, have had new versions released by their associated vendors. Each component’s functionality has been greatly enhanced and conforms to widely accepted client-server protocols. This includes the Visual Basic development language, which has been significantly upgraded to function exclusively within the component-based paradigm. Applications created in Visual Basic 5.0 are now fully compilable and the ODBC component has been integrated into the new JET SQL 3.5 RDBMS engine. If ARIES code were migrated unchanged to the new 4GL environment, the user could expect to see an approximate 20% increase in program execution time and a dramatic
increase in non-native data processing time. This would also greatly reduce the time required to build the data migration warehouse from USARC’s FoxPro 2.0 data sources.

MapInfo and MapBasic have also been improved, however, the vendor has also created a separate integrated mapping component, called MapX, based on the Microsoft ActiveX standard. MapX allows developers to directly compile the desired mapping functionality with the prototyped application, thus eliminating the need for OLE communications between the two components. The integrated mapping features can now be “hardwired” directly into the ARIES U/I and would only need a fourth of the computer memory currently used by the MapInfo application.

b. ARIES DSS Component Redesign: The Need for Innovation

The current version of LDW in its 16-bit format, is still more than capable of providing the required functionality, but as USARC upgrades its IT infrastructure to take advantage of future technology, the ARIES DSS component in its unscaleable form, will eventually fail to provide effective decision support. What is needed is a new scaleable and extensible 32-bit DSS component. Currently, there are no vendors marketing DSS software with all of the functionality of the 16-bit LDW application (e.g., automatic waiting, dynamic sensitivity, etc.) The difficult choice is to either wait for market conditions to change, or custom develop a similar DSS component with the following additional features:

- Allow the decision model to be directly manipulated within an integrated window on the ARIES U/I.

- Allow decision-makers to graphically add or delete new decision parameter nodes, as well as fully document how they are calculated.

- Create a Report Manager that allows the user to drag-and-drop various decision model graphs into standard documents (e.g., Microsoft Word, HTML, etc.)
c. *Migrate Decision Making to the Web*

In order to take advantage of USARC's upgraded Windows NT operating system and the continued focus on network-centric infrastructure; the competent developer can use the Visual Basic 5.0 component creation tool to build a new ARIES component that separates the USARC business rules and decision parameter calculations from the user interface. By using ActiveX technology, the ARIES SDSS can truly be a three-tier client-server application. The rules and processes could be changed, updated, or added separately from the ARIES U/I while still in accordance with corresponding changes in the ARU-Decision Model. Development time can now be better spent elsewhere instead of redesigning the U/I every time a business rule or condition changes.

The new Visual Basic development language also allows the developer to "web-enable" any application quickly and easily from within the 4GL environment. The ARIES U/I could now be rapidly prototyped within a common development environment by the collaborative team in less time, using a web browser (e.g., Netscape Navigator or Microsoft Explorer) and a point-and-click web page designer (e.g., Adobe PageMill or NetFusion). This would allow ARIES to use more of USARC's stabilized infrastructure, reduce the amount of software maintenance support needed, and reduce the number of languages and development tools that the application developer must learn.

2. *Future Technology Options.*

An important concern is how far the process of simplification of the user interface should go to provide easy access to spatial information without sacrificing necessary functionality. Prototyped software that enables site selection across space and time using a component-based infrastructure like the ARIES SDSS, has been created as one small step towards the continued development of spatial decision support systems. Thanks to
new component-based software tools, it is now possible to create compact, yet specialized web-based applications that allow inexperienced users to participate to a greater extent in solving local, spatially orientated problems as decision-makers rather than as programmers. This is all desirable as far as it goes, but without changes to other peripheral issues, the future capabilities of the ARIES NEXGEN cannot only advance so far. The USARC business processes related to site selection decisions are ripe for a concentrated reengineering effort that has the future in mind — Visioneering.

a. Data Source Management

The underlying data management philosophy of the NEXGEN SDSS is that the entire USARC network, local and remote sites, comprise a single, large virtual “Resources-to-Readiness” data migration warehouse. The decision-maker should be able to access any and every data source relating to site selection whether on an Army Reserve mainframe in Washington D.C., or a spatial data server on the local LAN; all from within the browser U/I. In today’s network-centric ecosystem, it makes good sense to use the web as an operating desktop since it is a logical interface that most users can quickly learn and understand. Essentially, the NEXGEN is a network user interface (NUI), whereby the user is able to seamlessly apply business rules and calculate decision parameters without having to have knowledge of where the data actually resides.

The NUI will improve database processing by leveraging the flexibility of the web middleware to pull data simultaneously from all local and mainframe data stores using open standards. In short, web-based technologies act as a “data resolver” to connect decision-makers to information no matter where it is stored or how it is structured (Joch, 1997, p. 104D).
b. **Decision-Maker Knowledge Management**

In order to adapt to the continuous turnover of military personnel at USARC headquarters, the NEXGEN SDSS needs to be able to interactively model and capture the corporate knowledge about various data sources, business rules, and ad-hoc queries residing in the minds of the decision-makers. When stored and replicated, this meta-data knowledge becomes a reusable resource that ensures a given decision analysis can be based on repeatable findings. In short, this means knowledge management through automation.

c. **Decision Parameter Derivation in Parallel**

Although new technologies and software are produced everyday, the appetite for higher application performance is never satiated. The sequential calculation of ARIES decision parameters using spatial selection was a superior solution for mobile decision-makers, but within the NT ecosystem, parallelism is an even better solution. The NT network supports this by near simultaneous launching of remote automated OLE server objects for decision parameter computations onto the network. In this scenario, the idle processors of any desktop computers attached to the network can be utilized to calculate all the decision parameters essentially in parallel. Depending on the amount of network traffic present, the entire decision parameter matrix could be hypothetically calculated in the same amount of time it now takes to complete just one complex decision parameter query.

3. **Future Scenario: The Final Episode.**

Users want to shape the technology that is implemented in their organization. They want to control its use and determine the effect it will have on their own work. They are rapidly understanding that their
effective use of technology coupled with a change in how they do business will determine their personal and organizational success. (Tapscott, 1993, p. 14)

As component-based computing becomes more and more the norm for application development within civilian and military organizations, developing future IT decision support systems may become a far easier and user-friendlier process. Just ask Colonel McMurdо about his ARGIS 21 system:

1721 HRS: “Hey Jack! That ARGIS 21 product is your responsibility, right?” It was Brigadier General Mark Rutherford, Col. McMurdо’s immediate boss, on the phone.

