# Abstract

This report describes a case study to determine whether computer-aided prototyping techniques provide a cost-effective means for re-engineering legacy software. The case study consists of developing a high-level modular architecture for the existing US Army Janus combat simulation system, and validating the architecture via an executable prototype using the Computer Aided Prototype System (CAPS), a research tool developed at the Naval Postgraduate School.

The case study showed that prototyping can be a valuable aid in re-engineering of legacy systems, particularly in cases where radical changes to system conceptualization and software structure are needed. The CAPS system enabled us to do this with a minimal amount of coding effort.
Re-engineering the Janus(A) Combat Simulation System

Abstract

This report describes a case study to determine whether computer-aided prototyping techniques provide a cost-effective means for re-engineering legacy software. The case study consists of developing a high-level modular architecture for the existing US Army Janus(A) combat simulation system, and validating the architecture via an executable prototype using the Computer Aided Prototype System (CAPS), a research tool developed at the Naval Postgraduate School.

The case study showed that prototyping can be a valuable aid in re-engineering of legacy systems, particularly in cases where radical changes to system conceptualization and software structure are needed. The CAPS system enabled us to do this with a minimal amount of coding effort.

I. PROBLEM STATEMENT

1. OVERVIEW

We address the need to modernize the software of the Janus(A) systems into a maintainable and evolvable structure. This research develops

- a high-level modular architecture for the existing Janus(A) systems using CAPS;

- an implementation of the design using the Ada95 programming language. The higher level goal of this research is to evaluate the effectiveness of computer-aided prototyping and software evolution tools when applied to legacy software, as opposed to prototype software that is initially developed in the context of the CAPS system and its prototyping language PSDL.

A good modular design is an essential feature of every maintainable and evolvable software system. Such designs partition large systems into sets of highly cohesive and loosely coupled components and minimize the effect of changes to individual components. The high-level architecture, in its executable form, enables designers of the Janus(A) systems to incrementally re-engineer the existing software system and to easily add new functionalities to the Janus(A) systems. The Computer Aided Prototyping System (CAPS) provides automation support for future evolution of the Janus(A) systems while reusing existing code to the maximum degree possible.

This experiment also serves as a reality check for computer-aided prototyping. CAPS is a research tool that has been developed to show the feasibility of providing significant computer aid for software evolution when that software has been developed using a prototyping language PSDL that has been specifically designed to support prototyping and evolution. This research evaluates the effectiveness of these same tools and techniques for re-engineering a piece of legacy code that was not designed to support software evolution. The experiment helps determine whether computer-aided prototyping techniques provide a cost effective means for re-engineering legacy software.

The experiment is based on the premise that the re-engineering problem for the Janus(A) system is typical of the re-engineering problems facing many older software systems used by DoD, and that the capability for rapid construction, evaluation, and modification of software architectures will help to speed up the process of recovering high-level design information from old code and restructuring the code so that old functions can be used in new ways and can be extended to include new functionality. We summarize the lessons learned from this experiment to suggest several useful improvements to the CAPS system as well as uncover critical problems that should be addressed to enable more effective and less expensive re-engineering of legacy software systems.
2. BACKGROUND

Janus(A) is a software-based war game which simulates ground battles between two adversaries. It is an interactive two-sided, closed, stochastic, ground combat simulation that features precise color graphics. Janus is "interactive" in that command and control functions are entered by military analysts who decide what to do in crucial situations during simulated combat. The current version of Janus consists of a large number of FORTRAN modules, organized as a flat structure and interconnected with one another via FORTRAN COMMON declarations, resulting in a software structure that makes modification to Janus very costly and error-prone.