“Yes Sir,” the Colonel replied.

“Well the Old Man just got a call about the BRAC situation on CNN. After that 'stick-save' at the hearing today, you’re stock is up 20 prestige points. As a matter of fact, you have a meeting with the Chairman and the other Four Stars in the Tank first thing tomorrow morning Seems they have big plans for ARGIS 21 concerning better force dispersion, limited over-the-horizon target selection, and real-time Joint logistics shipping status. You’d better bring that laptop of yours.”

“I’m on it, Sir,” McMurdо responded, “and while I’m at it, I’d better give those people back at NPS a call. Looks like we’re going to be quite busy.”
APPENDIX A.  ARIES SOURCE DATA FILE META-DATA.

This appendix contains the meta-data that was documented for the ARIES SDSS prototype data source files. "ACROPOLIS" as used in this appendix refers to the file name of the ARIES data migration warehouse (DMW).

APPENDIX B.  ARIES BUSINESS RULES AND PROCESSES.

This appendix contains detailed information about the calculation of each ARU-Decision Model parameter that was automated in the ARIES SDSS prototype application. The information includes a description of each decision parameter, the business rule used to calculate the associated value, base units, source files, associated data migration warehouse (ACROPOLIS) tables, query or queries involved in the calculation, a description of the yield curve, and a graph of the yield curves. “ACROPOLIS” is the file name for the ARIES data resource file.

The term “in the area” in this Appendix is defined as being with in a 50-mile radius of the moving unit or proposed facility.

Index

Decision Parameter 1. Facility Backlogged Maintenance .............................................127
Decision Parameter 2. Facility Operating Costs ..........................................................129
Decision Parameter 3. Facility Age .............................................................................131
Decision Parameter 4. Facility Condition .................................................................133
Decision Parameter 5. Facility Ownership ...............................................................135
Decision Parameter 6. Competition .......................................................................137
Decision Parameter 7. Average Area Drill Attendance ............................................139
Decision Parameter 8. Area Loss Rate .......................................................................141
Decision Parameter 9. Area Transfer Rate ...............................................................143
Decision Parameter 10. Area Average Manning ......................................................145
Decision Parameter 11. Distance to Nearest Recruit Station ....................................147
Decision Parameter 12. Available Transfers from Closing Units ...............................149
Decision Parameter 13. IRR Available .....................................................................151
Decision Parameter 14. Recruit Market ...................................................................153
Decision Parameter 15. Reassignments ....................................................................155
Decision Parameter 16. Distance to Area Maintenance Support Activity ...................157
Decision Parameter 17. Distance to Nearest Equipment Concentration Site .............159
Decision Parameter 18. Facility Weekends Used .....................................................161
Decision Parameter 19. Available MOS from Closing Units ....................................163
Decision Parameter 20. Available MOS IRR ............................................................167
Decision Parameter 1. Facility Backlogged Maintenance

Definition: Facility Backlogged Maintenance provides the total dollar value of backlogged maintenance. This provides an indication of the initial investment required to correct the significant maintenance problems with a proposed facility.

Calculation: The Backlogged Maintenance value is based upon the sum values for maintenance actions documented for each facility in the “CWE_TOTAL” field of the RPINFOODT file. The summation is done during the data extraction phase.

Maint_Cost[Sum of outstanding maintenance actions for a facility]

Units: Dollars

Source File: RPINFOODT

ACROPOLIS Table(s): RPINFOODT

Query: Maint_Cost
SELECT MAINT_COST
FROM RPINFOODT
WHERE RPINFOODT.FACID = ProposedFacility.FAC_ID

Yield Curve: A linear relationship is assumed between the backlogged maintenance costs and utility. Every dollar required or saved in this category is expected to have equal utility to a relocating unit.

Max Utility: 0 Min Utility: 1,000,000
DECISION PARAMETER 2. Facility Operating Costs

**Definition:** Facility Operating Costs provide an indication of the financial resources that are required to maintain the facility in a serviceable condition. This includes both utilities and minor maintenance costs.

**Calculation:** Operating Costs are extracted from the “COST_PR_SF” field of the FPS file.

\[
\text{COST_PR_SF}[\text{Retrieve the Cost per Square Foot for a facility}]
\]

**Units:** Dollars per square foot per month

**Source File:** FPS

**ACROPOLIS Table(s):** FPS_

**Query:**

```sql
SELECT COST_PR_SF
FROM FPS_
WHERE FPS_FACID = ProposedFacility.FAC_ID
```

**Yield Curve:** A linear relationship is assumed between the operating costs and utility. Every dollar required or saved in this category is expected to have equal utility to a relocating unit.

![Graph showing linear relationship between utility and dollars/square foot per month]

Max Utility: 0
Min Utility: > 100
Decision Parameter 3. Facility Age

Definition: This Decision Parameter indicates the age of the primary structure on the proposed relocation site. It is intended to reflect an assumed long term structural degradation with time.

Calculation: Facility age is calculated based upon the acquisition date found in the INTEREST file. The acquisition date is compared to the current date and the difference is determined in months.

\[ \text{DATE\_ACQ} \times (\text{Current Year} - \text{Date Acquired}) \]

Units: Months

Source File: INTEREST

ACROPOLIS Table(s): INTEREST

Query:

\begin{verbatim}
SELECT DATE\_ACQ
FROM INTEREST
WHERE INTEREST\_.FACID = ProposedFacility.FAC_ID
\end{verbatim}

Yield Curve: A linear relationship is used between facility age and utility.

Max Utility: 0 Min Utility: > 1,200
THIS PAGE INTENTIONALLY LEFT BLANK
Decision Parameter 4. Facility Condition

**Definition:** Facility Condition is based upon a visual inspection of the structure and provides an indication of the serviceability of the primary structures.

**Calculation:** This Decision Parameter is based upon the ISR part 1 rating entered in the "FAC_COND" field of the FPS file.

FAC_COND[Retrieve Facility Condition]

**Units:** No Units (Green, Amber, Red)

**Source File:** FPS

**ACROPOLIS Table(s):** FPS_

**Query:**

```
SELECT FAC_COND
FROM FPS_
WHERE FPS_FACID = ProposedFacility.FAC_ID
```

**Yield Curve:** The utility of these three categories varies in discrete steps. A facility that is categorized as “green” is judged to be approximately twice a desirable as one that is assigned an “amber” rating.

![Utility Chart]

**Max Utility:** GREEN  
**Min Utility:** RED
Decision Parameter 5. Facility Ownership

**Definition:** This Decision Parameter indicates whether the facilities at a proposed relocation site are leased or owned.

**Calculation:** Facility Ownership is based upon the entry in the "GOVT_OWNER" field of the COMPLEX file.

```
GOVT_OWNER[Retrieve Ownership Status]
```

**Units:** No Units (Yes/No)

**Source Data:** COMPLEX

**ACROPOLIS Table(s):** COMPLEX_

**Query:**
```
SELECT GOVT_OWNER
FROM COMPLEX_
WHERE COMPLEX_FACID = ProposedFacility.FAC_ID
```

**Yield Curve:** Facilities that are owned by the government are preferred as relocation sites over those facilities that are leased. The owned sites are assigned the maximum utility value of 1.0, while leased sites are given a 0 utility score.

![Utility Chart]

- **Max Utility:** Yes
- **Min Utility:** No
**Decision Parameter 6. Competition**

**Definition:** This Decision Parameter provides an indication of the level of competition for potential reservists. It considers only Army Reserve and Army National Guard units in the area of the relocation site.

**Calculation:** Competition is determined by the number of positions that must be filled by all other Army Reserve and Army National Guard (ARNG) units in the area of the proposed relocation site. For Army Reserve units, the number of required positions is determined by counting the number of records in the G19TRUE file associated with each UIC in the area. For ARNG units, the value is found in the "AUTH" field of the NGNON_CL file.

\[
\text{NO\_AUTH\_NG}[\text{Number Authorized National Guard}] + \\
\text{NO\_REQD}[\text{Number Area Reservists Required}]
\]

**Units:** Number of competing positions

**Source File:** COMMAND PLAN, G17, G19TRUE, GEOREF, NGNON_CL

**ACROPOLIS Table(s):** CMDPLAN, G17Natl, G19Natl, VALID_UIC

**Query:**

Area-FACID List(MapInfo)

```
SELECT FAC_ID INTO TempFACID
FROM GEOREF
WHERE Object Within ObjAreaBuffer
ORDER BY FAC_ID
(Note: ObjAreaBuffer is equal to 300 miles)
```

```
VALID_UIC
SELECT UIC, FAC_ID, UnitName, City, State, Zip
FROM G17Natl
WHERE G17Natl.UIC = ANY (SELECT CMDPLAN.UIC
FROM CMDPLAN)
```

```
Area-UIC List
SELECT DISTINCT UIC INTO AREA_UIC
FROM VALID_UIC
WHERE VALID_UIC.FAC_ID = ANY (SELECT AREA_FACID.FAC_ID
FROM AREA_FACID)
```

```
NO\_AUTH\_NG(MapInfo)
SELECT * INTO TempNGUnits
FROM NON_CLOS
```

137
WHERE Obj Within ObjAreaBuffer

SELECT SUM(AUTH) "No_AUTH_NG" INTO Strength
FROM TempNGUnits

NO_REQD
SELECT SUM(UIC_TOTAL) AS TOTAL_REQD
FROM G19Natl
WHERE G19Natl.UIC = ANY (SELECT AREA_UIC.UIC
FROM AREA_UIC)

**Yield Curve:** A linear relationship exists between the number of competing positions from other units and the utility of a relocation site. The level of no site utility in this Decision Parameter begins at 10,000 positions which is above the maximum value expected.

Max Utility: 0      Min Utility: > 10,000
Decision Parameter 7. Average Area Drill Attendance

Definition: This Decision Parameter indicates the fraction of reservists with satisfactory drill attendance for all existing units in the area of the proposed relocation site. Areas with a high fraction of satisfactory drill attendance are preferred relocation sites because units relocated to that area are assumed to perform similarly in drill attendance.

Calculation: This Decision Parameter considers the last four quarters of data contained in the FINANCE file. After initial screening, the number of reservists with 21 or more drill periods for the year is divided by the total number of people who meet the screening.

\[
\frac{\text{DRILL\_SAT}}{\text{DRILL\_TOTAL}} = \frac{\text{Number of reservists with > 21 drill periods in a year}}{\text{Number of reservists required to drill}}
\]

Units: Ratio

Source File: COMMAND PLAN, FINANCE, G17, G19TRUE, GEOREF

ACROPOLIS Table(s): CMDPLAN, FINANCE_, FINANCE_QTR, G17Natl, G19Natl, VALID_UIC

Query:

Area-FACID List(MapInfo)

```sql
SELECT FAC_ID INTO TempFACID
FROM GEOREF
WHERE Object Within ObjAreaBuffer
ORDER BY FAC_ID
(Note: ObjAreaBuffer is equal to 300 miles)
```

VALID_UIC

```sql
SELECT UIC, FAC_ID, UnitName, City, State, Zip
FROM G17Natl
WHERE G17Natl.UIC = ANY (SELECT CMDPLAN.UIC
FROM CMDPLAN)
```

Area-UIC List

```sql
SELECT DISTINCT UIC INTO AREA_UIC
FROM VALID_UIC
WHERE VALID_UIC.FAC_ID = ANY (SELECT AREA_FACID.FAC_ID
FROM AREA_FACID)
```
FINANCE_CY
SELECT UIC, COUNT(UIC) AS UIC_TOTAL INTO FINANCE_CY
FROM FINANCE_QTR
WHERE (Select Case)
    Case 1st Qtr FY
        (UTA1Q1PF + UTA2Q1PF + UTA3Q1PF + UTA4Q1PF) > 20
    Case 2nd Qtr FY
        (UTA2Q1PF + UTA3Q1PF + UTA4Q1PF + UTA1QCFY) > 20
    Case 3rd Qtr FY
        (UTA3Q1PF + UTA4Q1PF + UTA1QCFY + UTA2QCFY) > 20
    Case 4th Qtr FY
        (UTA4Q1PF + UTA1QCFY + UTA2QCFY + UTA3QCFY) > 20
GROUP BY UIC
ORDER BY UIC

DRILL-SAT
SELECT SUM(UIC_TOTAL) AS TOTAL_SAT
FROM FINANCE_CY
WHERE FINANCE_CY.UIC = ANY (SELECT AREA_UIC.UIC
                                      FROM AREA_UIC)

DRILL-TOTAL
SELECT SUM(UIC_TOTAL) AS DRILL_TOTAL
FROM FINANCE_
WHERE FINANCE_.UIC = ANY (SELECT AREA_UIC.UIC
                                      FROM AREA_UIC)

Yield Curve: The utility of the average drill attendance rate increases linearly between the values of 0 and 0.6. Above that point, increases in the attendance rate result in diminishing returns. Values above 0.6 become increasingly uncommon.