As explained in Janus’ Software Design Manual, Janus manipulates a large number of files to generate data structures and to draw input parameters for its simulation algorithms. Data structures in Janus are FORTRAN arrays shared by relevant subroutines via COMMON statements. As such, and following the tradition of FORTRAN data structure definition, a weapon system’s operational parameters are spread across a number of arrays and are identified by an array index value. Information regarding a particular system is therefore not encapsulated within a single construct as would be the case with more modern programming techniques and languages such as ADA. Furthermore, Janus algorithms are parameterized. That is, the behavior of a weapon system’s simulation algorithm relies on data drawn from that weapon system’s array entries. This strongly suggests that, to change the behavior of a weapon system, one must be able to edit that weapon’s corresponding array entries. This is currently supported by the Janus interface module through a complex menu-driven editing process. However, altering the nature of the simulation algorithm for a given weapon system is not currently supported by Janus. Sophisticated programming skills and a clear understanding of Janus’ data representation and software is needed. A modular hierarchical software architecture is needed to ease the understanding and reduce the risk and cost in modifying the Janus system. We try to extract the communication structures from the old code, and to embody those structures in a clean high level PSDL description that can drive the automated program generation capabilities of CAPS, and can enable easy arrangement and enhancement of those communication structures.

3. GUIDING PRINCIPLES

Our high-level modular software architecture encapsulates the major functions of Janus into loosely connected subsystems, with a well-defined interface between the subsystems. The architecture is the result of a conceptual reformulation based on the principles of data abstraction and generalization. Data abstraction decouples the software interfaces from the detail of data representations, thus limiting the impact of future representation changes. Generalization factors out the properties common to many different but similar data types, thus simplifying code and eliminating redundancy via polymorphic programming. The modular structure allows engineers to re-engineer and extend the Janus system in a piece-by-piece fashion.

The capability to test and evaluate early models of such architectures is essential to mitigate the risks of error inherent in any major problem reformulation. Our thesis is that
early prototyping is a valuable tool in software re-engineering because it explores conceptual
ingconsistencies and missing pieces early in the process. Such errors are easy to correct at this
stage because there are fewer implementation details to be undone and then redone. Moreover, the availability of an executable software architecture enables engineers to test
and evaluate modified components for correctness and efficiency.

The modular architecture also promotes the use of reusable components in Janus
evolution. A representation for the software components must exist in order to reuse
software components in a repository. Under the 3C model, a software component can be
represented in terms of its concept, content and context.

- The concept of a software component describes the purpose and behavior of the
  component. It is usually represented by a brief component abstraction in the form of a
  formal/informal specification, or a software wrapper with identifiable attributes and
  keywords.

- The content of a software component consists of the data structures and algorithms
  needed to implement the software. It may contain several alternatives for different
  combinations of time/space requirements.

- The context of a software component describes where and how a component is used
  and what it relies on in its environment to work properly. The context is particularly
  important in large scale software reuse because successful software reuse tends to be
domain specific.

The availability of an executable architecture enables testing components in their
proper contexts, thus reducing the risk of incompatibility and mitigating the risk of
improperly formulated concepts for reusable components.
II. SUMMARY OF THE MOST IMPORTANT RESULTS

This report summarizes the work done on the Modular Software Architecture of Janus (A) project for the period from April 1998 to December 1998. The research of this project is aimed at developing a software architecture to support the re-engineering of the Janus Combat Simulation System. In these past seven months, we have analyzed the Janus Fortran source code, interviewed Janus domain experts, developed an Object-Oriented architecture for the Janus Combat Simulation subsystem, and validated the architecture with an executable prototype.

1. THE LEGACY SYSTEM

Janus is a software-based war game that simulates ground battles between up to six adversaries. It is an interactive, closed, stochastic, ground combat simulation that features precise color graphics. Janus is "interactive" in that command and control functions are entered by military analysts who decide what to do in crucial situations during simulated combat. The current version of Janus operates on a Hewlett Packard workstation and consists of a large number of FORTRAN modules, organized as a flat structure and interconnected with one another via FORTRAN COMMON blocks, resulting in a software structure that makes modification to Janus very costly and error-prone. There is a need to modernize the Janus software into a maintainable and evolvable system and to take advantage of modern Personal Computers to make Janus more accessible to the Army. TRAC-Monterey is re-engineering Janus into an object-oriented software system that is written in the C++ programming language and operates on Personal Computers. Prior to rewriting Janus in C++, the Software Engineering group at the Naval Postgraduate School is asked to extract the existing functionality through reverse engineering and to produce an object-oriented architecture that supports existing and required enhancements to Janus functionality.
2. THE RE-ENGINEERING PROCESS