![Utility Graph]

Max Utility: 1.0        Min Utility: 0.0
Decision Parameter 8. Area Loss Rate

Definition: This Decision Parameter indicates the fraction of reservists who left the reserves in the previous fiscal year, for all existing units in the area of the proposed relocation site. Areas with a low loss rate are preferred relocation sites because units relocated to that area will also experience low loss rates.

Calculation: The number of losses to units in the area in the previous fiscal year is divided by the number of reservists currently assigned to these units. Losses are identified through the transfer mnemonic field (TRMN="LOSS") of the FyxxLOSS file. The number of assigned reservists is determined by counting all of the personnel records in the G18CWE file associated with each UIC in the area.

\[
\frac{\text{NOLOSS[	ext{Total Number of Losses in the last year}]} }{\text{NOASSN[	ext{Total Number Reservists Assigned}]} }
\]

Units: Ratio

Source File: COMMAND PLAN, FYxxLOSS, G17, G18CWE, GEOREF

ACROPOLIS Table(s): CMDPLAN, FYxxLOSS, G17Natl, G18NatUIC, VALID_UIC

Query:

Area-FACID List(MapInfo)
SELECT FAC_ID INTO TempFACID
FROM GEOREF
WHERE Object Within ObjAreaBuffer
ORDER BY FAC_ID
(Note: ObjAreaBuffer is equal to 300 miles)

VALID_UIC
SELECT UIC, FAC_ID, UnitName, City, State, Zip
FROM G17Natl
WHERE G17NatUIC.UIC = ANY (SELECT CMDPLAN.UIC
FROM CMDPLAN)

Area-UIC List
SELECT DISTINCT UIC INTO AREA_UIC
FROM VALID_UIC
WHERE VALID_UIC.FAC_ID = ANY (SELECT AREA_FACID.FAC_ID
FROM AREA_FACID)

NO_ASSN
SELECT SUM(UIC_TOTAL) AS TOTAL_ASSN
FROM G18NatUIC

141
WHERE G18Natl_UIC.UIC = ANY (SELECT AREA_UIC.UIC FROM AREA_UIC)

NO_LOSS
SELECT SUM(UIC_TOTAL) AS TOTAL_LOSS
FROM FYxxLOSS
WHERE FYxxLOSS.UIC = ANY (SELECT AREA_UIC.UIC FROM AREA_UIC)

**Yield Curve:** This function includes both concave and convex regions. The inflection point occurs at a loss rate of .33 and a utility of 0.5. Based on experience, a loss rate of one third per year was considered to be typical. Any loss rate below this value has relatively high utility, whereas loss rates above the inflection point quickly approach a utility of zero.

![Yield Curve Graph](image)

**Max Utility:** 0  
**Min Utility:** 1
Decision Parameter 9. Area Transfer Rate

Definition: This Decision Parameter indicates the fraction of reservists who transferred to different units in the previous fiscal year for all existing units in the area of the proposed relocation site. Areas with a low transfer rate are preferred relocation sites because units relocated to that area will also experience low transfer rates.

Calculation: The number of transfers in the previous fiscal year is divided by the number of reservists currently assigned to the unit. Transfers are identified through the transfer mnemonic field (TRMN="TRFD") of the FyxxLOSS file. The number of assigned reservists is determined by counting all of the personnel records in the G18CWE file associated with each UIC.

\[
\frac{\text{NO}_\text{XFER}[\text{Total Number of Transfers in the last year}]}{\text{NO}_\text{ASSN}[\text{Total Number Reservists Assigned}]}
\]

Units: Ratio

Source File: COMMAND PLAN, FYxxLOSS, G17, G18CWE, GEOREF

ACROPOLIS Table(s): CMDPLAN, G17Natl, G18Natl_UIC, FYxxXFER, VALID_UIC

Query:

Area-FACID List(MapInfo)
SELECT  FAC_ID INTO TempFACID
FROM    GEOREF
WHERE    Object Within ObjAreaBuffer
ORDER BY FAC_ID
(Note: ObjAreaBuffer is equal to 300 miles)

VALID_UIC
SELECT  UIC,  FAC_ID,  UnitName,  City,  State,  Zip
FROM    G17Natl
WHERE    G17Natl.UIC = ANY (SELECT CMDPLAN.UIC
                              FROM CMDPLAN)

Area-UIC List
SELECT  DISTINCT UIC INTO AREA_UIC
FROM    VALID_UIC
WHERE    VALID_UIC.FAC_ID = ANY (SELECT AREA_FACID.FAC_ID
                                  FROM AREA_FACID)
Yield Curve: This function includes both concave and convex regions. The inflection point occurs at a loss rate of .33 and a utility of 0.5. Based on experience, a transfer rate of one third per year was considered to be typical. Any loss rate below this value has relatively high utility (close to 1.0), whereas loss rates above the inflection point quickly approach a utility of zero.

Max Utility: 0  Min Utility: 1
Decision Parameter 10. Area Average Manning

Definition: This Decision Parameter indicates the ability to fill the required positions. An average value is determined for all existing units in the area of the proposed relocation site. Areas with high average manning levels are preferred relocation sites because units relocated to that area will also experience high manning levels.

Calculation: The number of reservists assigned to area units (based upon the number of personnel records in G18CWE file associated with each UIC) is divided by the number of required positions (based upon the number of positions in the G19TRUE file associated with each UIC). An average is calculated for all UIC’s in the area of the proposed site.

\[
\frac{\text{NO_ASSN}[\text{Total Number Reservists Assigned}]}{\text{NO_REQD}[\text{Number Area Reservists Required}]}
\]

Units: Ratio

Source File: COMMAND PLAN, G17, G18CWE, G19TRUE, GEOREF

ACROPOLIS Table(s): CMDPLAN, G17Natl, G18Natl_UIC, G19Natl, VALID_UIC

Query:
Area-FACID List(MapInfo)
SELECT FAC_ID INTO TempFACID
FROM GEOREF
WHERE Object Within ObjAreaBuffer
ORDER BY FAC_ID
(Note: ObjAreaBuffer is equal to 300 miles)

VALID_UIC
SELECT UIC, FAC_ID, UnitName, City, State, Zip
FROM G17Natl
WHERE G17Natl.UIC = ANY (SELECT CMDPLAN.UIC FROM CMDPLAN)

Area-UIC List
SELECT DISTINCT UIC INTO AREA_UIC
FROM VALID_UIC
WHERE VALID_UIC.FAC_ID = ANY (SELECT AREA_FACID.FAC_ID FROM AREA_FACID)

145
NO_ASSN
SELECT SUM(UIC_TOTAL) AS TOTAL_ASSN
FROM G18Natl_UIC
WHERE G18Natl_UIC.UIC = ANY (SELECT AREA_UIC.UIC
FROM AREA_UIC)

NO_REQD
SELECT SUM(UIC_TOTAL) AS TOTAL_REQD
FROM G19Natl
WHERE G19Natl.UIC = ANY (SELECT AREA_UIC.UIC
FROM AREA_UIC)

Yield Curve: It is desirable that area units be able to exceed their minimum manning requirements. All manning levels above 125% are considered to have maximum utility. Manning levels below this value drop off quickly in terms of utility.

Max Utility: 1.25     Min Utility: 0
Decision Parameter 11. Distance to Nearest Recruit Station

Definition: Distance to the nearest Recruiting Station provides one indication of recruiter effectiveness.

Calculation: The straight-line distance from the proposed site to the closest recruiting station is calculated using a geocoded version of the RZA file.

\[ \text{DIST}_{\text{RZA}}[\text{Determine distance to nearest Recruit Station}] \]

Units: Miles

Source Data: RZA

ACROPOLIS Table(s): NONE

Query:

DIST_RZA(MapInfo)
SELECT * FROM RZA
WHERE Obj Withing ObjDistanceBuffer into TempRZA
(Note: ObjDistanceBuffer is equal to 300 miles)

SELECT Distance((CentroidX(Obj), CentroidY(Obj), FacIDLat, FacIDLong, "mi") FROM TempRZA
ORDER BY Distance INTO TempRZA.Dist

Yield Curve: The effectiveness of a recruiting station in filling positions at a reserve unit is fairly high if the two are within a half hour drive of each other. It is assumed that recruiters are most effective in the area close to their recruiting station and that reserve recruits must be located near the unit with which they will serve. A distance of 30 miles is assigned an average utility of 0.5. A small change in distance results in less change in desirability when the distance is very small or very large than it does when the distance is around 30 miles.

![Utility Curve Graph]

Max Utility: 0 Min Utility: > 100

147
THIS PAGE INTENTIONALLY LEFT BLANK
Decision Parameter 12. Available Transfers from Closing Units

**Definition:** This value indicates the total number of personnel assigned to closing units within 50 miles of the proposed site.

**Calculation:** A list of Unit Identification Codes (UIC’s) is created which contains only those units scheduled to close within 18 months. These units are identified by an entry of 5B in the “Tier” field of the G17 file. The number of potential transfers from closing units is calculated by summing the number of records in the G18CWE database for the closing units which are located in the area of the proposed relocation site.

TOTAL_AVAIL[Total Number of Available Reservists from Area Closing Units]

**Units:** Ratio

**Source File:** COMMAND PLAN, G17, G18CWE, GEOREF, US_ZIPS(MapInfo)

**ACROPOLIS Table(s):** CMDPLAN, G17Nat1, VALID_UIC

**Query:**

```
Area-FACID List(MapInfo)
SELECT FAC_ID INTO TempFACID
FROM GEOREF
WHERE Obj Within objAreaBuffer
ORDER BY FAC_ID
(Note: objAreaBuffer is equal to 300 miles)

VALID_UIC
SELECT UIC, FAC_ID, UnitName, City, State, Zip
FROM G17Nat1
WHERE G17Nat1.UIC = ANY (SELECT CMDPLAN.UIC
FROM CMDPLAN)

Area-UIC List
SELECT DISTINCT UIC INTO AREA_UIC
FROM VALID_UIC
WHERE VALID_UIC.FAC_ID = ANY (SELECT AREA_FACID.FAC_ID
FROM AREA_FACID)

AREA_CLOS_UIC
SELECT UIC
FROM G17Nat1
WHERE G17Nat1.TIER = "5B"
AND G17Nat1.UIC = ANY (SELECT AREA_UIC.UIC

149
```
FROM AREA_UIC)

AREA_ZIPCODE(MapInfo)
SELECT ZIP_CODE
FROM US_ZIPS
WHERE Obj Within objAreaBuffer
ORDER BY ZIP_CODE

Area_G18 ZIP(MapInfo)
SELECT DISTINCT UIC, ZIPCODE, COUNT(UIC) AS UIC_TOTAL
FROM G18CWE
GROUP BY UIC, ZIPCODE
ORDER BY UIC, ZIPCODE

TOTAL_AVAIL
SELECT SUM(UIC_TOTAL) AS TOTAL_AVAIL
FROM Area_G18_ZIP
WHERE Area_G18_ZIP.UIC = ANY (SELECT AREA_CLOS_UIC.UIC
FROM AREA_CLOS_UIC)
AND Area_G18_ZIP.ZIPCODE = ANY (SELECT AREA_ZIPCODE.ZIP
FROM AREA_ZIPCODE)

Yield Curve: The shape of this function assumes diminishing returns in the number of transfers available. Experience suggests that for an average unit of 100 people, approximately half have prior reserve experience and that approximately half of the people in a closing unit will be able to transfer their skills directly to a new unit. The value of the first 100 reservists increases at a nearly linear rate because they provide preferred fills for approximately 50 of the positions of the moving unit. A value of 100 personnel is assigned a utility of 0.9. The incremental value added by each additional person over 100 continues to drop until no marginal gain is expected over 500.

Max Utility: > 250      Min Utility: 0
Decision Parameter 13. IRR Available

**Definition:** Individual Ready Reserve (IRR) Available is the number of IRR members living in the area of the proposed relocation site. This is a Decision Parameter of the size of the prior service market.