The research team consists of four professors (Luqi, V. Berzins, M. Shing, and J. Guo) and two CS students (MAJ J. Williams and CPT M. Saluto). In addition, two other CS students (CPT. M. Merrell and Lt.Jg. Ilker Duranlioglu) also participated in the initial phase of the project.

2.1 SYSTEM UNDERSTANDING

The first step in our process, system understanding, took the form of a series of brief meetings with the client, TRAC-Monterey, which also included a short demonstration of the current software system. We asked questions and made notes on the system’s operation and its current functionality. We paid particular attention to the client’s view of the system to gather their ideas on its strengths, weaknesses, and desired and undesired functionality. Additionally we collected copies of the Janus User’s Tutorial manual, Janus User Manual, the Software Design Manual from a previous version of Janus (3.X/UNIX), and the Janus Version 6.88 Release Notes. Our goal was to gather as much information as we could about the currently existing system to aid in gaining a clearer understanding of its present functionality. The intent of this procedure was to ensure that the systems’ current functionality was not lost nor misrepresented in the transformation into a more abstract, modular format.

2.2 REVERSE-ENGINEERING

The focus of this step was to abstractly capture the system’s functionality and then produce system models that would most accurately represent that functionality.

Armed with the Janus source code, we proceeded to divide the code by directories amongst the team members. Each team member was assigned roughly six to seven directories to explore, examine and gather information. Using strictly manual techniques with UNIX commands and review procedures, we were able to get a fairly good idea of what each subroutine was designed to do. We also used the Software Programmers’ Manual to aid in understanding each subroutine’s function. In doing so we were able to group the subroutines by functionality to get a better understanding of the major data flows between programs. Using that knowledge, we developed functional models from
the data flows. We used an automated tool known as CAPS, Computer-Aided Prototyping Systems, version 2.0, developed by Professor Luqi and the Software Engineering group at the Naval Postgraduate School, to assist in developing the abstract models. CAPS allowed us to rapidly graph the gathered data and transform it into a more readable and usable format. Additionally, CAPS enabled us to develop our diagrams separately with the associated information flows and stream definitions, and then join them together still under the CAPS environment, where they can be used to generate an executable model of the architecture.

Figure 1 shows the resultant top-level structure of the existing Janus system. It consists of five subsystems - cs_data_mgmt, scenario_db, janus, jaaws, and postp. The cs_data_mgmt subsystem manages combat system databases. The scenario_db subsystem manages the different scenarios and simulation runs in the system. The janus subsystem simulates the ground battles. The jaaws subsystem allows analyst to perform post-simulation analysis and the postp subsystem allows Janus users to view simulation reports.

![Figure 1. Top-level communication structure of the existing Janus software](image)
2.3 TRANSFORMATION OF FUNCTIONAL MODELS TO OBJECT MODELS

Next, we proceeded to develop object models of the Janus System using the aforementioned materials and products, to create the modules and associations amongst them. This was probably the most difficult and most important step. It required a great deal of analysis and focus to mentally transform the currently scattered sets of data and functions into small, coherent and realizable objects, each with its own attributes and operations. In performing this step, we used our knowledge of object-oriented analysis and applied the OMT techniques and the UML notations to create the classes and associated attributes and operations. This was a crucial step because we had to ensure that the classes we created accurately represented the functions and procedures currently in the software. We used the HP-UNIX systems at the TRAC-Monterey facility to run the Janus simulation software to aid in verifying and/or supplementing the information we obtained from reviewing the source code and documentation. This step enabled us to better analyze the simulation system, gaining insight into its functionality and further concentrate on module definition and refinement.