**Calculation:** A geographical query returns the total number of IRR members living within a specified distance of the proposed relocation site. This process requires a geocoded version of the IRR file.

\[
\text{TOTAL}_\text{IRR} \text{[Total Number of Available IRR from the Area]}
\]

**Units:** People

**Source File:** IRR

**Query:**
```
AreaIRR(MapInfo)
SELECT ZIPC "ZIP", LEFT$(PMOS, 3) "MOS"
FROM IRR
WHERE Obj Within objAreaBuffer
    AND ZIPC <> "434" AND PMOS <> "435"
ORDER BY ZIPC
(Note: objAreaBuffer is equal to 300 miles)
```

\[
\text{TOTAL}_\text{IRR}
\text{SELECT COUNT(*) AS TOTAL}_\text{IRR}
\text{FROM AreaIRR}
\]

**Yield Curve:** For a typical unit of 100 people, it is assumed that approximately 40 positions could best be filled by IRR members. The recruiting rate for the IRR is approximately 1 percent, so an area that offers 4,000 IRR members is assigned an average utility of 0.5. Above this point, there are diminishing returns. The market begins to exceed the personnel demand of a moving unit and limited recruiting efforts become marginally less effective. The utility of smaller numbers quickly drops off because of the importance of this source of recruits.

\[
\text{Max Utility: } > 10,000 \quad \text{Min Utility: } 0
\]
Decision Parameter 14. Recruit Market

Definition: The Recruit Market Decision Parameter estimates the total number of males who:
1. live in the area of the proposed relocation site
2. Would score in the top half on the Armed Forces Qualification Test (AFQT)
3. Fall into the desired age group (17 - 29 years old)

Calculation: This Decision Parameter sums the entries for all mental categories 1 through 3A, and all ethnic groups for the zip codes of interest in the Qualified Military Available (QMA) file. The version of QMA used contains only the estimates for males within the age range of 17 to 29.

TOTAL_MARKET[Total Non-Prior Service Personnel from the Area]

Units: People

Source File: QMA, US_ZIPS(MapInfo)

ACROPOLIS Table(s): NONE

Query:

QMA(MapInfo)
SELECT LEFT$(ZIP, 5) "ZIPCODE", MWCAT12, MWCAT3A, MBCAT12, MBCAT3A, MHCAT12, MHCAT3A
FROM QMA
WHERE Obj Within objAreaBuffer
ORDER BY ZIP
(Note: objAreaBuffer is equal to 300 miles)

AREA_ZIPCODE(MapInfo)
SELECT ZIP_CODE
FROM US_ZIPS
WHERE Obj Within objAreaBuffer
ORDER BY ZIP_CODE

TOTAL_MARKET
SELECT SUM(MWCAT12+MWCAT3A+MBCAT12+MBCAT3A+
MHCAT12+MHCAT3A) AS TOTAL_MARKET
FROM QMA
WHERE QMA.ZIP = ANY (SELECT AREA_ZIPCODE.ZIP
FROM AREA_ZIPCODE)
**Yield Curve:** Approximately half of a typical unit of 100 reservists is filled by recruits with no prior service. Assuming a recruit rate of 0.25 percent, there must be at least 20,000 people in the area of the proposed relocation site who meet all of the requirements stated above. This value is assigned a typical utility of 0.5. As the number increases, there are diminishing returns. The market begins to exceed the personnel demand of a moving unit and limited recruiting efforts become marginally less effective.

\[ \text{Max Utility: } > 250,000 \quad \text{Min Utility: } 0 \]
Decision Parameter 15. Reassignments

**Definition:** The Reassignments Decision Parameter indicates the fraction of the reservists assigned to the moving unit who currently live within a specified distance (50 miles) of the proposed relocation site.

**Calculation:** This Decision Parameter is calculated by first determining all zip codes that lie within a specified distance of the proposed relocation site (based upon zip code centroid) and then identifying all reservists who both live within one of the identified zip codes (based upon the “ZIP” field of the G18CWE file) and are assigned to the moving unit (based upon the “UIC” field of the G18CWE file). Then the number available reassignments is divided by the total number of reservists assigned to the moving unit.

\[
\frac{\text{TOTAL\_RESERVISTS}}{\text{UIC\_TOTAL}}\]

Where:
- **TOTAL\_RESERVISTS** = Total Number of Available Reservists from the Moving Unit
- **UIC\_TOTAL** = Total Number of Reservists Assigned Moving Unit

**Units:** Ratio

**Source File:** G18CWE, US\_ZIPS(MapInfo)

**ACROPOLIS Table(s):** G18Natl

**Query:**

```sql
SELECT ZIP_CODE
FROM US_ZIPS
WHERE Obj Within objAreaBuffer
ORDER BY ZIP_CODE

G18(MapInfo)
SELECT UIC, LEFT$(ZIP,5) "ZIPCODE", PRI "MOS"
FROM G18CWE
WHERE Obj Within objG18Buffer AND PRI <> ""
ORDER BY UIC, ZIP
INTO G18

Area_G18_ZIP
SELECT DISTINCT UIC, ZIPCODE, COUNT(UIC) AS UIC\_TOTAL
FROM G18
GROUP BY UIC, ZIPCODE
ORDER BY UIC, ZIPCODE
```
TOTAL_RESERVISTS
SELECT SUM(UIC_TOTAL) AS TOTAL_RESERVISTS
FROM Area_G18_ZIP
WHERE Area_G18_ZIP.UIC = MovingUnit.UIC
AND Area_G18_ZIP.ZIPCODE = ANY (SELECT AREA_ZIPCODE.ZIP
FROM AREA_ZIPCODE)

UIC_TOTAL
SELECT UIC_TOTAL
FROM G18Natl
WHERE G18Natl.UIC = MovingUnit.UIC

Yield Curve: The current location will always receive a utility score of 0.0 on this Decision Parameter. For relatively close relocation sites, this function was made to be convex, assigning high utility values to alternatives that are close to the current location.

![Utility Curve](image)

Max Utility: 1.0      Min Utility: 0.0
Decision Parameter 16. Distance to Area Maintenance Support Activity

Definition: Distance to the nearest Area Maintenance Support Activity (AMSA) is calculated as a proxy Decision Parameter for response time and support quality.

Calculation: The straight-line distance from the proposed site to the closest AMSA is calculated using a geocoded version of the AMSA file.