2.4 REFINEMENT OF THE OBJECT MODELS AND THE DEVELOPMENT OF THE OBJECT ORIENTED ARCHITECTURE

During this phase of the project, the re-engineering team met several times each week for a period of two and a half months to discuss the object models for the Janus core elements and the object-oriented architecture for the Janus System. They presented the findings to the Janus domain experts from TRAC-MTRY and Rolands & Associates at least once per week to get feedback on the models and architectures being constructed. In addition, the re-engineering team also presented the findings to members of the OneSAF project, the Combat21 project, and the National Simulation Center. Based on the feedback from the domain experts, the re-engineering team revised the object models for the Janus core elements (Appendix E) and developed a 3-tier object-oriented architecture for the Janus System (Appendix A).
3. SOFTWARE ARCHITECTURE FOR THE JANUS COMBAT SIMULATION SUBSYSTEM

3.1 ARCHITECTURE OF THE EXISTING JANUS CODE

Central to the existing Janus Combat Simulation Subsystem is the program RUNJAN, which is the main event scheduler for the Janus simulation. RUNJAN determines the next scheduled event (called "process" in the Janus manual) and executes that event. If the next scheduled event is a simulation event, RUNJAN will advanced the game clock to the scheduled time of the event and perform that event. RUNJAN categorizes all events into 17 events to be handled by the following event handlers:

1. DOPLAN - interactive and CAC planning activity
2. MOVEMENT - simulation event to update unit positions which have been changed due to movement
3. DOCLOUD - simulation event to create and update status of smoke and dust clouds, and redraw them if necessary
4. STATEWT - periodic activity to write unit status data to disk
5. RELOAD - simulation event to plan and execute the direct fire events
6. INTACT - activity to update the graphics displays
7. CNTRBAT - simulation event to detect artillery fires
8. SEARCH - simulation event to update target acquisitions, choose weapons against potential targets, and schedule potential direct fire events
9. DOCHEM - simulation activity to create chemical clouds and to transition units to different chemical states
10. FIRING - simulation event to evaluate direct fire impact and to execute an indirect fire mission
11. IMPACT - simulation event to evaluate and update the results of a round impacting
12. RADAR - simulation event to update an air defense radar state, and to schedule a direct fire event for "normal" radar
13. COPTER - simulation event to update a helicopter state
14. DOARTY - simulation event to schedule an indirect fire mission
15. DOHEAT - simulation event to update units' heat stress
16. DOCKPT - activity to perform automatic checkpoints
17. ENDJAN - housekeeping activity to end the simulation

3.2 PROBLEMS WITH THE EXISTING EVENT SCHEDULER

The existing event scheduler uses global arrays and matrices to maintain the attributes of the objects in the simulation. Hence, one of the major tasks in designing an object-oriented architecture for the Janus combat simulation subsystem is to distribute the event handling functions to individual objects. Moreover, it is necessary to redefine some event categories in order to provide a uniform framework to eliminate redundant coding of the same or similar functions and to take advantage of dynamic dispatching of event handling functions in the object-oriented architecture. For example, the process for a unit to search for targets, select weapons, prepare direct fire, and execute direct fire differs depending on whether a unit has a normal radar, special radar, or no radar at all. Existing Janus uses the RADAR event handler to carry out the whole process if the unit has normal radar. It uses SEARCH, RADAR and RELOAD event handlers to carry out the process if the unit has special radar, and uses the SEARCH and RELOAD event handlers to carry out the process if the unit has no radar at all.

Interactions between the simulation engine and the world modeler are performed implicitly within the various event handlers in the existing Janus. Such interactions are made explicit in the new architecture in order to provide a uniform framework to update World Model objects during the simulation.

In order to allow the Janus implementation to take advantage of the reusable components provided by Tapestry, details of the event handlers for interactive and CAC planning activities, writing of unit status data to disk, updates of the graphics displays, and automatic checkpoints are not provided because of all these activities involve either the graphical user interface or the persistent storage of the objects. However, we do have recommendations regarding the design of the history mechanism (see Section 5).
3.3 THE PROPOSED OBJECT-ORIENTED ARCHITECTURE FOR THE JANUS COMBAT SIMULATION SUBSYSTEM

The new architecture uses an explicit priority queue of event objects to schedule the simulation events. Each event object has an associated simulation object, which is the target of the event. There are 14 event groups, which correspond to the 14 event subclasses shown in Appendix B. Note that an object-oriented approach enables us to reduce the number of event types needed in the simulation. Depending on the subclass that an event object belongs to, the "execute" method will invoke the corresponding event handler of the associated simulation object to handle the event (Appendix C). The simulation object superclass defines the interface of the event handlers for the event groups, and provides an empty body as the default implementation for the event handlers. The methods are overridden by the actual event handler code at the subclasses that have non-empty actions associated with the events, as shown in Appendix D.

The above architecture enables a very simple realization of the main simulation loop (see page G-31). The code for the event control loop follows:

```
initialization;
While not_empty(event_queue) loop
  e := remove_event(event_queue);
  e.execute();
End loop;
finalization;
```

Note that this same code handles all kinds of events, including those for future extensions that are yet to be designed. Event objects are created and inserted into the event queue either by the initialization procedure at the beginning of the simulation, by the constructors of the objects, or by the actions of other event handlers. Depending on the actual implementation of when and how events are inserted into the priority event queue, it may be necessary to allow events to change their priorities while waiting in the queue.

World Model object subclasses (with names starting with the "WM" prefix) are created to provide specialized methods for the world modeler to update the objects from other simulators. Information concerning objects local to the Janus simulator can be broadcast over the simulation network either periodically by an active world modeler object, or by individual local objects whenever they update their own states.
4. DEVELOPMENT OF AN EXECUTABLE PROTOTYPE USING CAPS

In order to validate the proposed architecture and to refine the interfaces of the Janus subsystems, we developed an executable prototype using CAPS. Figure 2 shows the top-level structure of the prototype, which has four subsystems: Janus, GUI, JAAWS and the POST-PROCESSOR. Among these four subsystems, the Janus and the GUI subsystems (depicted as double circles) are made up of sub-modules shown in Figures 3 and 4, while the JAAWS and the POST-PROCESSOR subsystems (depicted as single circles) are mapped directly to objects in the target language. After we entered the prototype design using CAPS, we use the CAPS execution support system to generate the code that interconnects and controls these subsystems. (Refer to Appendix F for the PSDL specification of the prototype and Appendix G for the target Ada/C code for the implementation.)

Due to time and resource limitations, we only developed the prototype for a very small simulation run, which consists of a single object (a tank) moving on a two-dimensional plane, 3 event subclasses (move, do_plan, and end_simulation), and 1 kind of post-processing statistics (fuel consumption). In addition, a simple user interface was developed using CAPS/TAE (Figure 5). The resultant prototype has over 6000 lines of program source code and contains enough features to exercise all parts of the architecture. The code that handles the motion of a generic simulation object was very simple, but it was designed so that it would work in both two and three dimensions without modification (currently the initialization and the movement plan of the tank object never call for any vertical motion). The code was also designed to be polymorphic, just as was the main event loop. This means the same code will handle the motion of all kinds of simulation objects without any modifications, including even new types of simulation objects that are part of future enhancements to Janus and have not yet been designed or implemented (see page G-76 and G-79).
Figure 2. Top-level decomposition of the executable prototype
Figure 3. The JANUS subsystem of the executable prototype
Figure 4. The GUI subsystem of the executable prototype
Figure 5. The Graphical User Interface of the executable prototype
5. LESSONS LEARNED

Our prototyping experiment showed that the proposed object-oriented architecture allows design issues to be localized and provides easy means for future extensions. We started out with a prototype consisting of only two events subclasses (move and end_simulation) and were able to add a third event subclass (do_plan) to the prototype without modifying the event control loop of the Janus combat simulator.