DIST_AMSA[Determine distance to nearest AMSA Site]

Units: Miles

Source Data: AMSA

ACROPOLIS Table(s): NONE

Query:

DIST_AMSA(MapInfo)
SELECT *
FROM AMSA
WHERE Obj Withing ObjDistanceBuffer into TempRZA
(Note: ObjDistanceBuffer is equal to 300 miles)

SELECT Distance((CentroidX(Obj), CentroidY(Obj), FacIDLat, FacIDLong, “mi”))
FROM TempAMSA
ORDER BY Distance INTO TempAMSA.Dist

Yield Curve: The desirability of a relocation site is relatively insensitive to small changes in distance for both close and distant AMSA sites. Little degradation in service is expected if the AMSA can have parts and technicians on site within a couple hours using a car or truck. It is possible that a trainer that breaks down in the morning may be operational for an afternoon training session. At approximately 200 miles (assigned a 0.5 utility) it starts to become impractical to expect same day service and avoid an overnight stay. Eventually it becomes necessary to consider flying rather than driving which is likely to further reduce the responsiveness and effectiveness of the AMSA.

Max Utility: 0  Min Utility: > 500
Decision Parameter 17. Distance to Nearest Equipment Concentration Site

**Definition:** Distance to the nearest Equipment Concentration Site (ECS) provides an indication of the training time that must be used to travel back and forth.

**Calculation:** The straight-line distance from the proposed site to the closest ECS is calculated using a geocoded version of the ECS file.

\[
\text{DIST\_ECS}[\text{Determine distance to nearest ECS}]
\]

**Units:** Miles

**Source Data:** ECS

**ACROPOLIS Table(s):** NONE

**Query:**

```sql
SELECT * 
FROM ECS 
WHERE Obj Withing ObjDistanceBuffer into TempECS 
(Note: ObjDistanceBuffer is equal to 300 miles)

SELECT Distance((CentroidX(Obj), CentroidY(Obj), FacIDLat, FacIDLong, "mi")) 
FROM TempECS 
ORDER BY Distance INTO TempECS.Dist
```

**Yield Curve:** The desirability of an Equipment Concentration Site is relatively insensitive to small changes in distance for both close and distant sites. Typically, a site that can be reached within an hour and ten minutes is not significantly less desirable than one that can be reached in ten minutes. An hour of one-way travel time is not normally considered to be excessive and allows for most of the time to be spent training on a one day training exercise. At approximately 60 miles (assigned a 0.5 utility) it starts to become impractical to expect useful training to be conducted on a day trip and avoid an overnight stay. Eventually it becomes necessary to consider flying rather than driving which is likely to further reduce the desirability of the ECS.

![Utility vs Miles Graph]

**Max Utility:** 0  
**Min Utility:** > 200
Decision Parameter 18. Facility Weekends Used

**Definition:** Facility Weekend Usage provides the number of weekends per month that the facility is currently in use. This Decision Parameter treats a facility as a limited resource that is incrementally depleted as more units are assigned. Since most units require exclusive use of the facility one weekend every month, the number of weekends used normally corresponds to the number of units assigned and is typically limited to four.

**Calculation:** This value is extracted from the "RS_WKND_PM" field of the COMPLEX file.

WKND_USED[Retrieve Number Weekends Facility Used per Month]

**Units:** Weekends per month

**Source Data:** COMPLEX

**ACROPOLIS Table(s):** COMPLEX_

**Query:**

```
WKND_USED
SELECT COMPLEX_FAC_WKND_USED
FROM COMPLEX_
WHERE COMPLEX_FAC_ID = ProposedFacility.FAC_ID
```

**Yield Curve:** Although some exceptions exist, a typical facility offers no utility to a relocating unit if all four weekends are already being used. Although most facilities with three units or less should be able to accommodate a new unit and might be viewed as having equal utility, other issues such as full time administrative space and available equipment storage space make a facility with fewer units currently assigned slightly more desirable.

![Utility vs Weekends per Month Graph](image)

Max Utility: 0  
Min Utility: 4

161
Decision Parameter 19. Available MOS from Closing Units

Definition: This Decision Parameter provides the number of reservists from closing units in the area of the proposed relocation site who possess a Military Occupational Specialty (MOS) needed by the relocating unit. These people provide a preferred pool of trained and qualified recruits.

Calculation: The number of personnel records (from the G18CWE file) that meet all the following requirements are counted:

1. The reservist is assigned to a unit that is scheduled to close (a TIER="5B" entry in the G17 file is used to produce a list of closing units).
2. The reservist lives in a zip code in the area of the proposed relocation site.
3. The reservist’s primary MOS is needed by the moving unit.

If the three MOS groups with the largest number of members in the moving unit account for more than 50 percent of the total unit membership, then only those three MOS’s are considered. Otherwise all MOS’s required by the moving unit are considered as an MOS of interest.

TOTAL_CLOS_MOS[Total Number of Available Reservists from Area Closing Units with MOS’s of Interest]

Units: Number of people

FROM    Area_G18_MOS
WHERE   Area_G18_MOS.MOS = ANY (SELECT MOS_INTEREST.MOS
                            FROM MOS_INTEREST)
            AND Area_G18_ZIP.UIC = ANY (SELECT AREA_CLOS_UIC.UIC
                            FROM AREA_CLOS_UIC)
            AND Area_G18_ZIP.ZIPCODE = ANY (SELECT AREA_ZIPCODE.ZIP
                            FROM AREA_ZIPCODE)

Yield Curve: The shape of this function assumes diminishing returns on the number of transfers available. Experience suggests for an average unit of 100 people, that it is unusual to expect more than a third of the members to transfer from closing units with the proper MOS. Of the reservists in this category, only half typically transfer, so a value of 60 personnel is assigned a utility of 0.9. The incremental value added by each additional person over 60 continues to drop until no marginal gain is expected over 250.

Max Utility: > 250       Min Utility: 0

165
Decision Parameter 20. Available MOS IRR

**Definition:** This Decision Parameter provides the number of Individual Ready Reserve members who live in the area of the proposed relocation site and who possess a Military Occupational Specialty (MOS) needed by the relocating unit. These people provide a preferred pool of trained recruits.

**Calculation:** The number of IRR members who possess an MOS needed by the moving unit and who live in the area of the proposed relocation site (based upon the zip code of their home of record in the IRR file) are counted. If the three MOS groups with the largest number of members in the moving unit account for more than 50 percent of the total unit membership, then only those three MOSs are considered. Otherwise all MOSs required by the moving unit are considered as an MOS of interest.

TOTAL_IRR_MOS[Total Number of Available Reservists from the IRR with MOS’s of Interest]

**Units:** Number of People

**Source File:** IRR, G18CWE

**ACROPOLIS Table(s):** G18Natl

**Query:**

```sql
SELECT MOS, COUNT(*) AS MOS_COUNT INTO NoAssnX MOS FROM G18Natl
WHERE G18Natl.UIC = MovingUnit.UIC
GROUP BY MOS
ORDER BY COUNT(*) DESC

MOS_TOTAL
SELECT SUM(MOS_COUNT) AS MOS_TOTAL FROM NoAssnX MOS

MOS_TOP3
SELECT TOP 3 MOS_COUNT FROM NoAssnX MOS

MOS_INTEREST
IF MOS_TOP3/MOS_TOTAL < 50%
SELECT MOS INTO MOS_INTEREST
FROM NoAssnX MOS
ORDER BY MOS
```

167
IF MOS_TOP3/MOS_TOTAL > 50%
    SELECT TOP 3 MOS INTO MOS_INTEREST
    FROM NoAssnMOS
    ORDER BY MOS

IRR(MapInfo)
SELECT ZIPC "ZIP", LEFT$(PMOS, 3) "MOS"
FROM IRR
WHERE Obj Within objAreaBuffer and ZIPC <> "" AND PMOS <> ""
ORDER BY ZIPC
INTO IRR

TOTAL_IRR_MOS
SELECT SUM(UIC_TOTAL) AS TOTAL_CLOS_MOS
FROM IRR
WHERE IRR.MOS = ANY (SELECT MOS_INTEREST.MOS
                       FROM MOS_INTEREST)

Yield Curve: IRR members represent preferred recruits for less than half of the positions of a typical moving unit (approximately 40 out of 100) because of issues such as seniority and changes in the skills associated with an MOS. The success rate of recruiting IRR members is approximately 1 out of 100, so 4000 IRR members in the area of the relocation site are required to provide sufficient market to fill the 40 positions. The value of 4000 is assigned the average utility value of 0.5. As the IRR market increases it exceeds the needs of the moving unit and makes the limited recruiting efforts marginally less effective.

APPENDIX D. ARIES SDSS CODE LISTINGS.

This appendix contains the detailed code listings of each Visual and Map Basic module that comprises the ARIES SDSS prototype application.

Index

Module 1. SUBMAIN PROCEDURE.................................................................181
Module 2. SDSS USER INTERFACE ............................................................183
Module 3. ARIES PUBLIC DECLARATIONS..................................................213
Module 4. ARIES PROCEDURES LIBRARY ...............................................221
Module 5. OLE PROCEDURES LIBRARY .................................................231
Module 6. OLE OBJECT CLASS DEFINITION .......................................239
Module 7. MAPBASIC PUBLIC DECLARATIONS ......................................243
Module 8. SPATIAL SELECTION PROGRAM ..............................................257
Module 1. SUBMAIN PROCEDURE

Purpose: Submain Procedure immediately executes upon ARIES application loading in memory. It is a standard Visual Basic initialization procedure. For the purposes of the ARIES SDSS, the procedure loads the splash screen for 30 seconds, initializes all OLE connections with MapInfo components and displays the main SDSS User Interface form.

Source Type: Visual Basic for Applications

Source File: SUBMAIN.BAS

**********************************************************************************************

SetStatusText

This is a standard method that MapInfo looks for in its Callback
object. If MapInfo finds this method in the Callback object, it
will get called automatically every time the text in MapInfo's
status bar text changes. The string passed in is a tab-delimited
string containing each of the status bar "Fields", i.e. - the
first field is the zoom, scale, or cursor location, the second field
is the editable layer, etc.

**********************************************************************************************

Public Sub SetStatusText(ByVal cStatusText As String)
    cProcName = "SET_STATUS_TEXT"
    Dim cNewText As String
    cNewText = GetField(cStatusText, vbTab, 1)  'get first field in tab-
delimited string
    If Not (cNewText = "") Then
        frmAriesMain!AriesStatusBar.Panels(4).Text = cNewText
    End If
End Sub
Module 7. MAPBASIC PUBLIC DECLARATIONS

Purpose: A library module that initializes all public variables and constants for communicating with the integrated mapping component.

Source Type: Visual Basic for Applications

Source File: libMAPBASIC.BAS

Code Listing:

```
Attribute VB_Name = "libMAPBASIC"

'=================================================================================================================================='
' MapInfo version 4.0 - System defines
'=================================================================================================================================='
' This file contains defines useful when programming in the MapBasic language. There are three versions of this file:
' MAPBASIC.DEF - MapBasic syntax
' MAPBASIC.BAS - Visual Basic syntax
' MAPBASIC.H - C/C++ syntax
'=================================================================================================================================='
' The defines in this file are organized into the following sections:
' General Purpose defines:
' Macros, Logical constants, Angle conversion, Colors
' ButtonPadInfo() defines
' ColumnInfo() defines
' CommandInfo() defines
' FileAttr() defines
' IntersectNodes() parameters
' LayerInfo() defines
' MapperInfo() defines
' MenuItemInfoByID() and MenuItemInfoByHandler() defines
' ObjectGeography() defines
' ObjectInfo() defines
' SearchInfo() defines
' SelectionInfo() defines
' Server statement and function defines
' StringCompare() return values
' StyleAttr() defines
' SystemInfo() defines
' TableInfo() defines
' WindowInfo() defines
' Abbreviated list of error codes
' Backward Compatibility defines
'=================================================================================================================================='
' This file is converted into MAPBASIC.H by doing the following:
' - concatenate MAPBASIC.DEF and MENU.DEF into MAPBASIC.H
' - search & replace ""n at begining of a line with "/n"
' - search & replace "Define" at begining of a line with "#define"
' - delete the following sections:
' * General Purpose defines: Macros, Logical Constants, Angle
' Conversions
' * Abbreviated list of error codes
' * Backward Compatibility defines
' * Menu constants whose names have changed
' * Obsolete menu items
'=================================================================================================================================='
' This file is converted into MAPBASIC.BAS by doing the following:
' - concatenate MAPBASIC.DEF and MENU.DEF into MAPBASIC.BAS
' - search & replace "Define <name>" with "Global Const <name> ="
' e.g. "<Define {I-I-Z}\+{I-I-Z}>" with "Global Const \0 \1 using Brief
```

' MapInfo version 4.0 - Menu Item Definitions

This file contains defines useful when programming in the MapBasic
language. The definitions in this file describe the standard MapInfo
functionality available via the "Run Menu Command" MapBasic statement.

The defines in this file are organized to match the sequence of
declarations in the MAPINFO.MNU file, which in turn reflects the
organization of the MapInfo menus and buttonpads.