We also demonstrated the use of inheritance and polymorphism to efficiently extend/specialize the behavior of combat units. For example, to implement the move_update_object method of a tank subclass which uses the general-purpose method from its superclass to compute its distance traveled and a specialize algorithm to compute its fuel consumption, we simply include 1 statement to invoke the move_update_object method of its superclass followed by 3 lines of code to update its fuel consumption. Moreover, other combat unit subclasses can be added easily to the prototype without the need to modify the event scheduling/dispatching code.

The prototype also resulted in the following refinements to the proposed architecture:

1. Instead of a procedure with no return value, change the Execute_Event operation to return the time at which the next event is to be scheduled for the same simulation object, and introduce a special time value "NEVER" to indicate the no next event is needed. The proposed change turns the communication between the event dispatcher and the simulation objects from a peer-to-peer communication into a client-server communication. This change eliminates the need for the simulation objects to know the details of the event queue and allows the event dispatcher to use a single statement to schedule all recurring events for all event types. It would also eliminate the need for the write-status event (see Appendix B, page B-1).

2. Instead of recording the history of a simulation run in terms of set of data files, model the simulation history as a sequence of events. The proposed change provides a simple and uniform way to handle history records for all events, and allows the same modular architecture to be use for real-time simulation as well as post-simulation analysis. This also provides the greatest possible resolution for
the event histories, which implies that any quantity that could have been calculated during the simulation can also be calculated by a post-simulation analysis of the event history, without any loss of accuracy. The only constraint imposed by this design refinement is that the simulation objects in the events must be copied before being included in the simulation history, to protect them from further changes of state as the simulation proceeds. This constraint is easy to meet because the process of writing the contents of an event object to a history file will implicitly make the required copy.

The prototyping effort also exposed a design issue – should null events appear in the event queue? A null event is one that does not affect the state of the simulation, such as a move event for an object that is currently stationary. The prototype version adopted the position that such events should not be put in the event queue, since this corresponds to current scheduling policies in Janus, and appears at first glance to improve efficiency.

Our experience with the development of the prototype suggests that this decision complicates the logic and may not in fact improve efficiency. In particular, the process create_new_events (see Figure 3) could be eliminated if we allowed null events. This process scans all simulation objects once per simulation cycle to determine if any dormant objects have become active, and if so, schedules events to handle their new activity. The alternative is to have the constructor of each kind of simulation objects schedule all of its initial events, and to have each event handler specify the time of next instance of the same event even if there is nothing for it to do currently. Handlers might still set the time of its next event to NEVER in the case of a catastrophic kill; however this is reasonable only if it is impossible to repair or restore the operation of the units that have suffered a catastrophic kill.

The reasons why this design change may improve efficiency in addition to simplifying the code are that:

(1) the check for whether a dormant object has become active is done less often - once per activity of that object, rather than once per simulation cycle,

(2) executing a null event is every fast – a few instructions at most, so the “unnecessary” null events will not have much impact on execution time, and
the computation to find and test all simulation objects periodically would be eliminated.

One recommendation is to allow null events in the event queue, and to explicitly schedule every kind of events for every object unless it is known there cannot be any non-empty events of that type in any possible state of the object. For example, under the proposed scheduling policy, immobile or irrecoverably damaged objects would not need to schedule future move events, but those that are currently at their planned positions would need to do so, because a change of plan would cause them to move again in the future, even though they are not currently moving.

6. CONCLUSION

Our experience in this case study suggests that prototyping can be a valuable aid in re-engineering of legacy systems, particularly in cases where radical changes to system conceptualization and software structure are needed.

In particular, we found that constructing even a very thin skeletal instance of the proposed new architecture raised many issues and enabled us to correct, complete, and optimize the architecture for both simplicity and performance.

The computer-aided prototyping tools in the CAPS system enabled us to do this with a minimal amount of coding effort. The bulk of the code was generated automatically, enabling us to concentrate on system structuring issue, to consider and evaluate various alternatives, and to improve the design while doing detailed manual implementation for only a few pages of critical code.

Artillery can generate 4 types of clouds (HC, WP, BS, Dust). The algorithm for computing the artillery smoke clouds uses 7 sets of coefficients (A, B, T, P, Q, R, S). Each set of the coefficients consists of 4 attributes (Length, Width, Thick, Height). This data is used within the Janus smoke model's mathematical formulas to determine, over time, the shape of the smoke cloud, the height of the bottom of the cloud off the ground, and the cloud thickness. The data sources is the US Army Atmospheric Smoke Lab. See pg 82 of the CSDATA Manual.

/* PURPOSE:
* This file encapsulates the TAE Plus panel: gui_3
* These routines enable panel initialization, creation, and destruction.
* Access to these routines from other files is enabled by inserting
* '#include "pan_gui_3.h"'. For more advanced manipulation of the panel
* using the TAE routines, the panel's Id, Target, and View are provided.
* 
* NOTES:
* For each parameter that you have defined to be "event-generating" in
* this panel, there is an event handler procedure below. Each handler
* has a name that is a concatenation of the parameter name and "_Event".
* Add application-dependent logic to each event handler. (As generated
* by the WorkBench, each event handler simply logs the occurrence of the
* event.)
* 
* For best automatic code merging results, you should put as many
* modifications as possible between the lines of the MERGE NOTE comments.
* Modifications outside the MERGE NOTES will often merge correctly, but
* must sometimes be merged by hand. If the modifications cannot be
* automatically merged, a reject file (*.rej) will be generated which
* will contain your modifications.
* 
* REGENERATED:
* The following WorkBench operations will cause regeneration of this file:
* The panel's name is changed (not title)
* For panel: gui_3
* 
* The following WorkBench operations will also cause regeneration:
* An item is deleted
* A new item is added to this panel
* An item's name is changed (not title)
* An item's data type is changed
* An item's generates events flag is changed
* An item's valids changed (if item is type string and connected)
* An item's connection information is changed
* For the panel items:
* enter_new_plan, get_re_30, get_st_27, get_user_in_21,
* get_x, get_y
* 
* CHANGE LOG:
* MERGE NOTE: Add Change Log entries BELOW this line.
* 2-Nov-98 Initially generated...TAE
* MERGE NOTE: Add Change Log entries ABOVE this line.

PURPOSE:
This the main program of an application generated by the TAE Plus Code Generator.

REGENERATED:
This file is generated only once. Therefore, you may modify it without impacting automatic code merge.

NOTES:
To turn this into a real application, do the following:

1. Each panel that has event generating parameters is encapsulated by a separate file, named by concatenating the string "pan_" with the panel name (followed by a ".c"). Each parameter that you have defined to be "event-generating", has an event handler procedure in the appropriate panel file. Each handler has a name that is a concatenation of the parameter name and the string "_Event". Add application-dependent logic to each event handler. (As generated by the WorkBench, each event handler simply logs the occurrence of the event.)

2. To build the program, type "make". If the symbols TAEINC, ..., are not defined, the TAE shell (source) scripts $TAE/bin/csh/taesetup will define them.

ADDITIONAL NOTES:
1. Each event handler has two arguments: (a) the value vector associated with the parameter and (b) the number of components. Note that for scalar values, we pass the value as if it were a vector with count 1.

Though it's unlikely that you are interested in the value of a button event parameter, the values are always passed to the event handler for consistency.

2. You gain access to non-event parameters by calling the Vm package using the targetId Vm objects that are created in Initialize_All_Panels. There are macros defined in global.h to assist in accessing values in Vm objects.

To access panel Id, target, and view, of other panels, add an "#include" statement for each appropriate panel header file.
